On the other hand, there is no difficulty in agreeing that strong antiseptics, bacterial suspensions, and, above all, hypertonic solutions do act in suppressing leucocytic movements. This is clearly shown by experiments made by mixing the blood and the test fluid in the emigration tubes before clotting takes place. Such experiments show that some antiseptics—such as carbolic acid—powerfully suppress emigration, whilst others—such as mercuric salts and the neutral hypochlorous solutions—have comparatively little action. But of more practical significance in determining the possible injurious effects produced by the various applications on the physiological processes is the observation made on the wound itself as to whether there is a good flow of laudable pus. If there is, we may be sure that the application is not doing much harm to the tissues, and that the physiological processes remain active. In this connexion it may be noted that Sir Almroth Wright points out "that the practitioner of to-day has been educated up to expect to find, within a few hours after washing out an infected wound with antiseptics, as much pus as when he last came to dress it"; and that hypertonic salt solution will, as long as its concentration is maintained, arrest all suppurative processes and "give us a wound as clean and as free from pus as meat." The inevitable conclusion from this is that in practice, treatment by hypertonic saline, by interfering with the activities of the leucocytes, renders ineffective the only defence there is against the streptococcus and staphylococcus, whilst, with the application of an antiseptic or of physiological saline, this defence comes again into action.

But some do not view with satisfaction a good flow of pus from a badly infected wound, and it is not uncommon to hear the contemptuous expression "pus poulitice." Certainly if the pus is stale, and has become "corrupted," it is noxious, but if fresh, it is efficiently doing its work of combating the organisms. Our aim must therefore be to remove the pus before it becomes corrupted, and if possible to destroy the organisms which corrupt it. The methods of removing pus are, of course, by constant irrigation and occasional flushing, and in deciding between these, it must be remembered that the use of irrigating fluids, even of physiological saline, if delivered below body temperature, will do harm by retarding the activities of the leucocytes. The possibility of destroying the organisms brings us to the consideration of antiseptics.

3. Antiseptics.

The attempt to destroy organisms in wounds is made in two ways—(1) by washing out with lotions, (2) by the application of dressings. In connexion with the washing out of a wound, it will be recognized that, although, as has been observed, the greater part of the wash will be thrown down the sink, a residue will remain in the recesses and pockets; and also that even on the most exposed surfaces some lotion will remain, wetting the films of pus adhering to those surfaces. These will continue to be a source of infection unless they can be sterilized. We have thus to consider the effect of antiseptics on them. In the case of the residue, there is a comparatively large quantity of antiseptic mixed with a small amount of pus, and for the purpose of estimating the effect of the antiseptics, I took it that the conditions of the following experiment were analogous.

Mixtures of one part of pus and nine of antiseptic were made, and, after ten minutes, 10 c.mm. planted in tubes of liquid agar at 42° C. After they were thoroughly shaken, the tubes were sloped and the agar allowed to set. They were then incubated at 37° C., and after a period were examined for colonies. It was found that when the antiseptic was strong the number of colonies could be counted readily. When it was weak, and in the case of the controls, the agar became opaque with innumerable minute colonies. The results were comparative, and did not lend themselves to strict quantitative expression. This was to be expected, for the specimens differed considerably. All were heavily but not equally infected. Some were thick and mucoid, and would not mix well with the antiseptics. However, in the case of every sample of pus, several antiseptics and a control were tested.

I give a few tables to illustrate the kind of result ob-

TABLE I.—Showing the Effects of Antiseptics upon the Growth of Bacteria in Pus.

Experiment I.

tained. Using this method, I came to the following conclusions: For the purpose of washing out a wound, neutral hypochlorous solutions are by far the most potent of the antiseptics usually employed, and are effective if diluted to 1 in 800 available chlorine, or 1 in 4 of the strengths usually dispensed. Mercury antiseptics 1 in 1,000, and carbolic acid 1 in 80, never sterilize completely, but kill a very large number of microbes, and delay the appearance of the growth of those which remain. Hydrogen peroxide by itself has very little bactericidal power, but when added to other antiseptics with which it is not incompatible, it increases their bactericidal power on pus organisms, presumably by its mechanical effect. Most of the other organisms in pus are killed more surely than streptococci and staphylococci, an action which is distinctly more marked in the case of mercury and carbolic

acid than in the case of iodine and hypochlorous solutions.

In the case of the film of pus which the mechanical disturbance of washing does not remove, we again have a large quantity of antiseptic acting for a comparatively short time. I considered here that the effect of the antiseptic could be judged by the following experiment: 20 c.mm. of pus were smeared on the surface of agar slopes and allowed to dry. The tubes were then filled with antiseptic lotion so that the films were completely covered. After an interval the antiseptic was poured away and the tubes incubated upside down, so that any excess drained away. The following table (II) illustrates the results:

TABLE II.—Showing the Effects of Antiseptics upon the Growth of Bacteria in dried Pus.

Experiment I.

Antiseptic.	Strength.	Time.	
Carbolic acid ...	1:80	9 min.	Growth as in control.
Eusol (1:200 available chlorine) ...	1:4	1½ min.	All but a few small areas sterilized.
" " ...	1:4	3 min.	All but a few small areas sterilized.
" " ...	1:4	5 min.	All but a few small areas sterilized.
" " ...	1:4	10 min.	All but one small area sterilized.
" " ...	1:8	2 min.	Two small sterile areas.
" " ...	1:8	5 min.	A few sterile areas.

Experiment II.

Carbolic acid ...	1:80	11 min.	Many discrete colonies all over film.
" " ...	1:80	40 min.	Sterile.
Iodine ...	1:1000	4 min.	Sterile.
Binioidide of mercury	1:1000	4 min.	Sterile.
Hydrogen peroxide	2.5 vol.	10 min.	Sterile.
Dakin's solution (1:200 available chlorine)	Undil.	1½ min.	All but a small area sterilized.
" " ...	"	10 min.	Sterile.
" " ...	1:2	5 min.	Two colonies.
" " ...	1:2	10 min.	Two colonies.
" " ...	1:4	5 min.	All but a few small areas sterile.
" " ...	1:4	10 min.	All but one small area sterile.
" " ...	1:8	10 min.	Good growth; part of film sterile.
Control ...			Massive growth.

The results are very similar to those of the first experiment. One point was clearly shown, that the thickness of film makes much difference to the efficacy of the antiseptic. It was clear also that some antiseptics were much more rapid in their action than others, notably the hypochlorous solutions. This suggests that these are the most suitable for the purpose of washing out a wound, especially as they have practically no effect on the activity of the leucocytes.

In the case of the dressings, the antiseptic is gradually diluted with pus, becoming at the same time less efficient. Here, therefore, the pus tends to be in excess. To test the effect of antiseptics in these circumstances, I took either a specimen of pus containing very few organisms, one or two per field of a film, or a very thick suspension of blood corpuscles in serum containing a few organisms, and added a proportion of antiseptic. A film was prepared from the mixture, which was then incubated. After a time another film was prepared and compared with the first. If no difference in the number of organisms before and after could be detected, I concluded that the growth was prevented by the antiseptic. If there was a difference, it is clear that the organisms grew in spite of the presence of the antiseptic. A mixture of pus and saline served as control. In the table (III) which I have set out, the strength of the antiseptics given is the ultimate strength in the mixtures. Thus a strength of binioidide of mercury 1 in 1,000 would be present in a mixture of four parts of pus and one part of 1 in 200 of the antiseptic. In these experiments I found it made very much difference whether phagocytosis had taken place or not, there being an advantage in favour of the antiseptic when

TABLE III.—Showing the Effects of Antiseptics upon the Growth of Bacteria when the Antiseptic is diluted with Pus.

Experiment I (4 parts of pus, 1 part of antiseptic).

* Subcultures on agar gave no growth.

† Subcultures on agar gave a little growth.

It had not—that is, organisms grew better (1) in pus from an infected wound than in sterile pus to which a suspension of microbes was added; (2) in the infected blood when it had been incubated so as to allow phagocytosis to take place. This would lead us to expect that antiseptic dressings would be especially useful (1) in the earlier stages of an infection, before there is much pus; (2) to prevent the growth of organisms which might obtain access to a wound during the dressing. The following are the conclusions which I consider these experiments justify: (1) The ultimate strength of the antiseptic being the same, the greater the proportion of pus the less the inhibition of growth. (2) Where pus is present in the proportion of 4 parts to 1 of antiseptic, organisms may grow freely when the following are the antiseptics used: Mercuric salts 1 in 200, carbolic acid 1 in 60, iodine 1 in 200, boracic acid 1 in 20, chloramine 1 in 20, hypochlorous solution 1 in 200 available chlorine. Organisms also grew when salt solution 20 per cent. was used. (3) Since organisms grow in pus in which antiseptics are present in the strengths indicated above, it is utterly unreasonable to expect any of them to diffuse into the tissues to such an extent as will give a strength sufficient to inhibit the growth of microbes, still less to kill them. (4) The pyogenic organisms are, as regard their growth in pus, among the least affected by the ordinary antiseptics.

The results obtained with hypochlorous solutions are of particular interest at present, inasmuch as eusol is being advocated for intravenous injection in cases of septicaemia. If they have any beneficial effect in the blood, it is clear the explanation cannot be found in direct bactericidal action.

When these experiments are reviewed as a whole, it becomes plain that in appraising the value of an antiseptic the purpose for which it is used must be taken into account. For instance, for washing out a wound, when the antiseptic would be in great excess, hypochlorous solutions are very potent, and carbolic acid comparatively weak. On the other hand, for an application in a dressing, when the pus would tend to be in excess, hypochlorous solutions are practically useless, whilst carbolic acid, although it has the disadvantage of interfering with the activity of the leucocytes, is fairly efficient.

Again, it becomes clear that, upon the evidence the experiments supply, antiseptics cannot do as much as is claimed for them. They certainly cannot sterilize the tissues subjacent to the surface of a wound, and, indeed, cannot be depended upon to sterilize an accessible surface, although they kill many of the organisms on it. Their use, therefore, depends on whether there is any advantage in this. It would seem that there is, for it can hardly be possible that the depth and intensity of the tissue infection are independent of the proportion and virulence of the organisms in the surface pus. If, therefore, these can be reduced, even temporarily, without at the same time unduly interfering with physiological processes, it is an important gain. This, which is in fact the most important object in dressing wounds, can be done by means of antiseptics, and herein lies their rôle in antiseptic

treatment. If we expect more from the antiseptics at present available, we shall be disappointed.

In conclusion, I would express my grateful acknowledgements to those with whom I have been associated under the auspices of the Army Medical Service, and of the Medical Research Committee; but in particular to my former chief, Colonel Sir Almroth Wright, although I have come to conclusions divergent from many of those at which he has arrived.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SEVERE CEREBRAL INJURY, ASSOCIATED WITH LAUGHTER.

On two occasions last summer I saw what I considered an unusual feature connected with the condition of two patients who were brought into an advanced dressing station suffering from severe head injuries. The injuries were in the lower occipital region of the skull, and were caused in one instance by shrapnel, in the other by high explosive. The shrapnel had caused a small fracture of the occipital bone, through which blood oozed, and the high explosive some bruising of the back of the head and neck. The men suffered from very severe shock and were quite unconscious of their surroundings, but exhibited the rather striking combination of a rambling and muttering delirium, associated with mild and frequent laughter.

There was here the suggestion of a continuous stimulation of the emotional centre for laughter, and as laughter is a modified form of respiration, an injury to some area near the respiratory centre in the floor of the fourth ventricle might account for the condition. The difficulty is that high explosive tends to spread its energies, and other centres of the brain may have suffered from concussion.

According to Sherrington (Schäfer's *Textbook of Physiology*) the respiratory apparatus is in the higher groups subservient to the emotional and mental expression, and he states that the bulb possesses inhibition to a great extent.

Nitrous oxide over-stimulates the respiratory centre and causes laughter, but, as in the case of chloroform and alcohol, the accepted opinion is that the preliminary excitement is due, not to stimulation of the brain areas, but to lessened activity of the functions of control and restraint. But a direct stimulation of the emotional centres is possible, and injury may reveal the truth where experimental work is impossible.

EARLY DIAGNOSIS OF WHOOPING-COUGH.

WITH reference to the memorandum from Dr. H. W. Jacob (April 22nd, p. 589), I would recommend him to have a blood count made in all suspected cases of whooping-cough. In all true cases of whooping-cough there will be found a marked lymphocytosis, and this is present some considerable time before the development of the characteristic cough. It is also helpful in the diagnosis of those cases in which the characteristic cough is absent or not heard. I am unfortunately not able to give any references to the literature on the subject.

J. F. CROMBIE, M.D., Major R.A.M.C.

British Expeditionary Force.

THE *Boston Medical and Surgical Journal* states that when the United States undertook the treatment of leprosy in the Philippines there were about 600 cases in the islands. The island of Cullion, which afforded excellent opportunities for agricultural work, was chosen as a place of segregation. Four hundred dwelling-houses, a theatre, a town hall, a school, and a harbour were built, and provided with a water supply and with sewerage and lighting systems. The colony now numbers about 3,500 lepers. They are given all possible liberty, organize their own police force, elect their own mayor and council, and take some care of the island. Attempts to interest them in cultivation of the land were indifferently successful, and a plan to induce them to take up cattle breeding—cattle being insusceptible of leprosy—is now under consideration. Treatment by chaulmoogra oil has given encouraging results; and already twenty-three lepers have been discharged as cured.

Reports of Societies.

THE BACTERIOLOGY OF CEREBRO-SPINAL FEVER.

At a meeting of the Pathological Section of the Royal Society of Medicine on May 2nd the President, Dr. F. W. ANDREWES, F.R.S., gave a short account of the bacteriological results in 11 consecutive cases of cerebro-spinal fever admitted to St. Bartholomew's Hospital during the first four months of 1916. Only one was a military case; of the civil cases, four were under the age of 4 years, and six were older children or adults. The type of coccus was determined in each case by agglutination with serums supplied from Millbank by Lieutenant-Colonel Gordon. The two earliest cases proved to be Gordon's Type 1, the remainder Type 2, except one case in an infant, which could not be referred to any known epidemic type. The pharynx was always examined, and the meningococcus was found in every case, twice in great abundance, sometimes only in small numbers. In each case the pharyngeal and spinal strains were compared by agglutination, and were invariably referable to identical types, indicating that the pharyngeal infection was an integral part of the disease. Most of the cases remained carriers for several weeks, one for more than seventy days. Treatment was by repeated lumbar puncture, with the new Lister Institute serum, prepared with numerous diverse strains isolated during last year's epidemic. The serum had been successful, for, though 4 cases out of 11 died (mortality 36.36 per cent.), 2 of these were infants under a year old and one a child of 3. Only one adult died, of streptococcal septicaemia following mastoid suppuration, after the meningococcal infection had been overcome. In cases over 4 years old the mortality was only 14.3 per cent. The improvement following the serum was in most cases immediate; in three severe cases, in which it was given on the second and third day, the patients were convalescent in forty-eight hours. One baby of 5 months recovered. Blood culture was carried out in three early cases. Twice it was negative, and once positive, the meningococcus being recovered from every tube. This case recovered promptly after serum was given (intravenously as well as intrathecally). In a fatal case the coccus was also recovered from the heart's blood after death.

A Transplantable Lipo-sarcoma in the Guinea-pig.

Dr. J. A. MURRAY exhibited microscopic preparations of the above. The original tumour appeared to be a lipoma; but its transplantability, and the more cellular structure it acquired, indicated a sarcomatous character, although it did not invade or produce metastasis. The author had not been able to raise a subgrowth from a simple lipoma. Some of the fat droplets in the cells were derived from the Altmann granules, which were abundantly present. The granules were present in the cells of malignant growths as well as in those of benign, although by particular methods of staining their presence in the former was not disclosed.

Specimens illustrating Toxic Hepatitis.

Dr. B. H. SPILSBURY exhibited specimens of livers obtained from patients engaged in doping and munition work, and who had died from the toxic effects of volatile poisons present in the materials used. In some recovery was in progress, considerable areas of the hepatic tissue having been regenerated, whilst the rest of it had become fibrotic after its destruction from fatty degeneration.

The Treatment of Wound Infections.

A communication upon this subject by Captain W. PARRY MORGAN is printed at p. 685.

Dr. D'ESTE EMERY said that he very much regretted that the lateness of the hour prevented his dealing adequately with Dr. Parry Morgan's paper, which teemed with controversial points, on many of which he was in strong disagreement with the author. As regards the first question, the power of hypertonic salt solution to cause the flow of a large quantity of lymph from a wound, Dr. Morgan appeared to object both to the idea that it was a process of osmosis and also to the simpler and non-committal

expression that the fluid was drawn out by the salt. The point was one that might properly be discussed before a physical society, but the important practical thing was that the application of a hypertonic solution to a sloughy wound the walls of which were teeming with organisms might determine a copious flow of what was, if not lymph, at least a fluid containing protein substances similar to those of lymph, and, what was of supreme value, containing defensive substances; so that after twenty-four or forty-eight hours no organism at all could be found in the secretion from the walls of the wound, though they might still be present in small numbers in cultures. Dr. Emery had a difficulty in following Dr. Parry Morgan's account of how this flow of fluid was brought about, and was not familiar with the cellular walls which he spoke about as existing in the walls of wounds. Further, if such occurred, he would have thought that if the tissues composing them were caused to shrink by the application of a strong hypertonic solution they would be narrowed and the outflow of fluid obstructed. Secondly, with regard to the formation of pus, Dr. Emery thought that the author somewhat misrepresented the views of the physiological school of treatment. The work of the leucocytes was done in passing through the infected tissues forming the walls of the wound. In their passage they ingested all the bacteria they could, and then passed on outward into the lumen, where they appeared as pus. This was in itself a bad thing, and must be got rid of by irrigation or drainage just as soon as possible, but it was an indication that the leucocytes were actively at work clearing out the bacteria from the tissues, and as such was a good sign. Whatever might be the technical difficulties in the way of investigation on this subject *in vitro* (and he thought they might be overcome), he pointed out that there was no doubt that in actual clinical practice the application of normal salt solution to the walls of a wound which had been treated with hypertonic salt solution did, as a matter of fact, determine such a flow of leucocytes to the surface. Dr. Parry Morgan appeared to agree with Sir Almroth Wright that salt in certain dilutions did stimulate the activity of the leucocytes, but did not think this was any advantage. Dr. Emery disagreed with this view, pointing out that the more rapidly the leucocytes travelled in the infected tissues the more quickly and thoroughly would they remove any bacteria which they encountered. On the third question, that of antiseptics, Dr. Emery agreed with the author that it was hopeless to expect them to diffuse any reasonable depth into the tissues in such amounts as to kill the organisms. He also pointed out that the author's views mainly applied to the parts at a fairly late stage when granulation tissue was present. At this stage, perhaps, not much harm was done by antiseptics, but the case was different in the early stages. At that time the walls of the wound were formed of bruised and damaged tissues, sometimes inches thick, which were so injured as to be on the borderland between life and death. A very small added injury might be sufficient to cause much greater loss of tissue than would be the case had all the conditions been made favourable, and any antiseptic, whatever its nature, which would kill bacteria would kill healthy tissues and, still more, damaged ones, even though it were more highly diluted. He thought, therefore, that the use of strong antiseptic lotions in the early stages of wound treatment might be a source of grave danger.

Professor S. G. SHATTOCK remarked that the weak part of the author's general conclusions in regard to the use of hypertonic salt solution was, it seemed to him, that he (the author) confined his attention too closely to what was taking place at the immediate surface. The condition of the parts in life differed from anything which could be reproduced *in vitro* in that in the former there was a continuous movement of lymph through the tissues as well as a partial escape at the wound surface. The construction of the wall of a granulating wound was more aptly represented in Sir Almroth Wright's second diffusion experiment, carried out with cotton-wool in a test tube of fluid, than by viewing the surface as sealed with a membrane strictly comparable to that of a dialyzer. An abstraction produced by hypertonic salt solution from the immediate surface, even though it were not of chemically normal lymph, would in life be followed by a physiological replacement of the bulk lost from the zone beyond, and the passage of this lymph through the infected district

would bring about an increased phagocytosis, and in this way help to clear up the deeper infection; a thing which antiseptics could not directly effect. One could not fail to see, nevertheless, that the use of antiseptics (all of which were chemical irritants) involved the production of a defensive angio-neurotic oedema—vascular dilatation followed by a plasmatic or serous exudation, which would aid in clearing the infection below the actual surface; and this factor presumably was one which also accompanied the use of hypertonic salt solution.

The Mechanical Causation of Appendicitis.

Professor S. G. SHATTOCK made a communication dealing with the above subject, based upon the critical examination of a series of appendicular concretions, and of the contents of 125 appendices in persons dying from various causes, 100 being over 40, and 25 between the ages of 15 and 25 years. Any such mechanical cause, if it was to account adequately for the alleged increase in appendicitis, would have to be (1) of recent introduction, and (2) of a kind which would extend to all classes of the community. One such that had been suggested was the ingestion of particles of the silica glaze detached from the enamelled hardware now in such general use. These particles were, of course, absolutely insoluble in the alimentary canal. The author had not found a single flake of enamel in any of the many concretions he had examined, nor in the contents of any of the 125 appendices studied.

In regard to the possible injury producible by the ingestion of silica in miners, Dr. Watkins-Pitchford, the present Director of the South African Institute for Medical Research, Johannesburg, had kindly obtained for him the following information:

"Dr. F. Aitken, the superintendent of the Miners' Phthisis Sanatorium, near Johannesburg, states that 537 cases of miners' phthisis have passed through this institution without his having seen a single case of appendicitis amongst them, nor has he noted any history of attacks before their admission. Dr. H. A. Loesser, the senior medical officer of the Crown Mines, has neither noticed nor heard it suggested that appendicitis is more common amongst miners than amongst others. The director of the Native Affairs Department states that in July, 1915, there were 210,247 natives employed on the works and mines of the Rand; appendicitis is so rare that deaths from this cause are not classed separately. He holds that mine natives are not at all liable to the disease."

The use of "French chalk" in dentifrices was another possibility; this material—magnesium silicate—being quite insoluble in the alimentary canal. The material was easily recognizable microscopically, but the author had never found any in the appendicular contents, or as forming the centre of any concretion.

The use of cerebos salt, which contains a notable amount of magnesium phosphate, could be ignored, since the latter was readily dissolved at 37° C. in a solution of HCl of the percentage in which the acid is present in the human gastric secretion.

The hypothesis of most promise was that put forward by Mr. W. H. Battle—namely, that a new factor in the causation of appendicitis had been furnished by the particles detached from the steel rollers now almost universally used in grinding wheat for flour. After a lengthy investigation the author had, somewhat reluctantly, come to the conclusion that no proof of the theory was forthcoming. He had traced the fate of steel filings in flour to which they had been purposely added, in bread made from such flour, and *in vitro* under the action of hydrochloric acid. Steel filings kept in flour did not undergo oxidation. When flour containing such was made into bread (by means of yeast), the particles become slightly tarnished from an extremely superficial formation of ferric oxide (rust). When these particles were extracted from the loaf and incubated at 37° C. in a solution of HCl of the gastric percentage, an abundant evolution of H took place; the fluid on being tested gave a ferrous (chloride) reaction only, without any ferric. This was explained by the fact that any ferric chloride produced from the trace of ferric oxide present was reduced to ferrous in the presence of the free hydrogen. The point of this was, that as ferrous chloride produced no constipating effects, no intestinal and appendicular stasis, favouring the forma-

tion of a concretion, could be attributed to the ingestion of steel particles, assuming this to take place. The amount of solution which steel underwent in the acid within two hours, at 37° C., was small; the metallic particles would, therefore, pass with little change, into the intestine; and here all further decomposition would be prevented by the action of the sodium carbonate of the pancreatic secretion, which rendered the intestinal contents alkaline. Steel filings might be kept for an indefinite period in a solution of sodium carbonate (of the percentage in which this is present in the pancreatic secretion) without undergoing any oxidation whatever.

Mr. Battle had cited the pigmentation of the appendix which he had come across in certain cases furnished by operation, as suggestive of the prolonged ingestion of steel derived from flour.

The author had critically examined nearly all of these specimens, microscopically and microchemically, with the following result: The coloration was due to the presence of somewhat translucent spherules of dull brown colour, contained in connective tissue cells lying in the lymphatic tissue which surrounds the crypts; there was none in the muscular wall. When the sections were heated, *secundum artem*, in HCl and potassium ferrocyanide or potassium ferricyanide, no ferric or ferrous reaction was obtained in the spherules; when sections were freely treated with pure HCl, no solution of the pigment took place. The pigment was clearly, therefore, iron-free, and it followed from this that it could not possibly be iron or iron oxide that had reached the lumen of the appendix and been translated into its walls.

The exact nature of the pigment was a more difficult question; in general characters it resembled iron-free blood pigment, and its presence was possibly due to the absorption of blood from the interior of the appendix; in cases of melæna the author had on several occasions found blood in its lumen.

Passing on to the study of a series of appendicular concretions: These were examined, after being incubated in dilute alcohol, by careful scraping whilst they were rotated beneath water, the whole procedure being conducted under a lens. The actual centre was examined microscopically *in toto* by removing it to a slide and crushing it in Farrant's medium. In certain cases appendicular concretions formed upon a foreign body, such as a pin or fruit seed. The presence of a nucleus, however, was not only unnecessary, but in the great majority of cases there was none. The most careful examination *ad hoc* demonstrated that there was no differentiated centre whatever. The common appendicular concretion, as told microscopically, consisted solely of undigested plant debris. Cellulose was digested only in the large intestine and by bacterial action alone; the debris referred to comprised free spirals; sclerenchymatous cells, the thick-walled stiff and sharply-pointed hairs from the pericarp of the oat and wheat (abundant in oatmeal and flour); disintegrating cells, wood, and bast fibre, etc. These consisted of lignine or cutine, and were incapable of digestion. The author had found no cellulose in the concretions; this excluded the possibility that the formation of such concretions resulted from a defective digestion of that substance.

The amount of calcareous deposition (calcium carbonate and calcium phosphate) occurring about the debris which formed the concretion was variable; in many examples it was of very limited extent, the concretions in the wet state being hardly firmer than clay. Such deposition was to be ascribed to bacterial action: the deposit, in fact, might not inappropriately be named "appendicular tartar." He had not yet met with a proper appendicular calculus. The concretions consisted chiefly or very largely of vegetable debris, and the most accurate name for them was that of "stercolith."

One factor that might conceivably lead to an increase in the formation of appendicular concretions, and so to an increase in appendicitis, was the recent rise of vegetarianism. A diet consisting almost solely of fruit and vegetable would furnish a greater abundance of indigestible residue. In some appendicular concretions there were conspicuous numbers of oat and wheat hairs, but the author had not come across a concretion composed solely of such, and corresponding with the oat hair concretions at times met with in the human colon. In the museum of the

College of Surgeons there were several specimens of these curious formations, the first identified having occurred in a Lancashire carpenter who was accustomed to take oatmeal daily in some or other form at every one of his meals.

The augmentation of intestinal debris, it was true, did not, *per se*, make for the formation of a concretion; it was necessary to assume an appendicular stasis, or a functional or physical irregularity of the appendix, as a second factor; for under normal circumstances free ingress and egress took place from and to the colon. The different causes that led to stasis in the colon would bring about the same condition in the appendix; and given a superabundance of indigestible residue, the latter would contribute a factor towards the production of a concretion. In fact there was no very abrupt line between concretions and scybala, and the actual centre of a laminar concretion was at times a small collection of minute scybala.

In regard to the results of the author's examination of the contents of 125 appendices from persons dying of other causes than appendicitis: the observations were made by pinning out the organ, slitting it up under water, and sweeping out the contents, which were then broken down with the brush, and carefully irrigated, any sedimentary residue being examined in Farrant's medium. For the present purpose it was enough to state that he had in no case discovered any particles of steel. He had selected for examination 100 appendices from individuals over 40 years of age, in order that ample time might have elapsed for the accumulation of metallic ingesta, and twenty-five from persons between 15 and 25 years, since this was the period of the highest incidence of appendicitis.

Incidentally, the author had encountered during these examinations two forms of neoplasm for the presence of which the patients had not been admitted. In one case many small pedunculated adenomata projected from the mucosa—of the kind which at times grew in large numbers from the colon. In the other case the appendix was the seat of a typical columnar-celled carcinoma, which was in process of ulceration, and had deeply invaded the muscular coat—an exact miniature of a carcinoma of the colon.

The general conclusion at which the author arrived, therefore, was that no evidence was forthcoming to show that appendicitis was due to damage inflicted on the mucosa by the prolonged ingestion of physical irritants; and that the appendicular concretions often associated with acute inflammation were not attributable to an accumulation of inorganic material which served as a nucleus for the subsequent deposition of faecal debris.

ANNUAL CONGRESS OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

The annual congress of the Ophthalmological Society of the United Kingdom was held on Thursday, Friday, and Saturday, May 4th, 5th, and 6th, under the presidency of Mr. WALTER H. JESSOP, in the rooms of the Royal Society of Medicine, the clinical meeting being held at the Central London Ophthalmic Hospital. There was a very good attendance of members, and more especially of those from the provinces. The great success of the congress was in large measure due to the indefatigable energy of the President, who in his opening remarks referred to the loss the society had sustained by the death of Professor Straub of Amsterdam, and Mr. George Coats, and read parts of letters from the following, regretting their unavoidable absence: Professor de Lapersonne of Paris, Professor Haab of Zurich, Dr. Landolt of Paris, Professor Gullstrand of Upsala, Drs. Storey and Maxwell of Dublin, Dr. Maitland Ramsay of Glasgow, and Dr. Edgar Browne of Liverpool.

Some Ophthalmic Lessons of the War.

The PRESIDENT, in his inaugural address, first referred to the results of injuries of the eyeball. He stated that during the American Civil War 41 cases of sympathetic ophthalmitis occurred amongst 254 cases of destruction of the eye; that the German official returns for the war of 1870 showed that 55.6 per cent. of all cases of injury to the eyeball were followed by sympathetic ophthalmitis, and that in more than half of these cases the second eye was involved within a year of the injury. During the

present war, owing to the excellent work of the ophthalmic surgeons in France and elsewhere, he had neither seen nor heard of a single case of sympathetic disease.

In dealing with the occurrence of papilloedema in relation with head injuries, the President said that, as he had already shown, it was often transient and disappeared without leaving any permanent residue; this, he believed, was in entire accordance with the views as to the pathology of papilloedema expressed by Leslie Paton and Gordon Holmes as a result of their excellent work.

In dealing with the retinitis which had occurred in a number of cases of trench nephritis, he expressed the opinion that it was purely toxæmic in origin, and that vascular changes were of no importance in its production. He looked upon the process as due to a severe retinal oedema, and referred to several cases under his care in which almost complete subsidence of the retinitis occurred with complete restoration of vision. The retinal changes might come on at a comparatively early date after the onset of nephritis.

Suitable reference was made to the excellent work of the French ophthalmic surgeons, Rochon-Duvigneaud and others, and the hope expressed that similar work would be done in this country. Mr. Jessop concluded by a short reference to the gravidic, diabetic, and tuberculous lesions of the eye, which he believed to be due to toxæmia.

Hereditary Optic Atrophy.

In an important paper on hereditary optic atrophy (Leber's disease), Mr. HERBERT FISHER brought forward evidence that it was dependent upon changes in the pituitary body. Having referred at length to the literature, he pointed out that in some cases the defects in the visual fields were remarkably symmetrical. He believed that this could not be explained as due to atrophy following the transient papilloedema which had been described in Leber's disease, and argued that the symmetry of the defects pointed strongly to direct implication of the visual pathways by a single lesion. He suggested that temporary disturbance of moderate degree of the pituitary body might be adequate to explain the phenomena of this disease. He drew a parallel between the signs and symptoms of Leber's disease and disease of the pituitary. Frontal headaches, vertigo, epileptiform attacks, and subjective visual phenomena were seen in both, as also a somewhat characteristically mild degree of papilloedema. The relation of the pituitary gland to the sexual organs was very close, as was seen in precocious or arrested development of these organs and impotence in pituitary disease, and the enlargement of the gland which occurred during pregnancy. So in Leber's disease there were two periods of onset—one at about the age of puberty, and a second period in women at the time of the menopause. The very close anatomical relation of the chiasma to the pituitary was insisted upon. Two children, the subjects of Leber's disease, were examined as to the existence of any abnormality in the sella turcica by means of *x* rays; in one no abnormality was found, but in the other unusual conditions were certainly present. This positive fact, taken with the considerations set out in the paper, led him to suspect that when an opportunity offered to some observer, it would be found that Leber's hereditary optic atrophy was primarily due to an inherited temporary disorder of the pituitary body.

The Retinal Circulation in Arterio-sclerosis.

Mr. FOSTER MOORE's paper dealt with the condition of circulation in the retinal arteries in cases of severe arterio-sclerosis. He argued that high pressure in the large arteries was the result of obstruction to the flow in the small vessels, and that therefore the pressure in the retinal arteries might be subnormal, whilst that in the brachial artery was 250 mm. Hg, or higher. The chief evidence in favour of this view was based on two series of observations: (1) That in some cases of arterio-sclerosis a very light pressure on the eyeball was sufficient to produce arterial pulsation, showing that the diastolic pressure in the retinal artery was but slightly above the intraocular pressure, which might be taken as 20 mm. Hg; (2) that whilst the intraocular pressure in arterio-sclerosis, as in health, varied directly with the local pressure in the vessels of the eye, yet it was not raised in arterio-sclerosis. Mr. Foster Moore believed that his observations on the eye were true of the brain and other tissues of the body, and

argued that vigorous measures carried out for lowering the blood pressure in such cases, were likely further to deplete the already curtailed blood supply to the tissues, and thus be harmful rather than beneficial.

(To be continued.)

Rebiefus.

THE HOUSING LEGISLATION MUDDLE.

ALLAN'S *Housing of the Working Classes*,¹ the fourth edition of which is just published, goes some way towards the elucidation of the law on a subject which has recently suffered five Acts of Parliament. The principal Act—the Housing of the Working Classes Act, 1890—was itself passed in order to consolidate some seventeen statutes, all enacted with the object of providing and improving the dwellings of the working and artizan classes. That Act was in its turn most imperfect, and was amended by several other Acts passed in 1894, 1900 and 1903, and by Part I of the Housing, Town Planning, etc., Act, 1909. The result is that the law has again become involved in much the same tangle as brought about the passing of the Consolidating Act of 1890. In this state of muddle the authors have conceived the happy idea of setting out the law as they conceive it to exist at the present time in the form of a Consolidating Bill annotated with reference to the Acts now in force. This, which forms Part III of the work, together with an admirable general summary of what the authors believe to be the law, should prove of considerable assistance to those who desire to acquire a general view of the confused jumble of enactments affecting this subject. Broadly speaking, the intention if not the effect of the Acts seems to be to empower local authorities to deal with large unhealthy areas by making them the subject of an improvement scheme; with small unhealthy areas, by making them the subject of an improvement scheme; to demolish houses unfit for habitation or obstructive buildings causing other houses to be unhealthy, and to erect dwelling and lodging houses for the working classes in districts where such dwelling houses or lodging houses are required. In the exercise of these powers the Acts provide that the local authorities shall act in accordance with the written representations of the M.O.H. or inspector of nuisances as the case may be, and to such officials the book should prove of service. To the ordinary medical practitioner, however, it will be of little utility.

As to whether legislation is any more wisely inspired in the United States of America than in this country we are not thoroughly informed, but we suspect not. Yet there can hardly be such an accumulation of badly constructed, narrow-visioned opportunist laws in the States, because, to judge by Dr. MacNutt's *Manual for Health Officers*,² the profession of the health officer has arisen in America during the last decade. His book contains the fundamental data required by such an official. The first hundred pages deal with the organization and powers of health authorities in the United States of America. The bulk of the volume is devoted to public health administration. Communicable diseases receive nearly two hundred pages, then follow chapters on child hygiene, milk, water, housing, nuisances, vital statistics, publicity, and other important matters. There are sixty pages of appendices. The book is comprehensive in its scope, and most of its contents are as applicable to the circumstances of this country as to those across the Atlantic. It is clearly written and covers a great deal of ground, and is packed with detailed information that should be of great service to medical officers of health as well as to all students who are making a serious study of the subject.

THE MEDICAL ANNUAL.

*The Medical Annual*³ for 1916 is the thirty-fourth annual issue. Naturally its contents are tinged a khaki tone in many sections; a special chapter is given to naval and military surgery, the great changes that have taken place recently in the treatment of wounds are adequately discussed, and there are many pages of interest dealing with the treatment and prevention of the many infections and other disorders to which soldiers are peculiarly liable. The first twenty pages of the volume give a review of progress in therapeutics during the year 1915. The bulk of the book—nearly 600 pages—is occupied by a dictionary of treatment, in which the medical and surgical progress for the year is recorded under the heading of the diseases for which each line of treatment is designed. Five-and-twenty pages follow in which a general review of naval and military surgery is given. Wound infections and their numberless new treatments are described in an excellent special article of twenty-six pages. At the end of the volume a quantity of important miscellaneous medico-legal and other information is given in a special section. The whole volume is excellently illustrated, and, like so many of the books issued by its publishers, it has a first-rate index. We conclude this brief notice by cordially recommending the new volume of *The Medical Annual* to the attention of all practitioners of medicine; they will find it good reading and an excellent investment.

NOTES ON BOOKS.

A GENERAL and popular discussion of the physiology of nutrition is supplied in pre-digested form by Mr. P. G. STILES'S little book on *Nutritional Physiology*.⁴ Prolonged study of the literature of the subject has convinced him of the difficulty of making any dogmatic and uncompromising statement about foods and feeding. Judgement must therefore be held in suspense. But as the reader is presumably acquainted with no more than the elements of physiological science, he has no special knowledge enabling him to balance the *pros* and *cons* bearing on the many debatable questions to which Mr. Stiles refers. Hence perusal of his book is not unlikely to arouse a feeling of insecurity and uncertainty on the one hand, and on the other a feeling of irritation at the inability of the writer to come down on either one side of the fence or the other. To say this, however, is not to criticize the patience and skill with which Mr. Stiles has selected his facts and arguments, nor to deprecate the nice poise of his judicial faculties.

One of the many causes that commonly lead to the writing of a book is the drifting of a square peg into a round hole. In the case of *A Dominic's Log*,⁵ the peg would seem to have been irregular and highly angular rather than square, the hole a berth as teacher in an elementary school under the Scottish Education Department. The book consists of eighteen chapters, in which the fictitious author discusses first and foremost himself, and secondly the rottenness of the society in which we live. Among the few prophets or authorities he can quote with approval are Ibsen, Shaw, and Wells. Apparently he would have us believe that he is a bold and bad young man, bosom friend of an actress in a musical comedy touring company, eager to swindle a railway company by travelling without a ticket on any possible occasion. A terrible fellow indeed! It is to be hoped that he will presently find a more congenial occupation than teaching, and some objects more agreeable to contemplate than his own personality and the sins of modern society.

For those who wish to teach themselves modern Greek the little book by Mr. ANASTASSION⁶ may be recommended. Starting with the alphabet, it takes the learner up to the point where he can travel and shop for himself. A phonetic pronunciation on Thimm's system is used throughout.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of the London and Counties Medical Protection Society, Ltd., was held at its offices, 32, Craven Street, Strand, W.C., on May 3rd. Dr. G. OWEN FOWLER, who was in the chair, referred to the loss the society had sustained through the death of Dr. Heron, one of its founders, treasurer and chairman of council down to 1913, and afterwards president. Few except members of the council knew how much work he did for the medical profession both in the society and otherwise. When reviewing the work of the society during the last year, the chairman said that the war had affected the society in two ways. In the first place, young men qualifying during the last eighteen months had immediately joined the army and had not realized the necessity of insuring; and, secondly, a number of members who had joined the army had retired from the society believing that it would no longer be able to help them. While appealing to members who joined the army not to leave the society, the chairman said it had been decided that those who had so resigned to take temporary military duty would be readmitted without the usual entrance fee, or as an alternative would be permitted to continue membership on paying up arrears. While the war had diminished somewhat the amount of litigation the administration of the Insurance Act was a source of frequent discussion between the contracting parties. The tendency of the Commissioners and Insurance Committees to usurp power over medical practitioners needed to be combated by such a society as the London and Counties, which would not be afraid of taking the matter, if necessary, to the House of Lords. The system of fining doctors in substantial sums for alleged faults was never contemplated by the Act, and required close watching. Clause 13 of the agreement should either be struck out or so amended that it could not be used as it was being used at present. The chairman continued as follows:

The idea of that clause is that we, as doctors, agree to reimburse the different local Insurance Committees in sums they may be out of pocket, or any expense they may have to incur, because the medical men were absent and had not left any locum tenens to do the work of the Insurance Committee. I say that is the idea of that clause, whereas the Commissioners are using that clause to inflict fines up to any amount—in one case even to the amount of £50—for something which they considered the doctor had not done which he should have done. I may say that the Insurance Committee that reported this case to the Commissioners themselves disagreed with the amount of the fine, and said it was out of all proportion. It is not generally understood, I think, that the clause does not say doctors may be fined for not doing anything they should have done, directly, but the Commissioners can abstain from paying the Insurance Committee any sum they like in respect of any doctor who they think should be fined, and the Insurance Committee has to get that amount back from the doctor. If something is not done with this Clause 13, I very strongly suggest that no doctor signs that agreement, when the next time comes on, without serious protest as far as that clause is concerned. One of the matters for which fines have been inflicted was for inaccurate certificates, yet in a large number of cases the Commissioners themselves insist on doctors signing untrue certificates. In the certificate of National Insurance, you have to certify that the patient you have examined is incapable of work. But the large majority of the cases you see are not incapable of work. They are unfit for work, or it is not advisable for them to go to work; still, they are perfectly capable of doing so if they will. There are cases in which a doctor has signed certificates, the patient coming every fourth night or so and getting his medicine, but still keeping at work. The doctor had said he was unfit, and when calling upon him for an explanation they said: "You have signed a certificate that the patient was incapable, and yet he did his work; so it is an untrue certificate." This was pointed out to the Commissioners at a meeting in November, 1914, and they promised it should be altered, but it still goes on. They fine a doctor for giving a wrong certificate, and yet they make them do this in 80 out of every 100 certificates. Look how widespread the working of the Insurance Act is becoming; look at the number of patients, young girls who are wishing to "do their bit," but whose parents are perfectly able to keep them, and who have comfortable homes. They are doing all kinds of Government work, and the Government insist that they shall be insured patients, so getting stamp money from them week by week, and taking away the doctor's private patients, giving them back again to him at so much per year. I saw in the paper the other day that a thousand Belgians living at Letchworth have been accepted as members of an approved society, and are now entitled to the ordinary benefits of the Insurance Act. The Act did not suggest that we should

attend all the people who come into the country, but doctors have to treat them at the rate the Government fix, and can any one say that that rate will not be the next hit of the Retrenchment Committee? With regard to fines on panel doctors, the Insurance Commissioners have inflicted a fine on a doctor of £10 for making a wrong diagnosis in a case of consumption. In this connexion the Insurance Committee reports that such fines in the case of panel doctors are generally excessive and disproportionate, and beyond what the justice of the case requires. What limit is there to this system of fines? The safety of the doctor becomes seriously imperilled if it is allowed to continue.

The Chairman went on to protest against the reduction of the notification fees, and criticized the action of the British Medical Association in suggesting that 1s. was an adequate fee in the case of measles. He suggested that the most dignified way for a medical man to deal with cases diagnosed as measles was to say to the parent or guardian, "This is probably a case of measles. Will you take the necessary steps?" and for the doctor himself to have nothing to do with the shilling fee. Dealing with the work of the society, he said that the financial position was stronger. The favourable balance in 1913 was £11,600, in 1914 £13,600, and in 1915 nearly £16,000. Investments had been written down by £974.

Resolutions adopting the report of the council and financial statement, electing Sir John Rose Bradford to be president of the society, and Mr. J. Herbert Parsons to be a member of council, and for the re-election of vice-presidents and members of council, and of the general secretary and financial secretary, were adopted.

INFANTILE MORTALITY AND THE RELATIVE VALUE OF MEASURES FOR ITS PREVENTION.

(Continued from p. 660.)

PRACTICAL VALUE OF MEASURES AGAINST INFANTILE MORTALITY.

IN his third Milroy Lecture before the Royal College of Physicians of London,¹ Dr. S. G. MOORE, M.O.H. Huddersfield, gave an account of the remarkable results in the preservation of infant life achieved at Villiers-le-Duc, a commune of the French Midi, by M. Morel de Villiers, who became mayor in 1884 and followed in the footsteps of his father, who had been mayor for some years before 1866. Dr. Moore gave a translation of a report made to the French Academy of Medicine, which confirmed the astonishing fact that the infant mortality in Villiers had been zero for ten years (1893-1903). The report embodied the text of the communal regulations. The preamble set out that it was the duty of the municipal authorities to endeavour to stop depopulation of the country by taking the measures necessary to prevent birth mortality and stillbirths and to do away with infantile mortality. Consequently the municipal council issued an order containing ten articles. The first provided that—

Every woman with child, whether married or not, having her home in the village, and not in possession of sufficient means to allow her to take upon herself the expense of the measures necessary to secure, as far as possible, not only her own life, but also that of the child about to be born, shall have the right to require the help of the village authority.

The second invites the woman to declare her condition, before the seventh month, at the office of the mayor, and state the midwife by whom she wishes to be attended. The midwife would then be instructed by the mayor to visit the woman and to ascertain that there was neither albuminuria nor dystocia, nor dangerous presentation. The third article provided that if the midwife then considered it necessary to call in a medical man she must at once notify the authority without giving the reason for the notice, and the authority then requests a medical man, chosen by the woman, to take the necessary measures. The fees of the medical man and of the midwife are paid out of a village fund for free medical aid, and do not involve any liability on the State or on the department; a grant of 10d. a day, paid to the woman if she stays in bed for six days, is drawn from the same fund. The fifth article required a woman who

¹ Published at length in the *Lancet* for May 6th.

takes in a child to nurse, if she does not feed it only at the breast, to provide herself with an apparatus to sterilize the milk. She can obtain the apparatus from the municipal authority at a low price, and poor mothers who nurse their own children can obtain the apparatus on loan. All infants placed out to nurse are weighed on the communal baby weighing machine every fortnight, and any illness in any nurse-child, especially diarrhoea, vomiting, or respiratory trouble, must be notified to the municipality within twenty-four hours. If a nurse fails to carry out these requirements her certificate may be withdrawn. The last regulation provided that every nurse bringing up her own child, or a child entrusted to her, whether at the breast or by bottle, who produces the child in good health at the age of one year shall be entitled to a grant of two francs a month, dating from the time when she began to nurse the child. An additional rule made later is that a midwife must call in a doctor if a confinement is not brought to an end within twenty-four hours. From statistics furnished by M. Morel de Villiers, it appeared that from 1804 to 1878 there were forty-three stillbirths, and only two from 1878 to 1903. The report to the Academy concludes as follows: "All the facts clearly impress upon us how necessary and essential it is to have the union, the combined strength of both the officials of the administration and the representatives of the medical profession. Isolated, their efforts, however good their intentions and wishes, will be fruitless and ineffective, but combined their efforts will be all-powerful. However, it is not always so, unfortunately."

In commenting upon the regulations, Dr. Moore enumerated what he considered to be their essential features. The first was that they are orders to the people concerned to do certain things, and not merely recommendations or advice.² The second point on which Dr. Moore laid stress was that every mother with child had the right to adequate assistance in child-bearing and was required to notify her pregnancy. Another point was that the midwives were required to ascertain that the pregnancy was normal; if it was not, they were required to notify the authority, which then paid a doctor chosen by the mother to take measures to bring about a satisfactory delivery. The regulations also provided for continuous supervision and provision for the infant by the authority. Dr. Moore observes that Villiers-le-Duc is a small place, that the life there is that of a simple rural village, that the numbers are small, and that the conditions in large urban communities are different. "When we remember," he continued, "that the infant mortality figure for the children of medical men is 40 in this country, it at once becomes manifest that there are factors in the problem which make it clear that the results at Villiers-le-Duc are not within our reach." Special attention ought, he considered, to be directed to the conclusion that success could only be obtained through the application of the combined strength of the officials of the administration and the representatives of the medical profession. Dr. Moore gave statistics of the progress of the notification of births in Huddersfield, and said that it had been the means of causing many more people to consult the doctor than was the case prior to its inception.

Incompleteness of Present Measures.

Dr. Moore observed that in this country the right of the mother to adequate assistance in childbirth had not been established. The resources of the Poor Law were not truly and willingly accorded as a right, but were yielded grudgingly and under degrading conditions. Neither midwives nor doctors had the duty explicitly laid upon them to ascertain that the pregnancy was normal, or, in the presence of abnormality, to notify the facts. He continued as follows:

² The regulations do not appear to us to bear this construction. As we read them, they lay it down that if a woman desires the help of the village authority she must fulfil the conditions of the several articles. The report was made by M. A. Pinard, Clinical Professor of Obstetrics in Paris, and is to be found in the *Bulletin de l'Académie de Médecine* (Paris, 15th, 1904). The words are "Le Conseil municipal . . . arrête . . . Toute femme . . . pourra demander l'assistance de la Commune." The initiative is with the woman, who is offered certain advantages if she complies with certain conditions. M. Morel de Villiers states that the countrywomen readily accept the conditions, for they understand their usefulness. Villiers-le-Duc is a village in the department of the Côte d'Or, with a population in 1804 of 447, and in 1903 of 230.

When the Huddersfield sanitary authority commenced to work in this field, it was suggested that provision need only be made for visits to the babies born in the poorer districts, but, after consideration, provision was made for visiting every baby born in the borough. The wisdom of this decision soon was justified. The assistant medical officers entrusted with the visitation of the mothers and babies immediately after birth were given a discretion. They were allowed to omit visits if they thought fit. (I may mention incidentally that they were instructed to behave exactly as they would in social life, not to enter a house—any house, however humble—without an invitation, not to seat themselves unless bidden to do so, and so forth.) Embarking on this work, they acted diffidently, as was natural. The result was that I received complaints, not that they had visited unduly or improperly, but asking: "Why was not my baby visited?" "How is it, since a visit was paid by the lady doctor to Mrs. —'s baby, that she did not visit mine?" I think it is plain that assistance in these matters should be tendered to all, without distinction, and where it is declined it should not be pressed. Provided, of course, that there is reason to believe that the mother is really furnished with adequate assistance in her need.

Notification of Pregnancy.

He had recently been able to establish a system for the voluntary notification of pregnancy in Huddersfield, and when a pathological condition was found in the mother she was urged to call in a doctor. With regard to objections to the notification of pregnancy, he said:

I have heard the statement—in fact, it was made by a personage holding "high office"—that the notification of pregnancy is not to be thought of; that it would violate the privacy of family life and interfere with one of the holiest functions of humanity. With all respect, I affirm that only absence of information, nothing but lack of insight, can permit any one to entertain such views. I have heard of objections from the professional point of view. But objection from this source can only be based on misconception. In every case, so far as Huddersfield is concerned at least, every condition calling for medical treatment will be referred to the family doctor.

It may be and probably will be claimed, and it certainly ought to be the case that the claim might be made with strict propriety, that where a woman has engaged the services of a duly qualified medical practitioner, she does not need any further help. I cannot speak to-day with any definite opinion, but some years ago I know that it was not the practice of the family doctor, when engaged for a confinement, to make any systematic precise effort to satisfy himself that his patient was normal, and that none of the conditions which from time to time arise and which are so disastrous in their results are present. If it be the case that things are altered nowadays, and that the family doctor does exercise these precautionary functions, then manifestly his patients are not in need of any further assistance; but if the old-fashioned state of affairs persists—and the death returns appear to indicate that this is in fact the case—then, in my judgement, the medical practitioner may very well welcome such aid as can be rendered by a colleague whose function and duty it is to do so, it always being well understood that every case should be referred for treatment to the medical man of the woman's choice.

In concluding his lecture, Dr. Moore urged that the following things should be done at once:

"Require the universal notification of pregnancy. Secure for every mother adequate provision of the means necessary for a satisfactory termination of her pregnancy. Make provision for and require the supervision of every infant born. Prohibit fraudulent advertisements which destroy infants. Provide proper education."

THE Columbia University has received an anonymous gift of £2,000 to be used for purposes of surgical research.

THROUGH the generosity of Mrs. Almeric Paget, the Miller General Hospital for South-East London in Greenwich Road has been able to extend its massage and electrical departments. Mrs. Paget has provided six masseuses to attend at the hospital daily, and two or more to attend in their own homes patients who, in the opinion of the medical officer, are not fit to go to the hospital. Mrs. Paget is also equipping the hospital with radiant heat baths, high frequency and other electrical appliances, and with gymnastic apparatus.

EDUCATION AND THE NEGLECT OF SCIENCE.

THE developments of the war must be bringing home to everybody the importance of theoretical and applied science for the welfare of nations nowadays. What else is it but science that will bring victory to the Allies in the present state of Europe? What else is it but science that has enabled the Central Powers to hold on so long to the initial advantage they gained by going to war prepared? It is theoretical science, using the term in the widest sense, that dictates the means of war, discovers the explosives, devises the special steels used for all small arms, guns, and howitzers, invents and calibrates the range-finders, outlines provisions for the health of the armies engaged, and makes the thousand and one preliminary observations upon which the practical success of armies in the field from day to day depends. It is applied science in all its branches—the work of the chemist, the electrician, the expert mechanic, the metallurgist, the mechanical engineer, the exponent of applied mathematics, the surgeon and the physician, the sanitary officer—to mention but a few out of many scientifically trained experts—that places the possibility of victory on land and sea and sky in our hands. One may say so much without in the least belittling the work of our gallant soldiers in the trenches. It is they who do the fighting and give their lives for King and country. It is they who fill the foreground in the great battle-piece of the present war of German aggression. But behind them in the middle distance stand all the munition workers and operatives of the engineering shops, trained in applied science, working by micrometer and gauge and not by rule of thumb, and owing no small share of their efficiency to the calculated scientific design of the machinery they handle. And in the background of this great picture, above the battle yet in some sort ordering its progress, may be discerned the men of science whose wonderful inventions—the high explosive, the machine gun, the internal-combustion engine, the aeroplane, the airship—have rendered possible the hell-on-earth in which our armies are weltering. Granted that the position is ethically deplorable—that increase of knowledge should be applied to the increase of destruction of human life and the products of human labour—yet it is only a part of the abomination of war for which there is in ethics no defence, save to the followers of Bernhardt. But even so there are in this same background of the picture those other men of science, above the battle but in some sort ordering its progress, who by the knowledge they win through the applied science called research enable the soldier to protect himself against disease, to preserve himself to fight for his cause, and to make sure that if he must give up life and health it shall be owing to the acts of the enemy and after doing his part to win the final victory.

Quite apart from their importance in the conduct of war, theoretical and applied science are indispensable for the progress of the arts of peace, commerce.

and industry. Medical men who have found their supplies of drugs made in Germany cut off will be the first to realize the practical bearing of this fact. To workers in every department of science which has any bearing on practical affairs—and which science has not?—this has long been a platitude; there is now reason to hope that the truth is gaining general recognition and acceptance. Once it is recognized, the importance of giving an elementary training in science to all persons who are receiving any formal education at all will be accepted as a necessary corollary. We shall not then find members of the Government stating in good faith, and unchallenged, that it has recently been discovered that glycerin can be prepared from fatty substances, a fact proved by the great chemist Scheele as long ago as the year 1779, and familiar to every soapmaker since.

Most valuable work in bringing forward the claim of science to occupy a prominent place in all schemes of general education is now being done by "The Committee on Neglect of Science," a voluntary committee of scientific men who have the best interests of our empire at heart. Reference was made to its activities in the *BRITISH MEDICAL JOURNAL* of February 5th last (page 209). On May 3rd this committee held a meeting in Burlington House at which four resolutions aiming at the advancement of the teaching of elementary science were put forward. These resolutions were temperately worded, and may be taken to stand for the minimum demands to be made on our Government and educational authorities. They may be summarized as follows: The first resolution laid down the generalization that it is a matter of national urgency that the natural sciences should be made an integral part of the educational course in all the great schools of this country, and should form part of the entrance examination of the universities of Oxford and Cambridge, as well as of the newer universities.

The second and third resolutions really contain the gist of the whole matter and touch the vital spot. They affirmed that it is in the highest degree desirable that the Government should exercise the large power it possesses of encouraging the study of the natural sciences and thereby increasing the efficiency of our public servants, first by assigning capital importance to the natural sciences in the competitive examinations for the Home and Indian Civil Service, and secondly by requiring some knowledge of the natural sciences from all candidates for admission to Sandhurst. Remembering the large part played by scientific appliances and scientific methods in modern warfare, it is astonishing that this last request should still have to be made. As the matter is urgent and time is required to develop action, it should be at once taken in hand by the Government. The important point here is this, that the lead must come from above. The public schools cannot fairly be asked to strike out a line of their own and set the ball in motion by pushing the teaching of science; they have to teach the subjects asked for by the universities, the army, and the public services, where natural science is at a discount. In the same way the universities cannot be urged to strike the first blow for science; they have to consider the schedules of the chief examinations that university men have to face outside their universities, and here natural science goes for so little as to be worth almost nothing. The cure for this vicious state of affairs lies in the hands of His Majesty's Government and nowhere else; and so the fourth resolution very rightly instructed the committee to take such steps as it might consider appropriate to bring these views to the notice of the Government.

We wish the movement a full measure of success. The time is ripe, and more than ripe, for the reconsideration of the schedules of the civil service and other important public examinations. The object of such examinations is to detect and encourage ability in the candidates. Ability has been defined as the power to deal successfully with an unknown problem; an able man has been described as a person who does more than is expected of him. As Dr. Alexander Scott pointed out in his recent presidential address to the members of the Chemical Society, in the civil service examinations at the present time everything of a nature to test a man's ability to tackle an unknown problem, however simple its nature, is carefully excluded by cautiously worded syllabuses, which detail the range of the facts and the nature of the tests which may be applied. We are far from underestimating the difficulties that lie before those who have to make the public realize the importance of natural science and research as instruments of education, as well as of progress among the comity of nations in the world of to-day. But Dr. Scott's criticism of elaborate examination schedules is undeniably sound, and as well worthy of consideration as it must be familiar to our educational authorities. We bring it forward here because it bears upon the main endeavour of the Committee on Neglect of Science, which is to get the Government to help on the teaching of natural science by beginning to work, like charity, at home. The universities must follow the Government; they cannot, we fear, lead the way. The public schools must follow the universities.

THE HOUSING OF A VIRILE RACE.

DR. WALDO, who is coroner for Southwark as well as for the City of London, was, before he held his present offices, medical officer of health for the former borough. One of his last acts in that capacity was to present to the then (1900) newly-constituted borough council a report in which he urged the demolition by the London County Council, under the provisions of the Housing of the Working Classes Act, of certain houses and streets in the Tabard Street area of Southwark, on the ground that they were unfit for human habitation. As long ago as 1889 he had reported on a serious outbreak of typhus fever which originated in Tabard Street and spread to other parts of Bermondsey and Newington. It does not appear that any effective action has been taken either by the borough council, the London County Council, or the Local Government Board. As coroner he has held two inquests recently in each of which the jury appended a rider to its verdict expressing the opinion that the houses in which the deceased persons had lived were in an insanitary condition and totally unfit for human habitation. The coroner, in addressing the jury, said that the rooms condemned were small and unwholesome, and he thought it incomprehensible that the London County Council permitted such hovels—not fit for a dog or a donkey—to be relet. In one of the cases (that of a woman aged 53) the Poor Law medical officer who attended her had stated in evidence that it was necessary to hold up an umbrella in all parts of the room except the corner in which he found the woman lying dead. The rain had flooded the floor, and what remained of the wall-paper was lying in strips owing to the damp. In another case—a boy named Albert Martin, aged 9—death took place in a garret 8 ft. square and 6 ft. 6 in. high. In it the boy, the boy's mother, and three other children had lived. As these statements were

made in open court by an officer of the Crown, they must, we presume, be accepted as correct, and they do not seem to have been denied by the authorities, although each shows itself concerned to shift the responsibility. The excuse of the London County Council is that the premises are not in its possession, and that the control of insanitary property is primarily vested in the local health authority—the borough council; but the borough council denies this, and the President of the Local Government Board stated in the House of Commons the other day that he had recently made an Order empowering the London County Council to proceed forthwith with the demolition of the worst houses in the area.

As so often happens, there seems to be difficulty in fixing responsibility for the delay in removing this plague spot, but the fact that such conditions should have been allowed to persist for a quarter of a century within sight of the palace of Westminster, where laws are made, and of Whitehall, where the administration of these laws is controlled, more than justifies the grave reproaches addressed to us by the Prime Minister of Australia within the last few months. In the speech he delivered after receiving, just across the river from Southwark, the freedom of the city of London on April 18th, he said that if we are to keep this empire as a heritage for the British race "we must create conditions under which the population of both these islands and the Dominions will rapidly increase and multiply. And as mere numbers avail nothing, we must create an environment which will breed a virile and resourceful people. Wealth will not save us, if our crop of such men fail. Lacking men, Rome and the mighty empires of the ancients fell, and the dust of ages covers their proud monuments. The defence of our empire rests ultimately upon the basis of a national policy in Britain herself, as well as in the Dominions overseas, that will organize and develop our tremendous resources, that will promote the welfare of the agricultural and manufacturing industries, and ensure to the great masses of the people those opportunities of employment, those conditions and remuneration of labour, and that standard of comfort which are the just heritage of a civilized people, and lacking which the British race will dwindle and degenerate, and our mighty empire crumble to decay. We must see to it, therefore, that from one end of this great empire to the other the gates of opportunity shall be slammed in no man's face. There must be a chance for every one."

What sort of chance would the boy Albert Martin have had living in a room 8 ft. square with his mother and his three brothers and sisters? What sort of ventilation was there in the room at night? What sort of place had he to play in by day, so that he might have the exercise every child instinctively desires? How much money was left to buy food for the five people after paying the rent of the 8 ft. square room? What sort of chance are the three other children having to-day? What sort of chance are the other family parties in the Tabard Street area having to make their contribution to "a virile and resourceful people"?

It is this kind of thing which is making a great many people ask themselves whether much of the public health legislation of the last decade has not been mere tinkering. How much is really to be expected from infant and mothers' welfare centres, tuberculosis clinics, and other legislative and administrative schemes, however well meant, when parents and children have to return to 8 ft. square rooms with no ventilation to speak of, but with leaking roofs?

There is clear evidence that such schemes when well administered are capable of doing good, and Dr. Moore in his recent Milroy lectures—an abstract of which has been published in our issues of last week and this week—shows that attention wisely directed to the care of the mother during pregnancy and at childbirth, and of the infant during the first year of life, is capable of achieving quite remarkable results in favourable circumstances. But is it reasonable to expect that such measures will produce much effect where the home conditions are so bad as in the condemned area in Southwark?

The whole history of housing legislation in this country is a monument of legislative ineptitude and administrative failure. In 1890 an attempt was made to consolidate in the Housing of the Working Classes Act some seventeen statutes enacted at various times to provide or improve dwellings for the working classes. At once the weary task of amending it had to be begun, and other Acts were passed in 1894, in 1900, in 1903, and in 1909, but in spite of all we have the Tabard Street area and a good many other areas not much better in London and other towns.

THE STANDARD OF VISION IN THE ARMY.

THERE has been considerable uncertainty as to the exact standard of vision demanded by the War Office for soldiers. This uncertainty has led to many men being rejected who are suitable for some form of service, and to many being passed into the army with visual defects which render them useless on active service. Men who have seen service in the trenches have, after their return home, been found to have such poor vision that they were not only valueless as fighting men, but actually a source of danger to their comrades. As examples we may cite cases of advanced congenital familial night blindness, congenital nystagmus, myopia of over 10 dioptries, and hypermetropia of 8 dioptries. On the other hand, we know of the case of a man who had $\frac{3}{8}$ vision in his right eye but a blind left eye who was rejected repeatedly for the R.A.M.C., although in civil life he was an efficient high railway official; and of a medical man who was recently rejected because he had slight myopia perfectly corrected by glasses. Every ophthalmic surgeon is aware of these facts. The visual standards seem apt to vary with the examiner. Probably little attention has been given to the very important question of the illumination of the types. Poor lighting may reduce the acuity very considerably, and a candidate with, say, $\frac{1}{8}$ vision might easily be rejected by an examiner who had no adequate arrangements for illuminating his types. In the presence of such confusion it may be useful to summarize the regulations in force at the present time. They are as follows: (a) If a recruit has an acuity of $\frac{1}{2}$, or better, with each eye without glasses, he is to be considered "fit"; (b) if his acuity is $\frac{3}{8}$ with the right eye and not less than $\frac{1}{8}$ with the left eye without glasses, he is "fit"; (c) if he can see $\frac{1}{2}$ with the left eye and not less than $\frac{3}{8}$ with the right eye, he is "fit" for the A.S.C., the R.A.M.C., the A.O.C., and drivers of the R.A. and R.E. These regulations apply to general service in the field. A later regulation says that: A man is fit for garrison service at home or abroad if he can see well enough to shoot with the aid of glasses. This regulation is ambiguous, for it does not state the acuity necessary for shooting. We presume, however, that if $\frac{1}{2}$ is enough for active service without glasses, $\frac{1}{2}$ with glasses will be sufficient for garrison duty. We would, however, again impress upon those who examine recruits that it is absolutely essential that the test types be well illuminated and placed at six metres (20 ft.) from the candidate. If the room be too small, a set of types graduated for five metres should be employed.

THE NOTIFICATION OF INFECTIOUS DISEASES AND TUBERCULOSIS.

THE annual report on public health and medical subjects, furnished by its medical officer to the Local Government Board, presents, for the fifth year in succession, full statistics of the incidence of notifiable infectious diseases in each sanitary district in England and Wales. These tables, prepared under the supervision of Dr. Arthur Newsholme, not only supply information with regard to numbers, but enable the reader to trace the actual local incidence of any of the scheduled diseases, and to ascertain the rate of such incidence per 1,000 of the population. The occurrence of local outbreaks or the relative immunity of any one town or district during the year can thus be discovered and examined with equal ease. Thus, in the case of cerebro-spinal fever, which would appear to have been very much more frequent during the last twelve months, it may be noted that whereas the larger proportion of the cases could be located in only nine districts, still the general incidence of the disease was very widespread. Acute poliomyelitis, on the other hand, showed no increase, although the cases were, in like manner, very widely distributed. Of these two diseases, it is interesting to note that cerebro-spinal fever appeared much more frequently during the months of March and April than at any other time, while poliomyelitis occurred far more often during the autumnal months. The incidence of pulmonary and other forms of tuberculosis would appear from the published figures to have diminished progressively during the last few years, but it is pointed out that there may have been a good deal of duplication, so that the true value of the figures given is uncertain. It is obvious that the freedom from tuberculous disease of any town or district cannot be accurately gauged from the number of cases notified in any one year. It is by no means unlikely to happen that in one year there may be hardly any new cases to record, while a considerable number of previously notified cases are still resident in the locality, their disease steadily increasing and with it the danger of infection, slight as it is, to those who may be associated with them. The presence or absence of acute infectious diseases may be fairly estimated from notification statistics, but such statistics may be wholly misleading in the case of tuberculosis.

THE VOLUNTARY RESTRICTION OF BIRTHS.

IN the Lower House of Convocation at York last week an interim report of the Committee on Moral Corruption and Social Life was discussed. It dealt with the decline of the birth-rate, and suggested the appointment of a Government Commission. Canon Lambert of Hull alleged that the clergy did not sufficiently recognize that this was not simply a social question for the State, but had a moral and spiritual side with which the clergy were at much more liberty to deal. This home thrust was countered by Canon Rountree of Manchester, who made an attack upon medical men. "I cannot help feeling," he said, "that not only do they not use their influence in correction of the evil, but that very often they are offenders in the matter of encouraging artificial restriction." The Dean of Carlisle characterized this as a very serious charge, and asked Canon Rountree for facts. The medical profession, the Dean said, had always exercised enormous influence, and if it were believed in the country they were encouraging these practices it would be a terrible thing. Canon Rountree does not appear to have attempted to produce any facts, and, so far as we know, he will have difficulty in finding them. We are quite aware that there are a certain number of members of the medical profession who have been bitten with the notion that over-population is the root of most of our social evils, and that they have formed a society which has been in existence for a good many years without commanding any appreciable measure of professional support. It is, of course, possible that Canon

Rountree has come across some member of this medical sect, but if this be the only ground for his charge then he is committing the very common, but none the less very pernicious, fallacy of arguing from the particular to the general.

SUPPRESSION OF QUACKERY BY THE GERMAN ARMY.

It appears that in Germany the quack has attracted the unsympathetic attention of the military authorities. Indeed, if the measures directed against him are as effective in practice as they appear on paper, there is every prospect of his being dragooned out of existence by the provident Prussian. In some military districts unqualified practitioners are totally prohibited from advertising, and they are forbidden to print "puffs" of methods of treatment, apparatus, and tonic and prophylactic remedies. In other military districts the unqualified practitioner is no longer allowed to treat venereal disease, nor to advertise as a specialist in diseases of the skin and abdomen, under which heading he has in the past caught many a patient suffering from venereal disease. The advertisements of abortifacients and conceptional preventives, thinly veiled under such headings as "Discreet advice," "Advice for women," etc., have also been suppressed. Even the anti-vaccinationist has not eluded the "verboten" list, for the publication and distribution of treatises, handbills, and other vehicles of agitation against prophylactic inoculations in the army are forbidden. We have already referred to Hindenburg's drastic regulations against venereal disease. So far no uniform system has been adopted throughout Germany, and each military area seems to have independent regulations. Indeed, in some commands no active measures have been adopted. But on the whole the suppression of quackery by the military authorities during the war seems to have proved very effective, and the hope is expressed¹ that the prohibition of quackery, which has proved so successful in war time, will be continued in a modified form after the war.

ELECTRICAL METHODS IN SURGERY.

In a lecture at the Royal Institution on May 5th Sir James Mackenzie Davidson contrived to bring within an hour's survey the various respects in which electrical science is proving to be the handmaid of war surgery. Chief among the electrical methods, of course, was that of *x* rays, and the lecturer showed very skillfully, by means of experiment, at once the value of the skiagraph and its possible fallacies. He exhibited two *x*-ray pictures of exactly the same subject, but taken with the tube in slightly different positions, with the result that in one case a bullet appeared to be lodged in the right lung, and in the other in the left. The single *x*-ray photograph, he said, however realistic it might appear, was not like an ordinary photograph, from which the relative positions of objects could be inferred with some accuracy; it was a shadow-picture, and therefore might be very misleading. To obviate the fallacies, he recommended the stereoscopic method, which, however, was still inadequate for exact localization, which required some system based on precise measurements, such as the cross-thread method. The lecturer also showed that electrical means were available, not only to ascertain the position of the bullet in the body, but to guide its extraction. Of these methods he instanced the telephone attachment, by means of which a click or rattle was communicated to the receiver whenever the surgical instrument touched the foreign body—the telephone forceps, with *x*-ray screen in combination, and also the Bergonié electro-magnet. He concluded with a tribute to that shadow army—from ambulance worker to surgeon-general—who followed the movements of the combatants with the same precision and

assiduity as the shadow, in some experiments he had been showing his audience, had followed every change in the position of the lamp.

APPARENT DEATH AND PREMATURE BURIAL IN INFANTS.

From time to time ghoulish novelists and writers of short stories make the flesh of their readers creep by describing premature burials. Even musicians have attempted to do the same thing in another medium, as a well-known prelude by Rachmaninoff gives witness. Professor Baculo of Naples, after describing¹ one of the not uncommon cases in which an infant, after apparent death, comes to life again for a longer or shorter period, gives details of an apparatus he has devised to prevent the possibility of burial during life. His patient, a child 2 months old, with diffuse bronchiolitis, to all appearances died suddenly after the administration of several litres of oxygen to counteract the asphyxial attacks from which it suffered. Respiration and the action of the heart both stopped; but half an hour later rhythmical movements of the jaw, lips, and alae nasi were observed. The heart began to beat again, slowly at first, and respiration began once more, jerky at first, presently of the Cheyne-Stokes type. Consciousness was recovered and the infant took the bottle again, but four hours later died in an attack of asphyxia. This time death was real and not merely apparent. Professor Baculo goes on to a general discussion of the phenomenon of apparent death in infants. Death, he says, is a process, not a sudden event, and is indistinguishable at first from a merely temporary suspension of life. This is particularly true of the sudden deaths of infants, attributed in various cases to such causes as hypertrophy of the thymus, enlarged mediastinal glands, disease of the parathyroids, acute diseases of the lungs or stomach or nervous system, foreign bodies in the air passages, congenital defects of the heart or brain, fits, and diseases of the kidneys, suprarenal glands, or skin. He describes a number of the physical signs or tests that have been proposed to distinguish between true and apparent death. Bouchut, for example, remarked that after death the retinal arteries empty, the fundus oculi turns leaden grey, and, most certain sign of all, the optic disc becomes invisible. Icard advised the subcutaneous injection of fluorescein solution twenty minutes, and again twenty hours, after apparent death; when, if the patient still lives, the conjunctiva turns yellow and the skin turns green. To wait for such certain signs of death as decomposition of the tissues and the formation of bullae on the skin is not always convenient; nor is the employment of mortuary chapels in which the body rests for at least twenty hours before burial. Professor Baculo observes that after death the lungs are in a state of forced expiration. His apparatus for the detection of apparent death and the prevention of the premature burial of infants is quite simple. It consists of a cradle in which the body is laid for twenty-four hours after apparent death; a lever is pivoted on one side of this, with a vertical arm descending to rest on the ensiform cartilage at one end, while the other end of the lever is arranged to make an electrical contact and ring a bell should it move downwards. If the infant is alive it will presently breathe, and if it breathes, the sternum will rise with inspiration and cause the bell to be rung. Professor Baculo argues that some such apparatus should always be available in public institutions for children.

ILLUMINATION PROBLEMS.

THE present time, when so much attention is being devoted to the promotion of scientific and industrial research, has seemed to the Illuminating Engineering Society opportune for resuming the work of its Special Committee on Research which, under the chairmanship of

¹ *Therap. Monatshefte*, January, 1916. (Reported in *Norsk Magazin for Lægevidenskaben*, April, 1916.)

¹ *Giorn. Internaz. d. Sci. med.*, Naples, 1915, xxxvii, 525.

Professor Silvanus Thompson, was appointed just before the outbreak of war, and at the meeting of the society on May 9th it presented an interim report which was mainly concerned with a survey of the many problems which await attention. Priority is to be given to investigations relating to the development of lamps and lighting appliances. The subject of glare is also to be studied together with the limits of permissible intrinsic brilliancy, on which a suggestive report has been issued by a similar committee in the United States. The British committee is also setting itself to deal with the comparative effect on vision of natural and artificial illumination and of various systems of artificial lighting from the point of view of fatigue. An important matter, often discussed but never authoritatively settled, is the standardization of the so-called artificial daylight—that is, the various forms of artificial light used in conjunction with special devices to imitate the colour of natural light. An attempt is now to be made to arrange the chief artificial illuminants in the order of their resemblance to daylight. At present there is no universally accepted standard of white light, nor any generally accepted standard white surface. It is thought that street lighting after the war will be a good field for effort, particularly as regards more scientific treatment in the shading of lamps and the distribution of light. The conception of a minimum illumination desirable in the interests of safety is to be encouraged. Among some general suggestions for work which is to occupy the committee is the lighting of hospital wards, which at present is often unsatisfactory. There is also room for investigation in the lighting of operating tables. The subject has also to be studied in connexion with field hospitals using portable lamps. The committee, which includes one medical member, Dr. James Kerr, is certainly to be congratulated upon the comprehensiveness of its programme.

A MEETING was held at the Royal Army Medical College, Grosvenor Road, S.W., on May 10th, to consider the advisability of establishing benevolent societies for the benefit of the widows and orphans of officers, non-commissioned officers, and men of the Royal Army Medical Corps of the Special Reserve the Territorial Force and the new armies. After some preliminary discussion, it was resolved to adjourn until some date next month, which will be duly announced, when it is hoped that a considerable number of officers of each branch may attend and give expression to their views.

Medical Notes in Parliament.

Compulsory Service.

THE bill "to make further provision with respect to military service during the present war," the Committee stage of which was begun in the House of Commons on May 9th, contains fourteen clauses. The first extends and continues the operations of the Military Service Act, 1916. It provides that every male British subject who has at any time since August 14th, 1915, or for the time being is, ordinarily resident in Great Britain, and who has attained the age of 18 and has not attained the age of 41 years, shall be deemed as from the appointed date to be duly enlisted in His Majesty's Regular Forces for general service with the colours, or in the reserve for the period of the war, and to have been forthwith transferred to the reserve. The clause does not apply to a man who has attained the age of 41 before the appointed date. Nor does it apply to men who come within the exceptions set out in the first schedule to the Military Service Act, 1916, as maintained by the bill. The exceptions include men ordinarily resident in the Dominions or resident in Great Britain for the purpose of education or some other special purpose; men in holy orders or regular ministers of any religious denomination; men who have been discharged from the naval and military services in consequence of disablement

or ill health. The second clause extends the period of service in the Territorial and Reserve Forces for the duration of the war. Clause 3 provides that a man who has offered himself for enlistment and been rejected since August 14th, 1915, may be called upon unless the Army Council is satisfied that he need not again present himself for medical examination and sends him notice to that effect. Clause 4 deals with certificates of exemption, and provides *inter alia* that a certificate of exemption may be granted subject to the condition that it shall not be renewable except on application made with the leave of the tribunal. Clause 5 amends Section 3(3) of the principal Act, by providing that a man who has not obtained a renewal of his certificate shall be deemed to have been enlisted and transferred to the reserve within two weeks instead of two months after the expiration of the certificate. Clause 6 deals with proof of offences in connexion with deserters and absentees. Clause 7 with the production of certificates of exemption, and Clause 8 with the issue of notices. Clauses 9, 10, 11, 12, 13 and 14, are as follows:

9. *Transfer to Reserve under Special Circumstances.*—The Army Council may make arrangements, to take effect during the continuance of the present war, for the transfer to the Reserve of any member of the regular forces, or for the temporary demobilization of any member of the Territorial Force, notwithstanding anything in any Act or in the terms of his enlistment, in cases where the transfer or demobilization appears expedient in the general interests of the country and the Army Council are satisfied that it can be effected under conditions which will render the man transferred or demobilized immediately available for service in the case of military necessity.

10. *Amendment of the Army (Transfers) Act, 1915.*—The first proviso to Section 1 of the Army (Transfers) Act, 1915 (which provides for the maintenance of the rate of pay of a soldier transferred to a corps not of the same arm or branch of the service as the corps in which he was serving), shall not have effect except in cases in which the Army Council direct that that proviso shall apply.

11. *Transfer of Officers and Men of the Territorial Force.*—(1) During the present war, notwithstanding anything in Section 7 of the Territorial and Reserve Forces Act, 1907, the orders and regulations for the government and discipline of the Territorial Force made under that section—

(a) May authorize a man of the Territorial Force when belonging to one corps to be transferred without his consent to another corps, and may authorize a man of the Territorial Force to be posted without his consent to a battalion or other body of the regular forces included in the corps to which he belongs or is transferred; and

(b) In the case of an officer or man in the Territorial Force who is liable to service outside the United Kingdom may, for the purposes of such service and notwithstanding anything in any instrument defining the conditions of such service, authorize the drafting of any such officer or man to any unit of the Territorial Force within the corps to which he belongs or to which he may be transferred;

and those orders and regulations may also provide for the maintenance of the rate of pay of a man who is transferred without his consent to a different arm or branch of the service in cases in which it appears desirable to the Army Council that the rate of pay should be so maintained.

(2) This section shall affect officers or men of the Territorial Force notwithstanding that they were commissioned, enlisted, or re-engaged before the date of any order or regulation under this section.

12. *Power to Form Corps for More than One County.*—During the continuance of the present war Section 9 of the Territorial and Reserve Forces Act, 1907, shall be construed as authorizing corps to be formed for more than one county.

13. *Provision as to Liability of Territorials to Serve Outside the United Kingdom.*—Where an officer or man of the Territorial Force has, before or after the passing of this Act, accepted liability to serve in any place out of the United Kingdom, that liability shall continue, notwithstanding anything in the conditions of service, during the continuance of the present war, unless the competent military authority as defined for the purposes of Part II of the Army Act otherwise direct.

14. *Short Title.*—This Act may be cited as the Military Service Act, 1916 (Session 2), and the principal Act and this Act may be cited together as the Military Service Acts, 1916, and the Territorial and Reserve Forces Act, 1907, and this Act (so far as they relate to the Territorial Force) may be cited together as the Territorial Force Acts, 1907 and 1916.

The House has not made much progress with the bill; a discussion on the exclusion of Ireland occupied much time. Subsequently a number of amendments to the words in the first clause as to age were proposed. The first proposed to substitute for the specified ages (18 to 41) the expression "military age" and to leave the term military age to be defined from time to time by the King in Council. This was negatived without a division, and an amendment to lower the age to 17 in place of 18 was defeated by 213 to 52. An amendment to exempt a youth

who, being under the age of 19, has been certified by the War Office to be undergoing sufficient training for the purpose of becoming an officer in His Majesty's army, was withdrawn after Mr. Long had agreed that if necessary words should be added to the bill to meet the point. An amendment to provide that no man should be sent to serve abroad until he reached the age of 19 was rejected on a division by 134 to 46, after Mr. Long had recalled the assurance given on behalf of the Government that it was not the policy of the War Office to send men of this age abroad.

In a written reply, on May 9th, to a question by Mr. Perkins, Mr. Tennant said that Territorial officers and men of military age now serving at home who had not undertaken the imperial service obligation would come under the provisions of the bill.

War.

Soldier's Heart.—On May 4th Mr. J. M. Henderson asked whether a very large number of men of the Expeditionary Force were in hospitals suffering from what was called trench heart, but which was the result of excessive cigarette and tobacco smoking; and, whether, seeing that the number of cases was increasing, the matter would be inquired into with a view of remedying the evil. Mr. Tennant replied that a certain number of cases of disordered action of the heart, or so-called soldier's heart, were being investigated in a hospital specially set aside for the purpose. There was no evidence that the number of cases was increasing at present. By some observers this condition was attributed to excessive cigarette and tobacco smoking, and this was being looked into by skilled experts.

British Prisoners in Germany.—On May 8th Lord Robert Cecil said that the question of the separate publication of reports made by officers in the Royal Army Medical Corps who had returned from Germany would be considered. He agreed that the reports of men who had actually lived in the camps must be more reliable and important than those of a casual visitor. The Government Committee had been set up on purpose to consider all such reports and get a true account of the condition of the prisoners.

Medical Examination of Soldiers and Recruits.—In reply to Mr. Ashley, who asked whether all men were medically examined at the time they joined the second-line Territorial units to ascertain if they were fit for military service, Mr. Tennant said that all men were medically examined on enlistment, and also as soon as possible after joining their units. Supplementary questions showed that there was a belief that a large number of men quite unfit for military service were retained in the second-line units, and Mr. Tennant undertook to have another medical examination made if he was furnished with particulars of cases. In reply to Mr. Hogge, on May 8th, Mr. Tennant said that under the new bill it was not proposed to re-examine men who rightfully held a recognized certificate which showed that they were not fit for any form of military service. He could not say that Army Form B 2505 A would in all cases be accepted, because it was conceivable that a man might be fit for some form of military service, but not fit for general service.

Continued Treatment after Discharge from Hospital.—Major Hamilton has asked whether men found medically unfit after return from the front could be posted to the Army Reserve, or, in the case of Territorial units, demobilized, so that they could return to their home comforts for a few months while receiving massage or other medical attention by attending daily the nearest military hospital. Mr. Tennant, in a written answer, stated that from a medical point of view the proposal was not advisable. The men were much more likely to get fit to return to duty if, on discharge from hospital, they were treated in command dépôts, where they had the advantage of medical treatment and graduated exercises under proper control.

Army Dispensers.—In reply to Mr. Tyson Wilson, who asked a question as to the number of qualified chemists in the army whose services were not being used to the best advantage, Mr. Tennant said on May 3rd that all medical units at home and abroad were fully supplied with dispensers. He added that if any qualified chemists serving in combatant units made application to be transferred to the R.A.M.C., the case of each applicant would be considered as vacancies for employment arose.

Vaccination.—In reply to a question by Mr. Snowden as to men who had been refused leave because they objected to vaccination, and as to whether this "violation of the rights of the men" would be stopped, Mr. Tennant said that no officer or man had any right to leave. Leave was given to those whom the commanding officer considered deserved it. If a man refused to be vaccinated, which he was within his right in

doing, it was within the discretion of the commanding officer to grant or withhold the privilege of leave.

Insanitary Dwellings.—On May 3rd Mr. W. Thorne asked the President of the Local Government Board (1) whether he was aware of the verdict of the jury at the Southwark Coroner's Court, at an inquest held on April 4th on Margaret Young, aged 53, who was living in the Tabard Street condemned insanitary area; if he was aware that the jury stated that in their opinion the house in which the deceased woman lived and died was in an insanitary condition and totally unfit for human habitation; if he would urge upon the responsible sanitary authority or authorities, without further delay, to take steps to close the premises in question; and (2) if his attention had been called to the inquest on Albert Martin, aged 9 years, at the Southwark Coroner's Court on April 11th, 1916, in which Dr. Spilsbury and the local medical practitioners stated that the infectious fever and lung disease which caused the boy's death was more than likely to spread if it got a footing in an overcrowded district such as the condemned Tabard Street area; if he was aware that the rooms condemned—small ones—were barely furnished and farmed out singly at a rental of 6s. per week; that the coroner stated that it entirely failed his comprehension how such hovels, not fit for a dog or a donkey, came to be re-let; and if he intended taking any action in the matter. Mr. Hayes Fisher, who answered, said that the coroner had supplied particulars to the President of the Local Government Board, who was in communication with the London County Council on the subject. It was the duty of every local authority, under Section 17 of the Housing, Town Planning, etc., Act, 1909, to make a closing order in respect of any dwelling house which was in a state so dangerous or injurious to health as to be unfit for human habitation, and the President had no doubt that steps which might be necessary in this direction would be put in hand by one or other of the local authorities concerned. A copy of the question and of the reply was being sent to the local authorities—namely, the Southwark Borough Council and the London County Council; but as, in the event of closing orders being made, there was an appeal to the Local Government Board, its President could not do more than this.

Royal Commission on Venereal Diseases.—On May 3rd the Prime Minister repeated the information given to the deputation from the National Council for Combating Venereal Diseases by the President of the Local Government Board to the effect that 75 per cent. of the cost of carrying out the recommendations of the Royal Commission as to diagnosis and treatment should be defrayed by a grant from the Exchequer. Mr. Asquith added that he could not at the moment promise legislation on the other recommendations of the Commissioners, some of which raised very controversial questions, but the whole matter was receiving the earnest attention of the President of the Local Government Board.

"Summer Time."—The resolution in favour of an alteration of clock time during the summer months was adopted on May 8th by an almost unanimous vote—Ayes 170, Noes 2. The resolution is: "That, in view especially of the economy in fuel and its transport that would be effected by shortening the hours of artificial lighting, this House would welcome a measure for the advancement of clock time by one hour during the summer months of this year." The Home Secretary said that, though the change could have been brought about by an Order in Council, since it was a war measure, it was thought desirable to ask the House to adopt a bill to make the change for the period of the war. The bill, entitled a bill "to provide for the local time in Great Britain and Ireland being in advance of Greenwich and Dublin mean time respectively during the summer months," was introduced on May 9th.

THE New York Medical Record states that operations for sterilization were performed recently on ten male inmates of the Wisconsin State Home for the Feeble-minded, Chippewa Falls. Their ages ranged from 15 to 30 years. These are the first operations of the kind done under the new Wisconsin law.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

(From a Special Correspondent in Northern France.)

TROPICAL DISEASES.

THE great bulk of natives of India disappeared from France shortly before the publication of the King's farewell message to the Indian troops. They were never really as numerous as people thought. It was their dress that made them seemingly ubiquitous. It attracted attention to them wherever they went. No doubt was ever felt as to their fighting qualities, but there was a good deal of surmise in medical quarters as to how their new environment would affect them; also, when the first cold wet weather after their arrival began, there was among the general public a disposition to commiserate as well as admire them. It was assumed that they must be suffering much more than other troops.

As a matter of fact, a great many of the men who aroused these feelings were born and bred in hill districts of Upper India, where the winters are quite as cold and wet as even was the weather of 1914-15 over here. But of such saving clauses the sentimental soul takes no count. He thinks of a man of colour as of one to whom anything but warmth and sunshine must be both strange and unbearable. It must be admitted, too, that for ideas of this order a casual visitor to the Indian hospitals was likely to find some support on a cursory glance at the bed boards, but, according to I.M.S. officers of long experience, they were quite mistaken.

The troops from certain parts of India suffered very considerably from illnesses of a domestic order, such as mumps, but the total amount of sickness was held to be not at all greater than it would have been among the same troops had they been campaigning in India, and the mortality from disorders commonly associated with cold and wet was quite moderate. It was also pointed out that the chief wastage from disease was among men of the camp follower class and in certain regiments that had been brought up to full strength somewhat hurriedly. The more representative fighting troops of India had resisted the climatic conditions of Europe with great success.

Some I.M.S. officers, in fact, went so far as to prophesy that when percentage returns for all troops alike became available, it would be found that the figures for native regiments were better than those for the British troops which had formed part of the Indian contingent. The native troops, it was said, had, relatively speaking, been better clothed and better fed.

Be all this as it may, there was one account on which the departure of the native troops diminished anxieties. It lessened the probability of the outbreak of any disease of tropical origin among the troops as a whole. It did not end it, for there is always the chance of tropical disease being imported by white troops moved back from the East; as also the possibility of certain epizootic diseases communicable to man being introduced in packing cases and returned stores.

Meanwhile it is highly satisfactory to be able to say that so far the British forces as a whole have been practically free from any of the diseases commonly regarded as tropical in their origin. Considering that the anopheles mosquito is to be found in Flanders, and that there were sources from which it might become infected, it would not have been remarkable if there had been a good deal of malarial fever. But this was not the case. A definite diagnosis of malarial fever in men who had not lived in the tropics or subtropics was established in quite a small number of cases, and they were all of a benign type.

There were also reported from time to time a certain number of cases which were written down as dysentery, but clinically they appear to have been of a very mild type, and according to a pathologist who investigated a good many of them, they were almost all of bacillary origin. Of anything in the nature of an outbreak of amoebic or true tropical dysentery, the writer heard of only one example, and this was amongst French troops.

This happy condition of affairs last summer and autumn is not to be ascribed to good luck, but to the care that the

medical authorities took to reduce the chances of disease importation to a minimum.

As soon as it was decided, in the autumn of 1914, to bring over Indian troops, the D.G.M.S. directed the medical officer in charge of the southern lines of communication to make arrangements for the careful examination of all Indian troops on their arrival, and to detain in isolation at various camps all men suspected to be suffering from disease of a communicable kind. The writer saw these arrangements in operation last spring (1915), and was much impressed by their completeness. The cases detained and isolated included a good many examples of recurrent fever and one or two of very early anaesthetic leprosy.

SCIENTIFIC MEETINGS.

Meetings of medical men for the purpose of discussing subjects of professional interest have long since ceased to be uncommon occurrences in the war zone in France, but are not always of identical type. Most of them are the outcome of the formation of regular medical societies, but a good many are invitation meetings organized by the officers of some particular hospital.

There is also considerable difference in the method of procedure. At some the proceedings are on all-fours with those of ordinary medical societies at home, a discussion being initiated by the reading of a formal paper. At others the aim is usually of quite a different character; it is not to promote a contrasting of views and theories, but to elicit an interchange of observations in regard to some problem considered to be more or less new to all present. Consequently the reading of formal papers is not encouraged, and the experiences recorded are impersonal; they are supposed to be those of the institutions to which the speakers belong rather than of the speakers themselves.

This latter system was introduced by the officers of the Australian Hospital; who at the meetings that they periodically organize take great pains to secure the presence of representatives of all classes of medical units likely to have acquired any knowledge of the matter under consideration. The object, of course, is to get light thrown upon it from as many points of view as possible. Both plans have their advantages.

Of the three or four formally organized societies, pride of place in respect of seniority belongs to the medical society which was formed about the end of 1914, while the youngest is that known as "The Third Corps Medical Society." The latter started work about a year ago, and it so happens that both owe their existence to the energies of the same officer.

Nearly all those who take part in the work of the Third Corps Medical Society are either battalion medical officers or members of the staffs of field ambulances, and it holds its meetings in a building situated at a spot within three miles or so of the fire trenches. This place was chosen because the connecting roads happen to render it easily accessible to formations serving a comparatively wide section of the front.

The subjects so far discussed have been the treatment of abdominal wounds; gas attacks and smoke helmets; trench feet; the sanitary arrangements of front line units; pediculosis and baths; cerebro-spinal meningitis; and the treatment of wounds suitable for work in the trenches, at regimental aid posts, and at field ambulance dressing stations.

It is to be hoped that this society will not long remain the youngest of the group, for a front line medical society which holds its meetings at an accessible spot and leads an active existence is bound to be of much utility, as from a professional point of view front line officers lead a somewhat isolated existence, and have few opportunities of hearing what their fellows are doing in regard to the problems by which they all alike are faced.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

MAJOR FRANK CHARLES PEREIRA, Madras Medical Service, died in the General Hospital, Madras, on April 9th, aged 53. He was born on April 28th, 1862, took the Scottish triple qualification in 1886, and entered the Indian Medical Service as surgeon on March 31st, 1888, becoming

major on March 31st, 1900, and lieutenant-colonel on March 31st, 1908. He had been for many years in civil employment in the Madras Presidency, but at the beginning of the war reverted to military duty, and was recently stationed at Quetta, whence he returned sick to Madras two months before his death. He served on the north-east frontier of India in the Lushai campaign of 1889, receiving the medal with a clasp.

Captain Robert Donald, R.A.M.C.(T.F.), died at his residence in Chelsea, on May 3rd, aged 55. He was educated at the University of Glasgow and at Anderson's College, Glasgow, and took the Scottish triple qualification in 1884. After filling the post of medical officer of health of Unst, he settled in practice in Chelsea, where he was medical officer to the Royal Engineers and War Office employees. He joined the 1st City of London Brigade, Royal Field Artillery, as lieutenant and medical officer on July 28th, 1911, becoming captain on January 27th, 1915.

Assistant Surgeon Edmund Carey Hallums, Indian Subordinate Medical Department, reported to have died on active service abroad, was born on September 22nd, 1892, and became fourth class assistant surgeon on November 21st, 1913. Prior to the war he was stationed at Ranikhet.

Killed in Action.

Lieutenant A. Booth, R.A.M.C., was reported as killed in action in the casualty list published on May 8th. He took the degrees of M.B., B.Ch.Oxon. in 1912, obtained a temporary commission on November 15th, 1915, and was attached to the King's Own Scottish Borderers.

Wounded.

Major P. Sampson, D.S.O., R.A.M.C.

Captain G. F. Denning, R.A.M.C.(T.F.), (Dublin).

Captain J. T. McCullagh, R.A.M.C., temporary. (Dublin). (This name was at first erroneously given as Captain W. McK. H. McCullagh.)

Captain R. W. Murphy, R.A.M.C., temporary.

Captain H. G. Wilson, R.A.M.C., temporary.

Lieutenant N. C. Kapur, I.M.S.

Lieutenant A. Massey, R.A.M.C., temporary.

Lieutenant H. L. Mooney, R.A.M.C., Special Reserve (Dublin).

Assistant Surgeon E. H. L. Shaw, I.S.M.D.

Missing.

Lieutenant J. Brown, R.A.M.C., temporary.

DEATH OF SON OF MEDICAL MAN.

Cyril Niccoll Searancke, Lieutenant R.N., second son of Dr. N. F. Niccoll Searancke, of Mitcheldean, Gloucestershire, killed in the loss of H.M.S. *Russell*, on April 27th, aged 28.

NOTES.

FROM recent reports about the Liverpool Merchants' Mobile Hospital it would appear that it is doing most excellent work. The Liverpool Exchange Newsroom subscriptions now exceed £700, and letters appear from time to time in the local press from soldiers testifying to the benefits they have derived through the munificence of the Liverpool merchants.

HONOURS.

A supplement to the *London Gazette*, dated May 5th, 1916, gives the names of a number of officers as mentioned for good service in the Gallipoli peninsula, supplementary to Sir Ian Hamilton's dispatch of December 11th. Among them are a large number of medical officers, whose names were given in the *BRITISH MEDICAL JOURNAL* of May 6th, as the recipients of various decorations.

BRIGHTON HOSPITAL FOR PATIENTS WHO HAVE LOST LIMBS.

Lieutenant-Colonel J. N. MacLeod, C.I.E., I.M.S., writes: In your note in the issue of May 6th on "The Brighton Hospital for patients who have lost their limbs," your statement as to the command of the late hospital for Indians in the same building is incorrect. I was in command of the general hospital for wounded Indian soldiers in the Dome and Pavilion, Brighton. The officer you mentioned was S.M.O. for the combined hospitals at the York Place School and the Pavilion.

THE GERMAN ARMY MEDICAL SERVICES.

The Deutsche Gesellschaft für Chirurgie held its annual meeting in 1915 in Brussels. We gather from a recent note in the *Times* that it has met this year in Warsaw, and that, as was the case last year, the opening address was given by Professor v. Schjerning, the head of the German Army Medical Service.

According to our contemporary, he stated that 24,000 doctors were in the service of the army—three-quarters of them in the field and one-quarter at home. There were 3,000 doctors working with the Red Cross, 400 dentists, 1,800 chemists, and 92,000 men in the medical services. The voluntary nursing service employed 72,000 persons in Germany and 22,000 on the lines of communication. There were 238 hospital trains taking wounded and sick back to Germany from the hospitals near the front. There were 26 large steam laundries on the lines of communication, and on the frontier there were 18 large disinfection establishments, dealing with 100,000 men a day.

Ireland.

MEDICAL WORK IN DUBLIN DURING THE REBELLION.

THE Sinn Fein rebellion has come to an end after a week of horror in Dublin, leaving all the city hospitals filled with seriously wounded cases, both military and civilian. Altogether about 180 were brought to the hospitals either dead or dying, and this number would have been greater only that after the first few days many of the hospitals had to refuse to allow any further number of dead to be brought, as they had no room for them.

In answer to a question on May 9th the Prime Minister gave the following statistics of the casualties sustained by the troops, the Royal Irish Constabulary, and other forces during the outbreak:

	Killed.	Wounded.	Missing.	Total.
Army officers	17	46	—	63
Other ranks	86	311	9	406
Royal Irish Constabulary ...	12	23	—	35
Dublin Metropolitan Police ...	3	3	—	6
Royal Navy	1	2	—	3
Loyal Volunteers	5	3	—	8
Total	124	388	9	521

There is no means of estimating how many of the Sinn Feiners were wounded or killed as very few of them were brought to the hospitals, and many must have met their death in the parts of the city that were burnt. The number of civilians reported as dead in the hospitals is 160, and it is probable that a certain proportion of these were Sinn Feiners, but there is no doubt that a large number of harmless civilians were both wounded and killed during the firing that took place in the streets. Many were hit through their own fault because they ventured into dangerous areas, but a certain number were undoubtedly injured while following their ordinary business.

Some of the first casualties which occurred on Easter Monday were brought to the Royal City of Dublin Hospital; and on Wednesday afternoon, when the serious fighting took place close to the hospital between the military who were arriving from Kingstown and the rebels, 68 cases were admitted to the hospital between 4 and 10 p.m. These were nearly all soldiers who were wounded or killed within one or two hundred yards of the hospital; later on during the same evening the scene of fighting shifted nearer the city, and the cases were brought into Sir Patrick Dun's Hospital, chiefly by the nurses, who several times went out under fire to bring in the wounded. The Richmond Hospital was seized by the rebels on Easter Monday, and three of the visiting staff who were in the hospital at the time had to remain for the whole week; the rebels brought their wounded to this hospital to be dressed and then removed them to the Four Courts, which they had partly converted into a hospital for themselves. The Red Cross and St. John Ambulance did splendid work, and organized in a few hours temporary hospitals in Merrion Square and the neighbourhood, where many cases were treated; in this way overcrowding of the general hospitals was prevented. Jervis Street Hospital, which was in the worst area, close to the Post Office, treated about 400 cases during the week, but many of these were of a minor character, over 80 being cases of looters who had received cuts from broken glass.

Owing to the fact that the wounded were in most cases brought to the hospitals within a very short time of being

wounded—often within half an hour or less—the results obtained were remarkably good, and undoubtedly many cases were saved which would have died had the circumstances been other. For instance, a man was brought into the Royal City of Dublin Hospital on Tuesday morning (April 25th), within half an hour of being shot in the back; the bullet had emerged under the right costal margin. He was immediately taken to the theatre and the abdomen opened; the right lobe of the liver was so extensively torn that it was impossible to suture it, but by packing both the torn cavity and all around the haemorrhage was checked, and the patient is now recovering. A few other abdominal cases were operated on, but so far as can be learnt without success, as in every case the damage done was extensive, the wounds being transverse or caused by soft-nosed bullets or ricochets.

The ammunition used by the rebels was of all kinds, from the modern nickel-covered rifle bullets to large soft lead bullets "with the point cut off, and even 12-bore cartridges filled with buck-shot and slugs." Some of the wounds inflicted on the military were in consequence very severe, specially those traversing the chest and head. At the Royal City of Dublin Hospital all the cases were washed with eusol, and extensive wounds were left open and packed with gauze wet with eusol, the surrounding skin being in all cases painted with tincture of iodine. This treatment appears to have been most successful, even the most extensive wounds in nearly all cases healing without severe sepsis.

The following communiqué was issued by General Sir John Maxwell on May 7th:

I desire to express my sincere appreciation of the services rendered during the recent disturbances in Dublin by the medical, surgical, and nursing staffs of many of the city hospitals, and in particular of the gallantry shown by those nurses who exposed themselves to a heavy fire in attending to and removing the wounded.

Also to the members of the Red Cross and St. John Ambulance Societies and the many medical men and private individuals who gave assistance in attending to the wounded, or placed their houses at the disposal of the military for use as dressing stations. In numerous instances these services were rendered at considerable personal risk, and under circumstances reflecting the greatest credit on those engaged in them.

J. G. MAXWELL,

General Commanding-in-Chief the Forces in Ireland.

Scotland.

TWENTY-FOUR new students have joined the Edinburgh School of Medicine for Women this summer; the number of women now attending the school is about 167 (entries not complete). At Queen Margaret College, Glasgow, the number of new women students in medicine is 20, compared with 10 a year ago. This brings the total number of women students in the medical faculty up to 207.

At a public meeting in Bothwell on May 3rd it was resolved to raise a fund of £1,000, with the object of erecting a suitable memorial to the late Dr. W. G. Macpherson, whose death from pneumonia on March 31st was recorded in the JOURNAL of April 15th. Dr. Macpherson's sterling qualities as a man and as a physician had earned him a large circle of friends and patients in the Lower Ward of Lanarkshire. He was active also in work for the profession; he was a loyal member of the British Medical Association, and at the time of his death a member of its Scottish Committee.

ANNUAL MEETING OF THE EDINBURGH ROYAL MATERNITY HOSPITAL.

Dr. Freeland Barbour, President of the Royal College of Physicians of Edinburgh, who presided over a large gathering of the directors, staff, and supporters of the Edinburgh Royal Maternity Hospital on May 8th, 1916, referred to the loss the hospital and the community had sustained in the death of Sir Alexander Simpson, and spoke of the great work which during thirty-five years Sir Alexander had achieved in and for the hospital. He congratulated the directors on the fact that the number of in-patients during the year 1915 was the highest on record, and mentioned also that the number of undergraduates and of nurses trained in connexion with the institution had

both increased, from 51 (1914) to 87 (1915) in the case of the former, and from 53 (1914) to 61 (1915) in the case of the latter. The finances of the hospital were also satisfactory, and a small addition had been made to the reserve fund. He alluded with satisfaction to the establishment of a Central Midwives Board for Scotland, with Sir Halliday Croom, one of the hospital staff, as its chairman, and to the further development of the prematernity work, a department in which the hospital had led the way, and to which another member of the staff (Dr. Ballantyne) had greatly contributed. The chairman then moved the adoption of the annual report. The motion was seconded by Mrs. Leslie Mackenzie, who strongly advocated the necessity for caring for the health of the school child, not only when at school, but during the pre-school age, and also before birth through the mothers. The Rev. Norman Maclean, in moving a vote of thanks to the directors, medical staff, and Ladies' Committee, took occasion to name several of the greatest men the world had ever seen who all might well (if they came into life at this time) have been born in a maternity hospital. Sir Ludovic Grant moved a vote of thanks to the chairman.

England and Wales.

LANCASHIRE HEALTH REPORT.

THE report of the medical officer of health for the administrative county of Lancashire for the quarter ending March 31st shows that the death-rate corresponded to 13.2 per 1,000 of the estimated population, which was 1,666,488. The principal epidemic diseases, excluding diarrhoea, caused 264 deaths, or a rate of 0.63 per 1,000, as against 1.06 in the same quarter last year. From small-pox there were two deaths out of 14 cases notified. The only other noteworthy figures are 68 deaths from whooping-cough, as compared with 104, and 60 deaths from measles, as compared with 224 in the March quarter last year. There was also a considerable drop in the death-rate from bronchitis and pneumonia. The 14 small-pox cases were spread over seven districts, mostly in the south-east part of the county, not far from Manchester. The whole of the cases were isolated, and as a measure of precaution a very large number of vaccinations have been done. The number of notifications of tuberculosis rose in the same periods from 797 to 1,026. The figures for whooping-cough and measles fully bear out the statement of the medical officer of health for Manchester that for the moment whooping-cough, which is not notifiable, is a worse form of illness than measles. In Manchester, for the eight weeks ending April 29th, there were 102 deaths recorded from whooping-cough, as compared with 11 in the corresponding period in 1915, while there were 37 deaths from measles this year, as against 163 last year, during the same eight weeks. The number of cases of measles notified is very large, and about one-sixth of them are German measles. The isolation of measles, which is now insisted on, cannot, it is believed, fail to lessen the spread of the disease, which last year had a free course, as children were often to be seen in public conveyances or playing in the streets while covered with the rash.

The report on the working of the Midwives Act in Lancashire shows that there were 920 midwives on the roll, of whom the large number of 487 were only on the roll by virtue of having been in bona fide practice before the Act came into operation. During the quarter there were 644 records of midwives having sent for medical aid, of which 151 were for the newly-born, and 493 for the mothers. The number of cases of puerperal fever which came under notice was 28, with 8 deaths. Only 12 of these were notified by midwives, though 16 of the confinements appear to have been attended by midwives alone, 6 by doctors alone, and 6 by midwives acting under doctors. In 7 cases charges were made against midwives of negligence or misconduct in connexion with cases of puerperal fever, and a number of other charges were dealt with of failure to summon medical aid when the rules required it. During the quarter there were 95 cases of ophthalmia neonatorum reported, and investigation showed that in 13 cases midwives had failed to comply with the requirements in these cases.

INSPECTION OF SCHOOL CHILDREN.

The annual report of the school medical officer for Bootle, Dr. W. A. Daley, contains information showing the benefits derived from medical inspection. The cost of this for a period of twelve months was 11.7d. a child. The number of new cases inspected in 1915 was 1,109, compared with 900 in 1914. The number of children in the schools with some physical defect reached the high percentage of 81.2; 8.6 per cent. were ill nourished, 23.7 suffered from enlarged tonsils, 37.4 per cent. showed four or more carious teeth, and 17.86 per cent. suffered from defective vision. All these percentages were higher than in the previous year. The nutrition of 7.11 per cent. was excellent, and 84.3 per cent. was normal; 7.48 per cent. of the children were recorded as dirty. Systematic examination of the heads of the girls was made by the school nurses, and of 5,531 inspected 1,103 were found to have very dirty heads. It was sufficient to draw the attention of the parents in 714 cases for the neglect to be remedied. In the remaining 389 improvement seemed extremely difficult to obtain. Dr. Daley draws attention to the fact that as lice are regarded as typhus carriers and typhus fever is not unknown in the vicinity, care should be given to this condition and every endeavour made to keep the children from becoming verminous. A beginning has been made to improve the condition of the children's teeth, and a dental surgeon was appointed in October last. Of 202 children examined during the last three months of the year, only 15 per cent. had all the teeth sound.

DOMESTIC DESTRUCTION OF REFUSE.

Dr. T. W. N. Barlow, medical officer of health for Wallasey, in his report to the Health Committee, urges the importance of householders burning their refuse, in view of the fact that the sanitary service is being depleted owing to the demands of the military authorities. He foresees that the weekly collection of house refuse will perforce become a fortnightly, and later on a three-weekly, collection. Dr. Barlow says: "If it could be rendered certain that all the refuse collected from houses was innocuous—that is, burnt refuse—it could not only easily be dumped on waste ground without offence as the clinker now is, but no nuisance would arise at individual houses even if the corporation were unable to collect it for a month." He is also of the opinion that the fly pest and its concomitant dangers would be mitigated, if not avoided, by the householder carrying out this suggestion, which indeed ought to be done in normal times for his own and the public welfare.

Canada.

Two MCGILL V.C.'s.

On Tuesday afternoon, April 25th, enlarged photographs were unveiled in the McGill Union of the two McGill men who have won the Victoria Cross. One of them, Captain F. A. C. Scrimger, M.D., a member of the teaching staff of the medical college and a graduate of the university, accompanied the 14th Battalion as its medical officer, which battalion formed part of the first Canadian contingent. The following is the official report of the deed which won for Captain Scrimger the coveted honour of the Victoria Cross:

On the afternoon of April 25th, 1915, in the neighbourhood of Ypres, when in charge of an advanced dressing station in some farm buildings, which were being heavily shelled by the enemy, he directed, under heavy fire, the removal of the wounded, and he himself carried a severely wounded officer out of a stable in search of a place of greater safety. When he was unable alone to carry this officer further, he remained with him under fire till help could be obtained. During the very heavy fighting between April 22nd and 25th Captain Scrimger displayed continuously day and night the greatest devotion to his duty among the wounded at the front.

Captain Scrimger is the son of the late Reverend John Scrimger, D.D., Principal of the Presbyterian College, Montreal. Fortunately Dr. Scrimger lived long enough to learn of the heroism of his son. Two days previously, on April 23rd, 1915, another McGill man, the late Lance-Corporal Fred Fisher, of the 13th Battalion, who did not live to know of the honour bestowed upon him, gained the Victoria Cross under the following circumstances:

On April 23rd, 1915, in the neighbourhood of St. Julien, he went forward with the machine gun, of which he was in charge, under heavy fire, and most gallantly assisted in covering the retreat of a battery, losing four men of his gun team. Later, after obtaining four more men, he went onward again to the firing line, and was himself killed while bringing his machine gun into action under very heavy fire in order to cover the advance of supports.

The photographs, both of which are excellent likenesses, were unveiled by Sir William Peterson, the principal of the university, who proudly referred to the fact that between 1,400 and 1,500 names are now on the honour roll of the university. "I know," he said, "of no greater proof of the righteousness of this war than the fact that in our somewhat disjointed empire there was not a single constituent part that hesitated for twenty-four hours as to whether she should take the place that she might rightfully claim by the side of the British forces."

CANADIAN CASUALTIES.

Sir Robert Borden, on March 31st, informed the House of Commons that since the commencement of the war the casualties in the Canadian forces had amounted to 22,000. Wastage, apart from casualties, had amounted to 21,700. Enlistment of all ranks had amounted to a total of 290,000, the effective fighting force being therefore 247,000, of which 112,000 were then overseas and 135,000 in Canada. The total expenditure by Canada for war purposes up to the end of February had been \$187,000,000.

Correspondence.

THE INTERNAL USE OF POTASSIUM CHLORATE.

SIR,—The great value of the internal use of potassium chlorate in bad cases of follicular tonsillitis in children and young adults, and in ulcerative stomatitis of children, needs no confirmation, one would suppose, but for many years there has been a profound mistrust and even fear of the internal use of this drug on the Continent. For instance, half a gram ($7\frac{1}{2}$ grains) for a child of 5 years suffering from bad follicular tonsillitis may be regarded by some young doctors as a high, if not a dangerous, dose, though it is well within the ordinary limits. According to Tappeiner's *Lehrbuch der Arzneimittellehre*, grave toxic symptoms may be produced by 2 to 3 grams in children, and by 8 to 10 grams in adults, the toxic action being favoured by concentration of the solution, emptiness of the stomach, and diminished excretion owing to renal disease; the toxic action is likely to commence when the potassium chlorate is present in the blood to the amount of over 0.025 per cent. In Hutchison and Collier's *Index of Treatment* (first edition) it is, as everywhere else, recommended for ulcerative stomatitis in children, "a child of 4 or 5 years taking as much as 25 grains daily in divided doses."

I would ask, then, What are the grounds, if any, for the extreme mistrust of the internal use of the drug which has developed, at all events at some centres of teaching, on the Continent? One of the reasons is possibly the belief that the curative action may be obtained equally well by the local external use of the drug in the form of a mouth-wash or gargle. But I am convinced that the efficacy of the drug depends partly on its excretion from the circulating blood into the mouth. Gargles and mouth-washes may, of course, on account of the likelihood of their being swallowed, be more risky in the case of young children than the internal use of the drug in prescribed doses. Before Behring's discovery of diphtheria antitoxin potassium chlorate was much used internally in cases of diphtheria, and its supersession in diphtheria may have contributed to its relative neglect on the Continent in follicular tonsillitis.

The main purpose, however, of this letter is, if possible, to obtain information as to whether severe toxic results have really been known to follow moderate doses of the drug. I have heard much of the dangers of the drug from young Continental doctors, but in England I have never observed or heard of untoward effects of moderate doses in cases of ulcerative stomatitis in children or in cases of follicular tonsillitis, even when the latter disease has been associated with considerable fever and slight temporary albuminuria.—I am, etc.,

London, W., April 29th.

F. PARKES WEBER.

THE INGUINAL INCISION FOR INTRASCROTAL AFFECTIONS.

SIR,—Arising out of Mr. Maylard's memorandum (April 22nd, p. 589) I have to say that the inguinal incision for intrascrotal affections is one I have practised for at least twenty-four years with convenience and advantage. In this I agree with him, as no doubt do many others. Perhaps in adopting this practice we did not always bear in mind the analogy of scrotal hernia, which in herniotomy is operated on through an inguinal incision.

I do not think that the elaborate attempts to disinfect the scrotal skin which many of us made in the days when we applied irritating antiseptics to the skin, and even wound, are any longer required, now that we avoid irritating the wound, with the increased primary discharge of blood and serum and the consequent encouragement of decomposition, set up by such irritation. But whether operating through the groin, or the scrotum itself as we have to when the latter is ulcerated, I have not found real difficulty in keeping the wound aseptic when the dressings cover and support the genitals, leaving the penis protruding through them. I well remember in those days, especially when mercuric chloride was the disinfectant used and also applied to wet the dressings, the abundant collection of epidermis and exudation with their pungent odour, even when the wound remained sterile. A single disinfection with iodine solution, or with carbolic lotion 1 in 20, as advised by Lister, during the anaesthetic process, and the use of dry cyanide or plain gauze at the dressing, with the greatly lessened discharge, leaves the scrotum harmless, even if not thoroughly disinfected. —I am, etc.,

RUSHTON PARKER,

Professor of Surgery in the University of Liverpool;
Lieutenant-Colonel 1st Western General
Hospital, R.A.M.C.(T.F.).

Liverpool, April 30th.

JEJUNOSTOMY AND JEJUNO-COLOSTOMY.

SIR,—Dr. Victor Bonney is much to be congratulated on bringing forward a new method offering an improved prospect of successful treatment for the very dangerous cases in which persistent symptoms resembling those of intestinal obstruction follow an abdominal operation. He has a friendly difference of opinion with his colleague, Mr. Sampson Handley, as to the cause of the conditions discussed, and I should like to be allowed to add a third view. Handley, as I understand him, attributes the symptoms to peritonitis. Bonney says: "It is to changes occurring inside the bowel that the symptomatology must be ascribed." As long ago as 1887 I argued that the symptoms in these cases are due to a weakening of peristaltic action caused by manipulation and exposure of the bowel, but since reading Professor Arthur Keith's most instructive Cavendish lecture,¹ it seems to me that a temporary lack of co-ordination between the different parts of the intestine is also an important cause.

In 1914 I recorded certain cases in which deaths which appeared inevitable were prevented by draining the caecum or the small intestine, nothing more being required to effect a cure except the closing of the fistula. In these cases there was certainly no true obstruction and no true paralysis of the bowel, and I claimed that the histories proved that only a short rest of the intestine was required.

In his paper in the *JOURNAL* of April 8th Handley dates his interest in these cases back ten years, and I am disappointed that in the four previous years, when we worked together at the Samaritan Free Hospital, I failed to give his views a slightly different bent. In my first paper on this subject it was stated that "a general peritonitis—in the absence of septic influences—is one of the rarest complications of operations involving division of the peritoneum," and that few patients die from these operations without signs of diffuse peritonitis being found at the autopsies. This peritonitis was at that time supposed to be the cause of death, but I showed that there was no sign of peritonitis during an interval after distension and vomiting were well developed, but before the patient was moribund. Handley urges anew that general peritonitis found after death is not necessarily a confirmation of a diagnosis of general peritonitis during life, but he does not carry his argument to the conclusion that the distension of the intestine is the cause of the spreading of the peri-

tonitis, and yet he is careful to reduce distension in treating these cases. He cannot prevent the spreading of the peritonitis unless he avoids or relieves intestinal distension, and when this distension is relieved the peritonitis is harmless or requires peritoneal drainage.

Bonney's cases, like my own above mentioned, seem to offer an absolute proof that only drainage of the intestine and a short rest for the bowel are necessary to effect a cure. He attributes the deaths, when death occurs, to absorption of poisonous fluids. On the other hand, one of Handley's points is to save this fluid for the body as much as possible. In 1893 I recorded² that in certain cases after the abdomen was very large, and vomiting of black foul-smelling fluid was copious, so that death seemed unavoidable, a sudden relief occurred, apparently from a shifting of some plug of faeces in the colon. These cases were first observed when opium was given in full doses for a week after every abdominal section, and the improvement was not accompanied by an action of the bowels. Only gases escaped, but the distension quickly passed off, vomiting immediately ceased, and the general condition rapidly improved. A large quantity of intestinal fluid must have been absorbed when this improvement was taking place, whereas when the fluid was being thrown out freely the patient's condition was rapidly deteriorating. This evidence seems to show that the fluid is not so very septic, and Bonney on April 22nd wrote of its escape from a jejunal fistula that "although the fluid must be highly infective it does not seem to affect the wound to a marked degree."

It seems to me that in these cases death is due to heart failure and starvation. The distension of the intestines and of the abdomen offers an increasing opposition to the blood flow, and the heart is further hampered by direct pressure, whilst enormous quantities of fluid are lost to the body, and the provision of fresh nourishment in adequate amount is impossible. Nevertheless, until the patient is almost moribund relief of the distension may effect a rapid cure.

I agree with Bonney that the urgent necessity in these cases is drainage of the intestine, and the point that attracts me in his paper is not specially emphasized by him nor even definitely mentioned. I refer to the proof that we can drain the small intestine upwards. It is obvious that the small intestine very easily discharges its contents into the stomach if their passage down the bowel is interfered with; but I did not know until now that the passage upwards through the duodenum, stomach, and oesophagus offers a sufficient obstruction to bring about the immense abdominal distension which occurs in the cases under consideration. I have hitherto endeavoured in these cases to open the intestine high enough to drain its healthy part, but otherwise as low as possible. If, however, it can be drained upwards, we can always with certainty relieve intestinal distension, and Bonney assures us that for some little time the patient need not die of starvation. His plan appeals to me strongly, and I shall try it on the first suitable opportunity. Nevertheless these difficulties should be avoided if possible, and I have now on a considerable number of occasions opened the caecum when I anticipated danger from retention of gases. This has been followed often by the most uninterrupted recovery, so that the procedure appeared quite unnecessary, but it does not follow that my fears would have been groundless if the fistula had not been made.—I am, etc.,

London, W., May 8th.

JOHN D. MALCOLM.

TYPHUS FEVER.

SIR,—In the excellent review of Dr. Jeanneret-Minkine's monograph on typhus, published in your issue of April 29th, one sentence needs qualification. Speaking of the author's views on prognosis, your reviewer says: "It (prognosis) is better among the well-to-do and the courageous than among the poor and depressed." Dr. Jeanneret-Minkine indeed cites certain statistics of Curschmann which show a higher fatality rate among the poor than among the rich, but he explicitly calls attention (p. 90) to the enormous fatality seen among medical men, and implies that the rate was also above the average in the case of the prosperous classes of Serbia, a circumstance which he attributes to intestinal

¹ *West London Medical Journal*, 1915, p. 145.

² *The Physiology of Death from Traumatic Fever*, p. 81.

auto-intoxication consequent upon an almost exclusive meat diet.

The high fatality of epidemic typhus among the more prosperous classes has been commented on by numerous writers, especially Graves (*Clinical Medicine*, pp. 59-60) and Creighton (*History of Epidemics in Britain*, vol. ii, p. 100 et seq., and especially pp. 290-1). Jeanneret-Minkine's observations fall into line with those of earlier writers. Davy and Brown's figures (*BRITISH MEDICAL JOURNAL*, November 20th, 1915) are consistent with the fatality-rate upon the medical officers being above the general average, but the absolute numbers are small.

The point is of both theoretical and practical interest, which is my excuse for calling attention to it.—I am, etc.,

M. GREENWOOD, Jun.,

Captain 1st London (City of London) Sanitary Co.

Loughton, May 2nd.

THE "SOLDIER'S HEART" AND ITS RELATION TO THYROIDISM.

SIR,—I do not think that Dr. Harry Campbell is quite correct in his supposition that Sir James Barr is the first to draw attention to the hormonal origin of the symptoms of "soldier's heart."

Some months ago, in the *Lancet*, January 8th, 1916, Dr. Hernaman-Johnson and Dr. Percival White pointed out the fact that "soldier's heart" is really due to Graves's disease, and therefore can be cured by x-ray treatment. At the discussion on "irritable heart" at the Royal Society of Medicine on January 18th, 1916 (reported in the *February Proceedings of the Royal Society of Medicine*), I brought forward the same view, but got no support from the meeting. In the *Lancet* of April 8th I again urged the same fact, and quoted cases cured by x rays to prove the contention.

That the thyroid is not primary in Graves's disease, but that toxic influences play a large part in causing thyro degeneration, few will deny.

Sir James Barr's paper is very valuable as again pressing this connexion. His method of treatment is considerably less laborious than x-ray treatment, which latter, however, gives very satisfactory results.—I am, etc.,

FLORENCE A. STONEY, M.D., B.S.Lond.

London, W., May 1st.

INFANTILE MORTALITY.

SIR,—When Dr. S. G. Moore said in his Milroy Lectures that there was nothing to prevent the continuance in the decline of the birth-rate, he surely did not mean that it would continue declining until it equalled the death-rate. He must know that the birth-rate of Australia and New Zealand ceased falling some ten or more years ago, and that ours may be expected to do the same when serious poverty has been eliminated. The scheme which he favours of public assistance to necessitous mothers and infants will merely ensure that the further decline of our birth-rate will be mainly among the people with over 30s. a week.—I am, etc.,

London, S.W., May 8th.

BINNIE DUNLOP, M.B., Ch.B.

IN an address delivered at the second scientific Pan-American Congress at Washington on January 7th, Mr. Frederick L. Hoffman stated that the estimated annual mortality from cancer in the continental United States is 80,000 (32,000 males, 48,000 females). Excluding cases of disease of the generative organs and the breast, the rates for the two sexes in the registration area of the United States, are about the same. The rate is somewhat higher in urban than in rural centres, the difference being partly accounted for by deaths in institutions. The death-rate in thirty southern cities was 80.3 per 100,000 of population among whites and 55.2 among the coloured. There has been a considerable increase in the negro rate since the Civil War, particularly in cancer of the uterus. A comparison of the cancer mortality rates in the eastern and western hemispheres seems to show a decrease in prevalence corresponding with diminishing distance from the equator. For the eastern hemisphere the rate was 98.3 and for the western 78 per 100,000 of population. There would seem to be a very close relation between the frequency of cancer and the degree of civilization. The disease was extremely rare among the North American Indians, the Eskimos, and West Indian negroes.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following candidates have been approved at the examination indicated:

SECOND M.B. (Part II, Pharmacology and General Pathology).—B. F. Ammitage, H. Barbash, P. F. Bishop, C. V. Brainbridge, E. P. Brockman, G. E. Burton, T. A. Butcher, S. P. Castell, C. B. Cohen, A. J. Copeland, E. C. Curwen, J. C. Davies, C. C. R. Downing, G. A. Fisher, W. S. Gross, A. C. Halliwell, J. C. N. Harris, A. T. Hawley, W. M. Heald, T. L. Hillier, S. C. Ho, P. C. Livingston, A. G. F. McArthur, E. G. D. Murray, P. M. Neighbour, J. W. McK. Nicholl, F. C. Odling, R. A. Olphert, F. P. N. Parsons, R. H. Reece, R. H. O. B. Robinson, N. Rumbold, E. D. Spackman, H. F. Squire, W. S. Sykes, M. S. Thomson, G. H. Ward, J. P. Wells, R. L. Williams, D. W. Winnicott, J. M. McC. Wright.

UNIVERSITY OF EDINBURGH.

GENERAL COUNCIL.

At the statutory half-yearly meeting of the General Council, on May 3rd, resolutions were adopted recording the Council's appreciation of the services of late Principal Sir William Turner, Emeritus Professor Sir Alexander R. Simpson, Emeritus Professor John Wyllie, Dr. Allan Jamieson, and Professor Hardie.

The draft ordinance for the Degree in Education, which will be one of the most comprehensive in any English-speaking university, was approved.

The report of the Finance Committee showed that the total of matriculated students for the year 1914-15 was 2,417 (1,941 men, 476 women). There had been a marked decrease both of men and women in all the faculties except that of science, where there were eight more women than in the previous year. There was an increased deficit in the General University Fund, the deficiency now amounting to £12,814—a fact which showed the need for unappropriated donations. The increase in bursary funds ought not to be allowed to distract attention from this urgent and more general need.

A motion to provide that all future appointments of principals and professors should terminate either at a definite age limit or after a definite period of office, was adopted, with the addition of the words "unless the university shall request such principal or professors to continue in office thereafter for a further period."

The name of Mrs. A. B. Lothian (née Maccallum), M.B., Ch.B., D.P.H., was added to the Business Committee.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

At its quarterly meeting, on May 2nd, the Royal College of Physicians of Edinburgh resolved to offer its diploma of membership to Major Harold Edgar Priestley, Captain Alan Canliffe Vidal, and Captain James Lafayette Lauder in appreciation of their conduct as physicians at Wittenberg.

Obituary.

JAMES BROWN BIRD, M.D. EDIN.,

PHYSICIAN, CUMBERLAND INFIRMARY.

DR. J. B. BIRD, of Carlisle, died of influenza on April 22nd at the early age of 47. He was born in 1869 in Berwickshire, and received his professional education at Edinburgh University; he was Stark Scholar for post-graduate research in 1888-9, and graduated M.B., and C.M. in 1890. After holding a junior resident appointment at the Crichton Royal Institute, he was appointed house-physician to the Brompton Hospital for Consumption, and his studies in that institution afforded the subject for the thesis on phthisis for his M.D. degree, conferred upon him in 1897. In 1891 he became house-surgeon to the Cumberland Infirmary, Carlisle, and when the period of office elapsed he set up in practice in that city. He was placed on the honorary staff of the infirmary in 1897, and became full physician in 1903. He was largely instrumental in founding the Cumberland Sanatorium, for which he was secretary for many years, and he was for a time president of the Burns Club. In 1906 Dr. Bird was Chairman of the English Division of the Association and President of the Border Counties Branch in 1910. In 1896, when the annual meeting of the Association was held in Carlisle, he was active in its organization. He was universally respected by his fellow citizens, and at the funeral, on April 25th, a large and representative gathering assembled at the service held in St. Paul's Church, Carlisle. He was held in high esteem by his professional brethren, and his death is greatly

deplored by them. In addition to a large general practice he was very rapidly securing a considerable consulting practice both in the north of England and in the south of Scotland, and his opinion, founded on much careful bedside work in hospital, carried great weight both with the patients and their medical advisers. Unfortunately his death has come before he had made that due provision for his family which he would have liked, and an influential committee has been formed for the purpose of raising a memorial fund for the education of his children. Already £800 has been promised, and, in view of the widespread public sympathy shown, it is expected that a considerable sum will be obtained.

DEPUTY SURGEON-GENERAL C. J. MANSFIELD,
M.V.O., M.D., R.N.

AFTER an illness of four weeks (suppurating cervical glands followed by septicaemia) Deputy Surgeon-General Mansfield died on May 7th at Haslar, where he had worked as senior medical officer of the medical section since July of last year. Born on June 19th, 1861, he was the youngest and only surviving son of the late Rev. Edward Mansfield, vicar of Highnam, near Gloucester, and was a descendant of the well-known Chief Justice of Common Pleas, and a relation of Lord Sandhurst. He was educated at Cheltenham, qualified M.B., C.M. at Aberdeen in 1883, and proceeded to M.D. in 1896. Entering the Royal Navy in 1885, he subsequently had an extensive experience in the cadet and boys' training establishments of the Royal Navy, having been surgeon in the old *Britannia* (1892-3), fleet surgeon at the Royal Naval College, Osborne (1905-9), while the present Prince of Wales was in residence, and in H.M.S. *Impregnable* (1911-13). After the last appointment he was deputy surgeon-general at the Royal Naval Barracks, Chatham (1914-15). A hard-working officer, he was most unselfish and kindly to patients and colleagues alike, and was therefore universally respected and beloved. He made some contributions to medical literature, but his memory will be mainly preserved in the affections of his numerous friends. He was created M.V.O. (Fourth Class) in 1909. The naval funeral took place at Haslar on May 10th.

JAMES GILBERT HOPE, whose death at his house, 6, Royal Circus, Edinburgh, occurred on May 6th, was 42 years of age. He passed the examinations necessary for the triple qualification (L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg.) in 1898, and settled in private practice in the Comely Bank district of Edinburgh, his residence being next door to the house once occupied by Thomas Carlyle. He was one of the medical officers to the New Town Dispensary and visiting physician to the Livingstone Dispensary of the Edinburgh Medical Missionary Society. He had also served as house-surgeon to the Ear, Throat, and Nose Department and as clinical assistant to the Skin Department in the Edinburgh Royal Infirmary. He is survived by his widow and four children.

DR. JOSEPH WILLIAM SMITH, J.P., died rather suddenly on April 12th at Weaverham, Northwich, Cheshire, where he was born in 1844. He was the son of the late Dr. Samuel Smith, who had two other sons in the profession. He received his education at King's College, and took the diplomas of M.R.C.S., L.M., and L.S.A. in 1866. He became a leading practitioner in mid-Cheshire, and was highly popular with all classes, as it was recognized that his main aim was to do good to others, whilst he set before himself the highest ideals of citizenship. Dr. Joseph Smith was surgeon to the Northwich Infirmary, and an original member of the Cheshire County Council, on which he sat as representative of Weaverham from 1889 to 1913; he also held a number of public appointments. A few years ago he was presented by his numerous friends with a valuable motor car, and a garage was built for him.

DR. ALEXANDER BARR POLLOCK, who practised for thirty-five years at Hillhead, Glasgow, died on April 27th, in his 66th year, after a prolonged illness. He was the youngest son of the late Mr. William Pollock of Tradeston. Dr. Pollock graduated M.D. and C.M. Glasg. in 1879, and for a

time assisted the late Professor's Sir George Macleod and George Buchanan. Two of his five sons are members of the medical profession and two are serving in the army.

THE HON. JAMES HERBERT HUGH HARRISON, J.P., principal medical officer British Honduras, died suddenly at Belize, British Honduras, on May 5th, aged 52. He was educated at University College, London, and took the diplomas of M.R.C.S. and L.R.C.P. in 1889, and subsequently that of D.T.M. Liverpool. He was resident medical officer at Belize, and became a member of the Legislative Council, British Honduras. He was also a Fellow of the Royal Geographical Society.

DR. JAMES ROBERTSON died at the age of 73 at his residence, Fricockheim, Forfar, at the end of April. His mother was a cousin of Mr. W. E. Gladstone. He took the diplomas of L.R.C.P. Ed. and L.F.P.S. Glasg. in 1868. Dr. Robertson was well known and highly esteemed in the district in which he had resided for many years after his retirement, as he was ever ready to give health and relief, especially to the poor. He began his professional career as a medical missionary in Calabar, and, returning to this country, practised for a number of years in Auchencairn, Ayrshire, and, later, for a shorter time in Birmingham.

DR. CHARLES JOHN GRELLET died at his residence in Hitchin, Herts, on April 23th, aged 73 years. He began his professional career as apprentice to Sir Cordy Burrows of Brighton, and afterwards studied at St. Bartholomew's Hospital. He took the diplomas of M.R.C.S. and L.S.A. in 1864. After holding the appointment of surgeon to a colliery company at Clay Cross, he became Admiralty surgeon at Oxford Ness, Suffolk, and finally, in 1871, settled at Hitchin, where he practised till his death. Dr. Grellet was surgeon to the North Herts and South Beds Hospital at Hitchin until five years ago, when he was placed on the consulting staff. He was much esteemed for his courtesy, his devotion to duty, and his zeal for the welfare of the town in which he had practised for nearly half a century. Two of his four sons practise in Hitchin, and a third, Captain R. C. Grellet, 8th Yorkshire Regiment, is now in France.

LIEUTENANT-COLONEL WOODFORDE WOODFORDE-FINDEN, Bengal Medical Service (ret.), died in a nursing home at Harrow, after a long illness, on April 27th, aged 71. He was born on July 18th, 1844, the only son of the late George Corfield Finden, of Gloucester Terrace, Hyde Park. He was educated at King's College, London, and in Paris, took the diploma of M.R.C.S. in 1865, and that of L.R.C.P. Edin. in 1866. He entered the Indian Medical Service as assistant surgeon on October 1st, 1866, became surgeon on March 1st, 1873, surgeon-major on October 2nd, 1878, and brigade surgeon lieutenant-colonel on November 2nd, 1891, and retired on December 21st, 1896. He put in all his service in military employ, chiefly in the 2nd Gurkhas. He served in the Afghan war of 1878-80, when he took part in Roberts's march from Kabul to the relief of Kandahar, and in the battle of Kandahar, being mentioned in dispatches, in G.G.O. No. 556 of 1880, receiving the medal with a clasp and the bronze star; in Burma in 1887-88, medal with clasp; and on the north-west frontier of India, in the second Miranzai campaign of 1891, clasp.

DR. MIGUEL A. FARGAS Y ROCA, professor of obstetrics and gynaecology in the University of Barcelona, was recognized as one of the leading authorities on his speciality in Spain. He was a brilliant teacher who, with scanty material, built up a successful clinic in the Hospital de Santa Cruz. He was a pioneer of aseptics in Barcelona, where, as Dr. Blanc expressed it, in referring to his death at a meeting of the Sociedad Ginecológica Española on February 23rd, he "operated aseptically in a septic hospital." Professor Fargas did good work in general surgery as well as in his own chosen field of practice. He was an honorary Fellow of the Spanish Academy of Medicine.

DR. HENRI Secrétan, who died on March 5th at the age of 60, was recognized as the leading authority in Switzerland on accident assurance. He was a son of the distinguished philosopher, Charles Secrétan, and, after studying at Lausanne, Geneva, and Pisa, took his doctor's degree at the Paris Faculty in 1885. In the same year he began the practice of medicine at Lausanne. He embodied the fruits of his experience in a number of writings on acute abscess of the lung, the treatment of chronic serous effusions, hydrophobia, the treatment of wounds and other subjects. Twenty years ago, when assurance against accidents first came within the sphere of practical politics in Switzerland, he turned his attention to that new field of medicine. He collected a number of articles into a volume, entitled *L'Assurance contre les accidents*, founded wholly on his own experience; it has passed through three editions. Secrétan was a man of wide culture and varied intellectual interests. He wrote on the depopulation of the Roman Empire and the Germanic invasions; the end of the empire of the West and the beginning of the Middle Ages; Christian propaganda and persecution, and other historical and sociological subjects.

The Services.

EXCHANGE.

M.O. Wessex Division, at present under canvas at Hursley Camp, would like to exchange with Territorial M.O. serving in Portsmouth district. Address No. 1750, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medical News.

WE regret to have to record the death of Dr. Arnold Lea, surgeon to St. Mary's Hospital for Women and Children, Manchester, which occurred on May 7th. We hope to publish some account of his life in an early issue.

THE Government of Panama has established a national department of Uncinariasis or Tropical Anaemia for the organization and conduct of an active campaign against the disease in the territory of the republic.

DR. PHILIP GELL GARRETT and six more nurses have gone out this week to Corfu, under the auspices of the Wounded Allies Relief Committee, of Sardinia House, Kingsway, W.C., to the relief of sick and wounded Serbian soldiers.

THE first Pan-American Congress on Childhood will be held at Buenos Aires in July next. Dr. Julieta Lauteri Renshaw is president of the organizing committee. The work of the congress will be divided among seven sections, which deal with infant legislation, industrial legislation, hygiene, education, psychology, aid to the mother and the child, and sociology.

A MEETING of mobilized chemists was held at Angoulême on April 23rd to consider the question of founding a general union of the chemists of France. The object of the proposed organization is to form a combination of all French chemists for the study of questions relating to chemistry in general, and in particular to enable French chemical science to compete successfully with the powerful German organizations.

AT the meeting of the Röntgen Society on May 2nd, Major Robert Wilson of the Canadian Medical Service showed an enclosed tungsten arc lamp which he has devised for the treatment of wounds by ultra-violet radiation. His idea, he said, had been simply to produce a lamp much more cheaply constructed than the ordinary arc lamp in use at some of the hospitals, and more effective than the Finsen-Reyn lamp. As a result of experiment, he found it best to have a pure tungsten base as one electrode and carbon cored with tungsten powder as the other. The tungsten powder was made into a paste and forced into the central cavity of the carbon, being reduced in the intense heat which followed when the arc was formed. Various pairs were tried but nothing answered so well as these. The spectroscopic results showed the issue of radiation having wave lengths of 2,000 Angström units, and the arc had the advantage of being steady and free from sputter. He had several diaphragms available, but one great desideratum was to have the application of the rays upon the part as cold as possible. In order to direct the radiation, he used a mirror having such a curvature as to give a very slightly divergent ray at a distance of 12 in. from the light source.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

QUERIES.

LOCAL ENDARTERITIS.

A. F. F. asks whether it is possible to have endarteritis absolutely blocking the axillary artery in its first part. No evidence elsewhere.

* * We have been unable to find any case recorded in which a strictly localized endarteritis has blocked an artery the size of the axillary. Thrombosis following local injury seems the likeliest cause of blockage in the case; or embolism; or spread of thrombosis from aortic aneurysm—though this would be excluded if the subclavian artery was unaffected.

ANSWERS.

LEUCODERMA.

DR. S. J. ROSS (Bedford) writes in reply to "L.R.C.P.": In two cases of leucoderma which have been under my care benefit was derived by the use of a lotion of mercury perchloride (1 in 1,000). In the syphilitic variety antisyphilitic remedies will prove of value.

LETTERS, NOTES, ETC.

COLD FEET AND STUFFY HEADS.

DR. E. LLOYD OWEN (Criccieth) writes: Professor Leonard Hill, F.R.S. (writing in the BRITISH MEDICAL JOURNAL for April 8th), probably rightly regards a cold in the head (and he might add diphtheria and most other infectious diseases) as most commonly due to infecting microbes transmitted in masses to a person through the saliva spray or mucous spray of another present in more or less close propinquity in the same room, that room being most frequently at the time imperfectly ventilated, and the microbes perhaps finding a favourable opportunity to commence operations after their new host has gone out into the cold air.

Such an imperfectly ventilated room would, in Dr. Hill's opinion, be one which is over-heated (this, however, being possibly accompanied by a cold draught at the level of the feet), and in which the air is over-humid and also too still and monotonous. Dr. Hill having found that, while the rate of cooling at the foot level in the House of Commons was high, that at the head level was low, remarks that this condition of things (cold feet and stuffy head, as he terms it), is not the best for our legislators.

But is he right? It may be granted that the conditions may not be altogether comfortable, but one would think, unless the feet are so cold as to distract the attention of the owners from the matter of debate, that by allowing blood to fill the brain (not the nasal mucous membrane merely), cold or at least cool feet would tend to mental alertness. Stuffy noses do not necessarily mean stuffy brains.

Are not cool feet and a warm brain the antithesis of the conditions that obtain when one is in bed asleep? Is there not during sleep a certain amount of anaemia (in spite of the horizontal attitude), resulting from determination of blood to the feet, and indeed to every part of the body covered by the bedclothes? My own experience is that to remain in a warm, luxurious bed, with only the head out, even after a prolonged sleep of eight or nine hours, is not very favourable to hard thinking. I fancy that I have read of some eminent authors who testified that some of their best work had been done with cold feet (or rather, while their feet were cold).

So I should say that cool feet and warm heads are, instead of the worst, the very best conditions for our legislators. On this matter depends the question whether fresh air inlets should be placed as low as possible (as hitherto in the House of Commons) or at a higher level.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Notes on Military Orthopaedics.

III. THE SOLDIER'S FOOT AND THE TREATMENT OF COMMON DEFORMITIES OF THE FOOT.

BY

LIEUTENANT-COLONEL ROBERT JONES, CH.M.,
F.R.C.S.I. (Hon.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

PART I. FLAT-FOOT.

The foot must be regarded for our present purpose as consisting of two parts: The hinder part, behind the mid-tarsal joint formed by the os calcis and astragalus; and the fore part, in front of that joint, consisting of the rest of the tarsus, the metatarsus and the toes.

The Three Arches of the Foot.

The hinder part of the foot is designed to carry the body weight when standing. The os calcis and astragalus are strongly bound together by ligaments, and the astragalus is securely set between the two malleoli at the ankle joint.

The fore part of the foot is much more mobile, and is designed to give spring to the foot when walking. This spring depends on the efficiency of the small muscles of the foot, on the integrity of the longitudinal and transverse arches, and on the freedom of movement of the toes themselves.

Regarded as a base of support, the foot is a tripod resting on the heel, the head of the first metatarsal bone, and the heads of the fourth and fifth metatarsal bones. Each side of the triangle formed by these three points is arched. The outer side formed by the os calcis, cuboid, and the fourth and fifth metatarsal bones is so slightly arched that practically the whole length of it rests on the ground when standing. This element of the foot is therefore not very susceptible of strain, and need concern us no more.

The inner side is strongly arched; the arch runs from the heel upwards and forwards to the neck of the astragalus, then downwards, forwards, and *inwards* through the scaphoid, internal cuneiform, and first metatarsal bones to the ball of the great toe. This arch, which varies in height in different individuals, is composed of a number of bones, is very susceptible to strain, and is in consequence the seat of a number of disabilities which we shall group together as "flat-foot."

The third side of the triangle runs from the head of the first metatarsal bone to the heads of the fourth and fifth metatarsal bones, and forms the front part of the transverse arch of the foot. It must be remembered that this transverse arch extends backward throughout the whole of the forepart of the foot. The cuneiform bones and cuboid bones are arranged in a transverse arch as well as the metatarsal bones.

Deformities and Disabilities of the Foot.

In considering deformities and disabilities of the foot due value must be given to its various mechanical elements—that is to say, not only to its bony structure but also to the muscles and ligaments which help to maintain its shape.

Looked at in this way we find among the deformities and disabilities of the toes such conditions as hallux rigidus, hallux valgus, and hammer-toe, and we note that the two former in particular are frequently associated with some degree of flat-foot.

Impairment of the transverse arch is specially apt to be associated with the painful condition known as metatarsalgia.

Impairments of the longitudinal arch are associated with a train of symptoms which are found in the various degrees of weak foot, everted foot, and flat-foot.

All these types of derangement of the mechanical elements of the foot and the resulting disabilities depend on strains about the complicated series of joints in the fore part of the foot.

In the hind part of the foot the disabilities are fewer. They are mainly connected with painful conditions of the heel, due to such conditions as strain of the insertion of the tendo Achillis, or periostitis of the os calcis, due to trauma or sepsis.

When a clear idea of these several disabilities and of the measures suitable for the prevention or treatment of each has been obtained, it will be more easy to grasp and understand the various disabilities of the foot to which the soldier is liable, always remembering that two or more types often occur simultaneously, and that all must be appropriately treated.

Flat-foot.

The term "flat-foot" may be taken as a generic term to include all degrees of strain of the longitudinal arch of the foot. To these various conditions different names have been given, which need not detain us here. The point to be understood is that all degrees occur, from slight strain of the ligaments and tendons by which the arch is maintained to complete descent of the arch with osseous deformity, obvious to the most casual observer.

The essential fact in the deformity is abduction and eversion of the fore part of the foot (Fig. 1). If it commences as a sudden acute condition, it is associated with strain of the inferior calcaneo-scapoid ligament; to this is due the tenderness elicited on pressure on this ligament just below the tubercle of the scaphoid. This tenderness is characteristic. Pain in this situation is often most acute in patients who have naturally a very high arch. When such an arch begins to give way the strain on the "spring" ligament is great and the pain correspondingly severe, but the foot is not physically flat, for the arch may still be higher than is normal in most people.

FIG. 1.—Flat everted foot.

As the foot becomes more strained under continued exercise, the bones of the tarsus begin to descend and pain is complained of across the dorsum of the foot.

Finally, when the deformity becomes still greater, there may be pain on the outer side of the os calcis below the tip of the external malleolus. This is probably to be attributed to bruising of the periosteum due to the os calcis impinging on the malleolus; in some cases an adventitious bursa is ultimately produced in this situation.

Acute Flat-foot.

All the above symptoms, and also actual descent of the arch with pronounced abduction and eversion of the foot at the mid-tarsal joint, may come on with great rapidity and then be associated with very severe pain, so that the patient cannot walk and can hardly bear to have the foot touched. Such a condition may fairly be described as acute flat-foot. It occurs in its typical form in people who are in poor physical condition, as, for instance, after an attack of influenza, and return too soon to work which involves much standing and lifting of weights—for example, hospital nurses. It occurs in exactly the same way in the recruit. Take, for example, the clerk who has taken little exercise and who has been in the habit of wearing boots in which there is no room for movement of the toes and bones of the fore part of the foot; all the muscles and ligaments controlling and supporting the arches of the foot are weak and out of condition from want of use; under the strain of hard drill they give way.

Treatment of Acute Flat-foot.

The treatment of such a case falls into three stages.

First Stage.—If the foot is acutely painful the patient should be put to bed and the feet gently massaged for two or three days till the acute tenderness passes off. During this time he must never be allowed to set foot to the ground, for the weight of the body would again strain the ligaments.

Second Stage.—As soon as the acute tenderness has passed off, the foot should be adducted and inverted so as completely to restore the arch, and the foot kept continuously in this position to allow stretched ligaments to shorten and become adapted to the correct position. Mere rest in bed is not enough, for then nothing is done to restore the proper shape of the arches, adaptation takes place in the flat-foot position, and the patient is left with a real flat-foot. It is often best to mould the foot into correct position and fix it in plaster-of-Paris for about ten days to allow the strained ligaments to recover completely.

Third Stage.—When the plaster is removed, after, say, ten days, the patient's foot is exercised—first of all by massage and exercise, particularly movements of the toes and inversion movements, never eversion movements. These inversion movements are intended to strengthen the muscles controlling the arch.

Boots.

The patient is allowed up in specially altered boots. The boots should grip comfortably round the ankle and heel, but the whole fore part of the boot should be roomy to allow free play of the small muscles inside the boot.

FIG. 2.—Boot with straight inner border, crooked and lengthened heel, patch to thicken sole.

Pointed toes are very harmful, as they abduct the fore part of the foot and help to produce the condition of flat-foot. The inner side of the boot should be straight, so that when the two boots are placed side by side the inner sides are parallel right forward to the great toe. This is not the conventional boot of the shoemaker, but it is the correct boot for a strong foot.

The present army boot is not perfect, but it is much better than it was some years ago.

Having seen that the boots are of suitable shape, they should be sent to the shoemaker to have the heels "crooked" on the inner side. By this is meant that the heel of the boot is made a third of an inch higher on the inner side, and tapering gradually to its outer side, so that the inner side of the heel is a third of an inch higher than the outer side. In addition, the length of the heel should be extended forwards by three-quarters of an inch on the inner side, and the sole should be raised one-third of an inch by a patch on the inner side of the sole just below the toe-joint (Fig. 2).

The patient must never put foot to the ground without an altered boot or shoe on, otherwise he will unwittingly let his arch descend and so inflict a fresh strain on the ligaments.

The man should then be instructed to walk with feet parallel, not with the toes turned out. The altered heel helps the patient to keep his toe turned in. Exercises should be graduated till the man is fit for full duty.

A bad case of *acute flat-foot* should be fit for light duty in three weeks, and for full duty with the heels of his boots raised on the inner side in six weeks to two months.

It is really a question whether the army authorities ought not to issue all boots with heels raised on the inner

FIG. 3 A.—Thomas's wrench applied to invert everted foot.

FIG. 3 B.—Showing the position of the foot and direction of force at end of correction to inversion.

side, as this is a great relief to the foot on a long march and increases the man's weight-carrying and lasting power.

Certainly all recruits with weak feet should be started off with crooked heels on the boots until the muscles of their feet get into training. They should also be taught to walk with their feet parallel. If this were done the feet

would grow stronger rather than weaker, and considerably fewer men would require to be taken off duty.

Traumatic Flat-foot.

Flat-foot in every respect similar to that just described as acute flat-foot may arise from injury. For example, when the wheel of a trap runs over a man's foot and strains all the ligaments.

Flat-foot from Periarthritis.

Similar mechanical conditions arise in gonorrhoeal periarthritis when all the ligaments are sodden with exudate, become soft, and stretch. The same is true when the infection is of an ordinary septic character, for if the man puts weight on his foot before the arch is restored to its strength he will get a flat-foot. He can, however, walk with safety in a boot with the heel well crooked almost as soon as the disappearance of pain allows him to put his foot to the ground.

Rigid Flat-foot.

These cases lead us naturally to the rigid form of flat-foot which results from neglect in the acuter stages, whether the cause of the sudden yielding of the ligaments be overstrain due to unaccustomed exertion in walking, to injury, or to weakening of the ligaments by the products of infective agents.

The foot, therefore, should be maintained in the inverted and adducted position during recovery from the acuter conditions, and when the patient begins to walk the body weight should be deviated from the inner to the outer side (Fig. 2). If this important routine should be neglected the recovery of ligaments will occur in a flat-footed position with stiffness in all the joints. The patient in that case cannot stand on the outer edge of the foot or turn it into an arched shape.

Treatment is very simple, but must be thorough. The foot should be wrenched so as to break down all adhesions and make it thoroughly pliable (Fig. 3). The foot is by this means converted into an acute traumatic flat-foot, and it must undergo the course of treatment already described for that condition. It should be moulded into the correct position, and plaster-of-Paris applied. After two or three weeks of such rest, to allow recovery from the trauma, graduated exercise may be taken in boots so altered as to deviate body weight from the inner to outer side of tarsus. An outside iron is often found a great assistance in maintaining the correct position of the foot during walking (Fig. 4).

Osseous Flat-foot.

A real stiff flat-foot which has been neglected for years becomes an "osseous flat-foot"—that is to say, changes occur in the shapes of the bones to adapt them to the erroneous position. Though something can be done to improve such cases, they cannot always be made fit to be soldiers; the surgeon must, however, be sure that he is dealing with real osseous change and not merely with a flat-foot which is rigid owing to ligamentous contractures and adhesions.

Flat-foot due to Spasm of the Peronei.

I described this condition many years ago (Fig. 5), and stated that it was by no means uncommon. It may be found in any out-patient department if looked for, and I have operated upon as many as 150 cases in one year. It occurs usually after puberty and in early adolescence; it is common among the robust, not only among the weakly, and is not associated with the temperament known as neurotic. I will describe a typical case. A young man

FIG. 4.—Outside iron in addition to crooked long heel and piece to sole.

FIG. 5.—Peroneal spasm producing a flat everted foot.

of 18 limbs with a springless gait into the out-patient room. He walks with feet practically rigid and with toes pointing out. They are both everted, and the inner border over the region of the scaphoid appears thickened and even angular. Both the character of the walk and the appearance of the feet might lead to the diagnosis that osseous changes were advanced. On being questioned the patient may give a history of injury such as a fall on the feet; usually he cannot account for the origin of his trouble. The pain is often acute, the feet may perspire abnormally, and the patient may not be able to walk more than a short distance. Relief is experienced on removal of his boots; if he is asked to invert his foot he cannot do it, and when he attempts to do so the peronei become rigid. The surgeon when he examines the foot manually finds there is pain on pressure over the deltoid ligament, over the scaphoid, and over the tip of the external malleolus, where it impinges upon the os calcis, and tenderness over the peronei along the outer border of the foot. If the surgeon gently attempts to invert the ankle much pain is experienced and the peronei, so to speak, immediately place themselves on guard and strongly resist the surgeon's efforts. Now while the surgeon has firm hold of the foot, let him engage the patient in conversation, at the same time gently press in the direction of inversion. Then at the psychological moment, while the peronei are quiescent, very suddenly and very forcibly let the foot be inverted and held there. It is a very painful movement, but the character and contour of the foot is completely changed. It is no longer rigid, osseous changes are obviously absent, and the general appearance of the foot is almost normal. The moment the surgeon releases his hold, the old rigidity and deformity return.

For this condition mechanical measures are of no avail.

FIG. 6.—Exposure of tendons of peronei preparatory to excision of about $\frac{1}{2}$ in.

The patient must be anaesthetized to relax all spasm, and about three-quarters of an inch of each peroneus should be removed about an inch and a half above the malleolus (Fig. 6). The foot must then be fixed for about three weeks, well inverted and adducted at the mid-tarsal joint, and later the ordinary treatment for flat-foot. My old house-surgeon, Mr. Naughten Dunn, secured equally good results by pinching with a pair of forceps the nerve as it enters to supply the peronei. Simple

tenotomy of the peronei is not sufficiently drastic to prevent recurrence of deformity.

Diagnosis.

It is not an easy matter to lay down rules for a hard and fast differential diagnosis between these types of rigid feet, but the following considerations will help.

An osseous flat-foot which has become adapted to its new position is usually strong and painless.

A flat-foot rigid from adhesions and shortened ligaments is still susceptible to strain, and is liable to become painful after unusual exercise.

The type due to a spasmodic contraction of the peronei is characterized by pain, and the spasm may be overcome in the manner I have just indicated.

In the two last varieties, after the deformity has been over-corrected for a time, energetic massage and a correct deviation of body weight are essential elements in bringing about a cure. The osseous type, once the bones have completely dropped, may not only be painless, but may be strong enough to bear the strain of long marches. Wounded soldiers may constantly be met with whose feet are very flat, whose mid-tarsal joints are fixed, but who have undergone several months of hard training without a complaint. If in addition to these osseous changes the power of inversion of the foot is lost or the peronei are in spasm surgical attention is urgently called for.

The flat-foot for clinical purposes may be divided into two classes.

- (a) The foot which the patient can invert.
- (b) The foot which he cannot invert.

The first class will not respond to any mechanical treatment, such as a plate or alteration of the boot. It will not even suffer correction by means of a bandage to

an outside iron from knee to heel. An operation, or forcible manipulation and fixation under an anaesthetic, are essential preliminaries to the simpler mechanical methods.

The second class will never require an operation.

This simple clinical division should be helpful to the military surgeon.

Subacute Flat-foot (Ordinary Flat-foot).

The stage of flat-foot most commonly seen is neither an acutely painful foot too tender to be handled, nor a rigid flat-foot, but an intermediate stage, which may be called subacute.

The patient's feet give him little trouble in ordinary life, but a long walk makes them ache round the instep. When he goes to bed after a hard day's exercise his feet are apt to get stiff. Next morning they are stiff and painful when he gets up, but as he moves about this passes off; but later in the day, especially if he has to do a lot of standing and walking, the feet again become very painful.

Diagnosis.—This is made by considering the patient's history and by finding distinct tenderness on pressure below the tuberosity of the scaphoid; there may or may not be pain in other localities. Finally, the patient can voluntarily stand on the outer edge of his foot and can crook his foot into the arched position. This last point is very important, for it means that the patient will recover if the heels of his boots are crooked so as to deviate body weight on to the outer side of the foot.

The case should therefore at once be put through the last stage of treatment described under acute flat-foot—namely, graduated exercises—and he need not be taken off duty for more than a day or two while his boots are being altered. "Contrast baths" of hot and cold water alternately, to stimulate the circulation of the foot, are a great relief to the patient, especially at night, when his feet may be a little sore and swollen after having been walking about all day.

Conclusion.

I have purposely avoided all mention of tiptoe exercise. These exercises are excellent, but they will not cure a flat-foot if the patient is allowed to come down in the flat-footed position between the period of exercises.

If the principle of deviation of body weight on to the outer edge be loyally adhered to every ordinary case will recover, even without special tiptoe exercise. Loyal adhesion to the principle stated means that the patient never sets foot to the ground except in a properly crooked boot, shoe, or slipper. Even in his bath he must be careful to stand on the outer edge of the foot. The whole idea of treatment is to ensure that uninterrupted adaptive shortening of stretched structures shall take place.

Massage, tiptoe exercises, electric stimulation of muscles all help to hasten the recovery, but a few minutes' careless walking in stocking soles will undo all benefit from other treatment by again stretching recovering structures.

Frequently the high arched foot is the most troublesome type when the tendons are strained and the ligaments begin to give. The strain upon the astragalo-scaphoid joint in this type is, for obvious mechanical reasons, great, and the progress of the affection is often marked by a prominence about the scaphoid due to pressure osteitis.

THE census bureau of the United States Department of Commerce recently issued a summary of its statistics of causes of death in 1914 in the registration area, which comprises 435 cities and towns with populations ranging from 10,000 to 100,000, and represents about two-thirds of the total population of the United States. The total number of deaths was 898,059. Of these, 99,534 were due to diseases of the heart; 96,903 to tuberculosis (of disease of the lung in 84,366 cases); 83,804 to pneumonia; 67,545 to Bright's disease and nephritis; 52,420 to cancer and other malignant tumours; 52,407 to diarrhoea and enteritis; 51,272 to apoplexy; 15,044 to arterial diseases of various kinds; 11,786 to diphtheria; 10,666 to diabetes; 10,185 to typhoid fever; 15,617 to whooping-cough, measles, and scarlet fever. The statistics show that from 1904 there has been a continuous decrease in the mortality from tuberculosis and typhoid fever, while since 1900 there has been an almost continuous rise in that from cancer and diabetes.

THE CAUSES AND PREVENTION OF TRENCH FOOT.

By BASIL HUGHES, M.B., F.R.C.S.,
CAPTAIN R.A.M.C.(T.F.).

The pathologic condition which has been called "trench foot" has given rise to considerable discussion, and from time to time articles by different observers have been published in which various suggestions for its treatment have been made.

The importance of the discovery of the true cause of this condition can hardly be exaggerated, whether it be regarded from the point of view of the internal economy of the service, or that of the permanent disability that may result to the men so attacked.

Despite the conscientious following out of treatment recommended, numerous cases continue to occur, and, in consequence, much thought was given to the condition in the hope that the true cause might be found.

From October to the end of December, 1915, I was attached to a regiment which was holding a section of the line where the conditions were extremely bad. During August and September and July I had been attached to other regiments in the same salient, but the conditions during these three months were not comparable to those obtaining from the latter part of October to the end of December. During the earlier months the dug-out accommodation was good, and men could lie down during the day time; but during the later period many of the dug-outs had either fallen in or had been blown in, the parapet in other places had fallen in owing to the wet, and owing to difficulty in finding suitable soil it was not always possible to repair it. The men, therefore, during the day were unable to move about, and either had to stand or crouch until nightfall. At night they usually slept in a sitting position, when they slept at all.

The first case of trench foot I saw in October was that of a bomber who had been on duty through the night in a wet sap; and the next three or four cases were also of bombers who had been on duty in this sap, and the succeeding cases were sentries who had been in and about the entrance to this sap.

In all these cases the history was identical. The man had felt little inconvenience, except that the feet felt like "pins and needles," and had "gone to sleep." There was time and opportunity for one man at a time to sit down and get his feet up, but this particular sap was in such a bad condition that the one man who could sit could not get his legs up.

On coming off duty in the morning they were able to take their boots off, rub their feet, and turn in to a dug-out. In some of the dug-outs they could lie at full length, in others they were semi-recumbent. During their sleep, despite the fact that their puttees were off, their socks changed, and bootlaces slack, the feet swelled, became red and tender, and the circulation in them was sluggish. The oedema was soft and pitted on pressure. On putting their boots on again these men were unable to walk.

Another class of case I saw was in men who had been on sentry-go. They felt pain in and under the great toe; it spread rapidly to the heel and then along the outer border of the foot. This pain frequently came on during the resting period. Examination showed that the feet in the parts mentioned were red, tender, hot, and to some extent swollen; the condition resembled more the beginning of an acute inflammation than in the preceding cases.

Stage I.—The two above mentioned types of cases were seen in men who reported their condition early and may be called Stage I. It would seem that the exudation causing the oedema in the foot takes place first of all deep to the plantar fascia and extends to the dorsum of the foot, for the same reason that an inflammatory exudation deep to the plantar or palmar fascia usually manifests itself in oedema of the dorsal surfaces. The soles of the feet were very tender to deep pressure.

Stage II.—Men who did not report early, but persevered in treating themselves, and at the same time tried to do their share of duty in the trenches, presented a condition of the feet which differed materially from the stage already described. These men invariably reported twenty-four hours after the first stage had set in. Almost without

exception they told of the rapid onset of the initial swelling of their feet during the resting period, and that while on duty prior to their feet swelling they had noticed no inconvenience beyond some numbness and "pins and needles." The foot was swollen and cold, and the condition sometimes, though rarely, extended to the ankle and slightly above it. Pain was never a marked feature; loss of sensation seemed to take its place. The oedema was of quite a different kind, there was no pitting on pressure, and the feel imparted to the hand was that of a solid rubber ball. Circulation as tested peripherally was extremely sluggish, and in places about the toes it was questionable if it existed, but doubtless it did. This condition might be called Stage II.

Stage III.—The last and final stage is that in which gangrene supervenes. Fortunately, I met with no such cases in my own regiment, though I saw cases of this sort that had reached the hospitals in England late in 1914 and early in 1915.

After the occurrence of the first of my cases I went to the sap from which they had come. I examined the boots, socks, and feet of the men, the adjustment of their puttees, and was soon convinced that the rubbing of the feet was being most conscientiously seen to. The boots were letting in the thick soupy mud over the tops, and in some cases the fact that the tongue of the boot had not been stitched sufficiently high up made the letting in of this liquid mud the more easy. The socks were being frequently changed. In most cases two pairs were being worn, and the boots issued were a size larger than were normally required.

The only cause, or exciting cause, that could then be suggested was the soupy mud of the trenches, and its infective nature; it had come in contact with decomposing organic matter, which was present almost everywhere, and could neither be removed nor kept covered for any length of time owing to the enemy's artillery.

I then ascribed the condition to some infective agent, and set to work to examine cases more closely from this point of view. The socks of the men who came down with this condition had a faecal odour resembling that of wounds infected with the gas bacillus, but other men's socks, including my own, had the same odour, though there was no trace of trench foot. The smell was to be ascribed to the multiplication in the socks of organisms which got into the boots with the liquid mud.

Rubber knee boots were then issued to the men, and attention was paid to the socks being clean and dry. Rubbing the feet was persevered with both with antiseptic grease and whale oil. In addition, whenever possible, the men were given exercise. Yet, though the men's feet were saved from coming in contact with this liquid mud, still the incidence of "trench foot" did not abate.

It was at about this time that an article was published in the BRITISH MEDICAL JOURNAL ascribing a microbic cause for "trench foot." Interesting as it was, it was apparent now to me that bacteria were not the cause of the condition, and it was evident that the cause must be looked for in some other direction.

As times were now hard in the trenches, I thought of fatigue and consequent collection of waste products of metabolism in the cellular tissues of the lower extremities. This was very possible under the then existing conditions. It seemed reasonable to suppose that fatigue with stagnation of products of katabolism in the lower extremities might act as a predisposing cause, and cold and wet as the exciting cause. The symptoms and onset seemed to fit with this view, and a scheme on new lines was instituted. Hot soup, made from the bones of the fresh meat issued together with meat-extract cubes and vegetables, was sent up to the men in the trenches each night. The fresh meat was cut off the bones at the transport lines, passed through a mincing machine, and was, with the service biscuit, made up into most appetizing rissoles. These were cooked in the transport lines and sent up to the trenches, where they were heated up by the men in their mess tins. All suet fat was saved, and this, with flour and raisins bought from the profits of the dry canteen, was made up into plum-duff, which was exceptionally palatable and of high caloric value. On other days, where mutton had been an issue, Irish stew was made, and small suet dumplings included in it. It was served hot to the men in the trenches.

I will not go into the daily menu arranged by the commanding officer for the men, beyond saying that the rations were made most appetizing and were used to the last calorie; nothing was cast aside, the profits of the dry canteen being used to buy vegetables, flour, raisins, etc., by which means every particle of fat was turned to useful purpose. The soup made from the bones, etc., was excellent and was served most nights in the regimental head-quarters mess.

With this feeding the health of the men improved. There was less sickness; in fact, sick parades were for men in the trenches, under the conditions then existing, extraordinarily small, and incidentally the number of cases of trench foot began to fall. At this time an issue of long rubber boots had been made, and the men's feet were protected from trench mud, though not from wet, as socks got wet owing to condensation in the boot. The fact, however, remained that the number of cases of "trench foot," Stage II, fell.

This suggested that by an improvement in the general health of the men, by giving stimulating hot drinks at night with a rum issue at stand-to in the morning, and by the wearing of long rubber boots, we might hope to get rid of the condition entirely.

In this we were again disappointed, for though the number of Stage II cases fell almost to nil, yet a number of men paraded with painful swollen feet, that is Stage I, though their number was smaller than formerly. They were sent to hospital, and returned at the end of ten days, only frequently to relapse again. In the end those men who showed tendency to relapse were given employment further back, where they could turn in at nights, and under these conditions the trouble did not seem to recur.

We left that portion of the line at the end of the year, and went to another part where the trenches were in good condition, and were deep, so that men could move about during the day time. The weather, however, was bad, with much snow, frost, and wet.

I was doing my round of the trenches the first night we got in, and incidentally stopped to rest on the fire-step with my legs hanging down. I was surprised to find that at the end of three minutes my feet had "gone to sleep," there was the sensation of pins and needles, and the feet felt numb. Thinking this might be a coincidence, I tried it on two successive occasions, only to find the same thing happened each time. After the third time my feet in the morning were tender, and decidedly swollen, so that I could not get my boots on. I stayed in my dug-out the next day with my legs raised, and had my feet rubbed frequently. At the end of forty-eight hours all swelling and pain had gone. This experience caused me to go round at night and insist that when men were on duty in pairs the man whose turn it was to rest should lie with his feet up on the fire-step. Every man had a blanket; so that each man resting had two, his own and that of his acting partner. By this means every man resting did so with his feet up, and he had his great-coat and two blankets to cover him.

It was a pleasant change to see these men sleeping, and to find that they were warm and comparatively comfortable.

Though the weather we have experienced in the trenches has been most inclement, yet since taking this precaution we have had no cases of trench foot over a period of twelve days in the trenches. This is not a coincidence, I think; the unit which occupied the same trenches before us had several cases.

From the accompanying illustration it will be seen how congestion of the feet may readily be brought about by a man sitting on the fire-step and going to sleep. The sharp edge of the fire-step can exert considerable pressure over the popliteal space, and so impede the return of blood along the popliteal vein, without stopping the flow along the popliteal artery, and the soldier who is not on duty will invariably go to sleep sitting on this step, unless he is watched and warned to the contrary.

From the results and observations in the trenches, I have come to the conclusion that two factors are at work in producing trench foot:

1. A predisposing factor, namely, fatigue.
2. An exciting factor which is purely mechanical, namely, venous stagnation and consequent exudation of material into the tissues of the foot.

The condition may be classed in three stages, as follows:

Stage I, or the stage of congestion, brought about by resting, especially after any exertion or long standing, with the legs down. This is brought on more quickly if fatigue is in any way present, as after long standing while on sentry-go, when the lower extremity contains waste products of katabolism, so facilitating exudation from the capillaries into the connective tissue spaces. It will easily be seen how sitting on a fire-step, with the legs hanging down, would favour this, specially where there is some pressure exerted on the popliteal vein. The symptoms of Stage I have already been alluded to.

Stage II, or the stage of coagulation. Here the exuded material appears to have undergone coagulation. This, again, would be hastened and favoured by the presence of toxic katabolic products in the intercellular tissues. The feel of the foot in this condition, like to that of a solid india-rubber ball, coldness, and loss of sensation, marks some radical change between this stage and Stage I. Further, ordinary rubbing and massage seems to have but little influence on this condition, and electric vibratory massage combined with effleurage seem to be the only agents for removing the exuded material.

Stage III, or the state of gangrene, is brought about by the pressure of this exuded material on arteries and veins. There is thrombosis in the smaller venules, and such would be hastened by the presence of toxic katabolic substances present.

TREATMENT.

The whole plan of treatment aims at prevention. If once the condition has progressed to Stage II, then the case necessarily passes out of the hands of the regimental medical officer, and colleagues further down the line can better speak of the

treatment of the condition than I. The same applies to cases that have progressed to Stage III.

What concerns us who are working in the front line is prevention and the treatment of Stage I, which is the stage of congestion.

Prevention is attained by insisting, whenever possible, that the men while resting should do so with their legs elevated. This cannot too strongly be impressed on officers commanding battalions, the second in command, and especially company and platoon officers. In addition to this, a nightly tour of the trenches, to convince oneself that such recommendations are being carried out, is essential. A daily tour is not necessary from this point of view, as most of the men are sleeping in their dug-outs in the recumbent posture.

One blanket per man should be insisted on, so that the sentry resting at night on the fire-step has two blankets to roll himself in and lie with his feet up on the step.

Hot soup and rum ration are, in my opinion, valuable assets for the general vitality in trench life; and other little alterations in the method of serving up the daily ration have already been referred to. Attention to this is all-important in warding off fatigue.

These points seem small and perhaps tending to "spoil the soldier," but, in my experience, they are thoroughly appreciated and call forth better spirit and better work, and have done much to ward off fatigue.

Rubbing of the feet does no harm and may do good, but the good, I think, comes from the fact that the men change their socks after doing it.

Let me here repeat that the main points in prevention are:

1. Keep the feet raised whenever possible so as to prevent stagnation, especially after a period of standing while on sentry-go or in a listening sap.

2. Keep the soldier fit by getting the full calorific equivalent out of his ration, thus keeping the blood pressure up and "warding off fatigue."

If congestion (Stage I) has occurred, I have always detained the men at the regimental aid post for twenty-four to thirty-six hours. If a regimental aid post has not existed in the part of the line to be held I have immediately made one, and have always been supplied with a fatigue by the commanding officer to erect it in minimum time. This dug-out will usually accommodate six to eight men, and timely massage with rest have rendered the men fit to go back to trenches in thirty-six hours. They report each day for three days for further massage, and at the end of this time, with instructions as to the keeping up of their legs whenever possible, I have had no further trouble.

By this means many men were kept in the firing line who would otherwise have been temporarily lost to the unit, and this is a point the importance of which need not be emphasized.

I have to thank my commanding officer for the kind help and co-operation he has shown in this endeavour against "trench foot," and I have every confidence that we shall be able to face another winter campaign with a minimum of men going down with this condition.

The remarks and suggestions made in this paper may not be new to many, but what I have written has been the result of careful and persistent investigation of my own cases, which at first were considerable in number, but which have, I am glad to say, been reduced to nil.

THE EXCYSTATION OF ENTAMOEBA HISTOLYTICA (TETRAGENA) AS AN INDICATION OF THE VITALITY OF THE CYSTS.

BY

W. J. PENFOLD, M.B., H. M. WOODCOCK,
D.P.H., D.Sc.

(From the Bacteriological Laboratory, the King George
Hospital, Waterloo, S.E.).

AND

A. H. DREW,

BACTERIOLOGIST, ROYAL INSTITUTE OF PUBLIC HEALTH.

In the course of an experimental investigation undertaken to ascertain the value of emetine as a prophylactic for amoebic dysentery we have found kittens extremely refractory to the cysts of *E. histolytica* (*tetragena*)—that is, only a very small proportion (one out of twelve, after a three weeks' incubation period) of those fed with faeces containing large numbers of cysts become infected. We were thus led to endeavour to cultivate the *Entamoeba* from the cysts in order to obtain, if possible, stock cultures of active forms for rectal inoculation. Owing to the fact that we are going abroad very shortly, this work has now to be broken off for the time being. As we have found a method of causing the cysts present in the faeces to excyst and liberate the contained *Entamoeba*, we think it worth while to indicate briefly the results obtained, since this method furnishes the most reliable, and, indeed, the only conclusive, evidence of the vitality of the cysts. This is a point of the utmost practical importance as bearing upon the duration of life and the infective power of the cysts under varying environmental conditions.

A sample of faeces containing a good infection with cysts is well emulsified with saline (or water) and filtered through three or four layers of fine gauze, to remove the larger faecal particles. The filtrate is then centrifugalized and the deposit washed three or four times, the supernatant liquid, which contains large numbers of bacteria but no cysts, being pipetted off each time. By this means toxic products are removed and the cysts are concentrated in a mass of fine faecal debris. As excysting agents we have tried pepsin, in an acid medium, bile, and pancreatic extract, either alone, consecutively, or together, as appeared indicated, but the only success we have had has been with pancreatic extract used alone. The preparation used is Benger's *liquor pancreaticus*. A mixture is made

up in the following proportions: Nutrient broth 5 parts, liquor pancreaticus 2 (or 3), cyst-containing sediment 1 part. This mixture is then incubated for five to seven hours at 37° C. At the same time a drop of the mixture is placed on a slide, covered, and the cover-slip ringed to prevent evaporation; this is also incubated. This observation-preparation serves as a control to the tube and can be taken out and rapidly examined whenever desired, to ascertain how excystation is progressing; after five or six hours excystation is usually taking place.

Even of cysts in freshly passed faeces, the majority of which appear quite normal, only a small proportion excyst. The first indication of approaching excystation is that the protoplasm becomes very slightly retracted from the cyst-membrane and appears somewhat crinkled (Fig. 1). By careful watching it can be seen that the contour of the body is very slowly changing its shape, that is to say, the *Entamoeba* is becoming slightly amoeboid (Figs. 2, 3). The nuclei are not visible; it may be pointed

out that when the nuclear rings are clearly visible in a fresh *tetragena* cyst, it is a sign that the cyst contents are dead; in this respect the *tetragena* cyst differs from the cyst of *E. coli*. Next, the periphery of the body becomes applied to the thin cyst membrane in the region where the wall is about to be dissolved (Fig. 4). Dissolution of the cyst-membrane takes place over a small area only. It is brought about, we consider, by the action of external influences; for example, the pancreatic juice, probably helped to some extent also by bacterial ferments present in the intestinal contents.

In the next stage (Fig. 5) the *Entamoeba* is beginning to emerge from the cyst. A small protuberance, often finger-like, is thrust out through the aperture; it may appear clearer than the bulk of the protoplasm, and be

mainly ectoplasmic in character. The whole of the protoplasm now gradually flows out of the cyst (Fig. 6); the entire process of emergence may take only about ten minutes, though it may take longer. In every instance which we have observed, the entire protoplasm comes out as a single *Entamoeba*; there is no indication whatever of division while still inside the cyst. We are strongly of the opinion that this is the normal method of excystation. It may be mentioned that tyrosin was always present to saturation in the liquor pancreaticus which we used, the white deposit which is usually seen at the bottom of a bottle of this preparation (after keeping for a while) consisting of pure tyrosin needles and sheaves which have crystallized out. We are informed by Dr. Maclean that the amount of this amino-acid normally present in the duodenum is not likely to represent a greater concentration than we have

Excystation of *Entamoeba histolytica* (*tetragena*); from sketches made at the time of observation. Figs. 1, 2, and 3. Slight amoeboid changes within the cyst. Fig. 3 shows a slight development of ectoplasm (this is unusual, and only seen if excystation is apparently delayed). Figs. 5 and 6. Emergence of the *Entamoeba* through an aperture in the cyst membrane. Figs. 7 and 8. Two liberated *Entamoebae*, with their empty cysts (seen in optical section): in the latter figure the aperture in the membrane is in focus, and this *Entamoeba* possesses a "chromidial block" (the endoplasm is dotted to indicate its finely granular character; the ectoplasm is left clear).

used in our tubes. From our observations we do not consider that a division into four amoebulae takes place, as a rule, within the cyst. After the *Entamoeba* has completely emerged, the cyst-membrane left behind appears like a very delicate, single-contoured, usually spherical ring (Fig. 7); only by careful focussing at a particular level can the break in the wall be made out, which represents the dissolved area (Fig. 8).

We have seen excystation of amoebae which had no chromidial block in the protoplasm (Fig. 6), as well as of others which possessed this structure (Fig. 8); so that one of these conditions cannot be said, apparently, to represent a riper phase, as regards readiness for excystation, than the other. For a little while the liberated *Entamoeba* remains more or less rounded and sluggish; but soon it begins to throw out the typical clear, blunt pseudopodia of the *histolytica* type, these often welling out laterally in the characteristic manner. We have not yet been able to carry out direct observations further at this period, and cannot say, therefore, whether the *Entamoeba* proceeds to divide into four, and, if so, how soon this occurs. Indeed, from our living observations, we could not tell whether the amoebae which excysted had always four nuclei, or whether individuals with only one or two nuclei also had been able to excyst.

When we have ascertained that excystation was proceeding actively in the tubes, we have always subcultured from them into the expression-liquid of blood-agar tubes, to which either two parts of citrated blood or equal parts of citrated blood and fresh serum were added. These new tubes were then placed in a vacuum and incubated at 37° C. At from eighteen to twenty hours after the excystation period we have seen both small and moderate-sized active *histolytica* forms in these cultures, a few of the larger individuals containing red blood cells. It is a moot point whether any multiplication had occurred, beyond probably division of some of the originally encysted forms into four; and even in regard to this we do not feel certain. In spite of all our efforts so far, the growth of bacteria has always been excessive and gave no promise of successful cultivation of the *Entamoebae*. On one or two occasions, twenty-four hours later—that is to say, from forty-two to forty-four hours after excystation—we have found one or two amoebae still alive but moribund.

To our surprise, the above method, which has proved so successful for the excystation of *E. histolytica*, has entirely failed to produce excystation of *E. coli*, and by none of the other methods tried have we been able to induce this form to excyst. We have evidence, however, that the small "minuta" form, which we have recently described,¹ excysts in the same manner as *histolytica* (tetragena), using the same method; and this bears out our view as to the close relationship of these two forms.

In the case of *Lambliia*, also, we have been unable to induce excystation. From the appearances of the cyst contents which we have observed, we are strongly of opinion that only a single individual will be liberated and not two separate individuals. In other words, we consider, as we have previously stated,² that conjugation and not division occurs within the *Lambliia* cyst. Wenyon³ has expressed the view that these cysts are multiplicative, and represent, indeed, the endogenous form of multiplication shown by these parasites within the host. In our opinion this view is mistaken, and does not take into account the biological factors (environmental conditions) which influence both encystment and excystation (Cropper and Drew,⁴ Woodcock and Lapage⁵). Not to enter into details here, we will only point out that when permanent (resistant) cysts, such as are passed out with the faeces, are formed in the bowel, conditions other than those prevailing in the region where encystment is occurring are necessary for excystation and the commencement of a fresh cycle of activity. Equally as is the case with the cysts of the parasitic *Entamoebae*, for instance, we have little doubt that these *Lambliia* cysts only undergo excystation on passing down the alimentary tract of a fresh host and coming into contact with its digestive juices. From our experience of multiplication in flagellates we should say the process takes place very rapidly; and it is quite likely that it occurs mainly amongst those parasites which are attached to the epithelium.

Had time permitted we had intended to use the above described method of inducing excystation of the cysts of

E. histolytica to test the vitality, and consequently the infective power, of the cysts, when kept under different conditions for varying lengths of time; much more evidence is needed in regard to this point on account of its great hygienic and sanitary importance. The chief experiment which we have had opportunity to carry out, so far, in this direction has been to keep cysts in a very slowly running current of water for fifteen days and to ascertain that certainly some were still alive at the end of this period. By this time the debris was practically freed from faecal bacteria, apart from those normally occurring in the water, and free-living protozoa (ciliates and flagellates) were present. We should say, therefore, that water which has been contaminated with cyst-containing faeces may remain a source of infection for a considerable period.

AMOEBIC DYSENTERY IN A MAN WHO HAD NEVER LEFT ENGLAND.

BY

C. WORSTER-DROUGHT, M.B.CANTAB.,

TEMPORARY LIEUTENANT R.A.M.C.,

AND

D. D. ROSEWARNE, M.R.C.S.ENG., L.R.C.P.LOND.,

TEMPORARY LIEUTENANT R.A.M.C.,

ATTACHED TO BACTERIOLOGICAL LABORATORY, ROYAL HERBERT HOSPITAL.

AMOEBIC DYSENTERY occurring in the British Isles is remarkably rare. Most of the cases hitherto recorded have been conditions of intestinal ulceration associated with liver abscess which have only been diagnosed *post mortem*. Thus Dickinson,¹ in 1862, described the occurrence of a hepatic abscess of considerable size with ulceration of the large intestine in a woman who had never been out of England. In 1881 Dickinson² again recorded a second case, that of a man aged 36, who also had never left England. *Post mortem*, ulceration of the large intestine was found coexisting with a liver abscess. In the same year Moore³ described a further case, that of a child aged 3½, who died with two hepatic abscesses and extensive ulceration of the large bowel. She had never been out of London. Amoebae are not mentioned in connexion with any of these cases, though the organism is said to have been discovered by Lamb in early as 1859, subsequently being more fully described under the name *Amoeba dysenteriae* by Lösch in 1875.

Saundby and Miller,⁴ however, in 1909 recorded the case of a man aged 42, in whom, *post mortem*, were found extensive ulceration of the large intestine and a liver abscess. Amoebae were demonstrated both in the intestinal ulcers and in the abscess cavity.

In none of these cases was the diagnosis made until after death, and it remained for Marshall,⁵ in 1912, to report the first case occurring in the British Isles which was diagnosed during life. This was a man who had never left Scotland, and in whose stools amoebae were repeatedly demonstrated; he made a good recovery. An ex-soldier, living near this patient, had spent some time in India, but gave no history of dysentery. Amoebae were not found in this man's faeces, and feeding experiments on a cat gave negative results.

Our patient was a private, who enlisted at the beginning of 1915. Prior to enlistment he had always lived in or about Manchester. The great majority of the men in his unit had been abroad at some time, but none had been out of England during the present war. Of three men who were sleeping in the same room as the patient only one had been abroad. This man had served in the South African war, where he had had diarrhoea of three days' duration only, which never recurred. His faeces, as well as those of five others in the unit, including the cook, who were said to have had dysentery abroad some years ago, were examined, with negative results. One, however, showed encysted forms of *Entamoeba coli*.

The patient, rather a stout man, aged 39, but looking considerably older, was admitted to hospital on February 16th, 1916. He had had no previous illness up till the onset of his present

complaint. Ten days before admission he complained of slight abdominal pain which increased in severity. Diarrhoea did not commence until four days later; from that time the number of motions varied from six to twelve per day, and were associated with some degree of tenesmus. It was not until the fourth day of diarrhoea (two days before admission) that he noticed "blackish blood" in the stools, and from this time onwards they continued to be blood-stained with an average of about twelve in the twenty-four hours.

On admission the temperature was 99° F., and the pulse 80. The tongue was furred, the teeth discoloured and carious, and he complained of pain across the lower part of the abdomen. There was marked tenderness in the left iliac region, and also to the right of the umbilicus, but no rigidity of the abdominal wall. The liver and spleen were not enlarged, and nothing was felt on rectal examination. The faeces were dark in colour, and contained mucus and dark red blood. A microscopical examination of the motion the following day revealed the presence of a large number of *Entamoeba histolytica*.

On the patient's fourth day in hospital emetine treatment was commenced. One grain of emetine hydrochloride was given by hypodermic injection daily for fourteen days (one-third of a grain in the morning and two-thirds of a grain at night).

During the first three days after admission the number of motions averaged twelve in the twenty-four hours; they were quite loose, and contained a quantity of blood and mucus. After six days of emetine treatment the number of motions had fallen from twelve to four in the twenty-four hours; they were still loose, and contained mucus but much less blood. Three days later the motions had diminished to three a day; they were loose, but there was only a small quantity of blood, and the patient was feeling much better. On the twelfth day with emetine the motions, though still inclined to be loose, were free from blood, and for the first time amoebae were absent. On the last day emetine was given the patient had but one motion, semi-solid, with a little mucus but no blood. Five days later the motion was fully formed, and mucus and blood were absent. From this date the patient progressed favourably without further incident.

The faeces were frequently examined throughout the illness, and active forms of *Entamoeba histolytica* were found up till the tenth day of treatment with emetine, but at no time afterwards. No cystic forms of the parasite were ever seen, although the motions were examined until three weeks after the patient's recovery, and no bacilli of the typhoid-dysentery group were isolated.

The blood tested as regards agglutinating power against the dysenteric organisms "Shiga," "Flexner," and "Y" types, proved negative.

The tongue, which was furred from the beginning, continued so until about the seventh day with emetine injections, when it began to clear. It was quite clean when they were stopped. The liver was frequently examined, but at no time was any enlargement noted. Abdominal pain persisted with diminishing severity until, practically, the motions were fully formed. During the first ten days in hospital he frequently complained of considerable pain after defaecation. The tenderness to the right of the umbilicus, mentioned on admission, had quite disappeared by the ninth day of emetine treatment, while that in the left iliac region did not disappear until three days after the motions were quite normal.

As regards temperature, at no time was it above 99.4°, which point it frequently reached during the first ten days after admission, but from this time onwards it was normal.

Although we failed to find pathogenic amoebae or their cysts in the faeces of those men examined, it is possible that the carrier was among other men in the unit who had been transferred to duties elsewhere before the patient came under observation.

The case we have recorded, therefore, appears only to be the second reported as occurring in Britain in which amoebic dysentery was diagnosed as a primary condition, and during life.

SIXTEEN cases of plague have been notified in Hong Kong since January 1st.

The *Boston Medical and Surgical Journal* states that it has been computed that there are now more than two hundred open-air schools and classes for tuberculous and anaemic children in the United States. Massachusetts heads the list with 86, of which 80 are in Boston; next come New York with 29 and Ohio with 21. The first school of this kind was opened in 1907, and in 1910 there were only thirteen at work. It is estimated that there should be in cities one open-air school for every 25,000 of population.

THE TREATMENT OF PUERPERAL SEPSIS BY UTERINE SUCTION AND DRAINAGE.

BY

NORMAN PORRITT, M.R.C.S., L.R.C.P. LOND.,

CONSULTING SURGEON, HUDDERSFIELD ROYAL INFIRMARY.

THE suction tube has all the advantages with none of the dangers of the uterine douche. In at least two cases I have seen the uterine douche convert a smart sapraemia into a rapidly fatal general infection, whilst in another case it set up acute, presumably chemical, peritonitis. Whilst I was administering the douche the woman was seized with agonizing abdominal pain, which was quickly followed by general collapse and rapidly developing abdominal tenderness and distension. The douching was at once stopped, but the patient died five hours after the onset of the acute pain.

Dr. Goodall¹ has collected sixteen examples of chemical peritonitis following intrauterine douches. He says:

My eyes have been opened recently to the great ease with which fluid can be forced from the uterine cavity into the peritoneum. This was first brought to my notice by the frequency with which watery fluid was found in the peritoneal cavity after curettage. In not a few cases I have been astounded at the amount, and have examined the uterus for evidence of puncture, but this was never found. But the condition was readily explained when, later, Dr. Chapman began to inject a strong solution of iodine into the uterus in carcinoma cases in order to kill out the malignant cells and prevent their contaminating the field of operation. It was then found that, though a minimum of force was used, invariably the pelvic peritoneum was deeply stained, and contained fluid iodine in variable quantity.

To illustrate the patulousness of the Fallopian tubes Dr. Goodall narrates a case of congenital atresia of the sigmoid. The abdomen was markedly distended, and dark liquid blood was coming in spurts from the vagina. On operating, the abdomen was found full of blood and meconium, the sigmoid having ruptured. At the autopsy, four hours later, blood was still coming from the vagina.

In the cadaver Dr. Goodall has injected methylene blue into the uterine cavity with douche-can and cannula, imitating as closely as possible the technique of operative work. With a pressure of only two feet of elevation, and in some cases only eighteen inches, and with a temporary obstruction to the outflow, such as is frequently caused by clots and fragments of tissue, he was able to send fluid into the peritoneal cavity through the Fallopian tubes. Hence, he says, the risk of chemical peritonitis, not to speak of septic peritoneal contamination.

Then it should be possible to remove retained decidua from the uterus by means of the suction tube, and obviate the need for the deadly curette and the dangerous digital exploration of the uterus. The method of treatment is illustrated in the following cases:

CASE I.

On August 4th, 1914, I was asked to see a primipara, aged 25 years, who nine days before had been attended by a qualified midwife, who is also a trained hospital nurse. The labour was normal, and the placenta came away intact in about twenty minutes. When I saw the patient she had a temperature of 103.8° and a pulse of 140. The lochia had been and were normal and odourless, but the large uterus was retroverted. The uterus was reduced and a saline ordered. Next day, after vaginal douching, a gauze drain was put into the uterus, and renewed daily. For three days the temperature hovered round 103°, the patient was apathetic, semidelirious, had intense headache, there was some abdominal distension, and the lochia became fetid. On the thirteenth day after delivery a glass Budin's catheter, to which the inlet end of a Higginson's enema syringe was attached, was passed into the uterus. To secure the syringe to the Budin's catheter the inlet valve was removed. The tube of the syringe between the bulb and the catheter was held firmly and the bulb squeezed, so as to drive out the contained air through the nozzle. On releasing the pressure on the bulb, the valve behind the nozzle closed and prevented the return of the air. There was then a vacuum in the syringe, and on releasing the pressure on the tube, between the bulb and the Budin's catheter, suction was exerted through the catheter within the uterus. No air was drawn into the uterus, although the suction drew into the orifices of the catheter thick, grumous, semipurulent masses, which were too big to pass through, and, when the catheter was withdrawn, came with it. Reintroduction of the catheter and suction drew out more of these thick pieces. The vagina was syringed, and a gauze drain was inserted into the uterus. The next day the patient was free from headache, and the temperature had fallen to 100.8°. The fetor of the discharge was less, though the labia were swollen and red, and an abscess with no well-

defined limits formed over the sacrum. This was incised later. Suction was applied to the uterus on two successive days, after which the temperature did not rise above 99°, and the patient made a good recovery.

CASE II.

I was called to a primipara, aged 21, on January 6th, 1915. Just before my arrival she had given birth to a dead, decomposing six or seven months child. The placenta came away intact whilst I was separating the child. No vaginal examination was made. The same night the temperature was 99.4°, the next night 101.2°, and on the following morning 103°, with a pulse of 140. The vagina was douched night and morning, and Budin's catheter passed into the uterus. On suction by means of the Higginson syringe thick debris filled the tube and was brought away, after which a gauze drain was left in the uterus; 3 grains of calomel were given. The temperature at night was 100.8° F., pulse 120. There was no abdominal distension. The lochia were most offensive, and the smell was intensified when the gauze drain was taken out of the uterus. The suction tube was passed daily, and a gauze drain left in the uterus. On January 13th there was some odourless discharge on the diaper, and the smell in the room was only just perceptible. As soon, however, as the catheter was passed into the uterus it filled with thick, dirty, bloody liquid, smelling most offensively. About an ounce and a half of this offensive material, together with a quantity of blood clot, were sucked out of the uterus. On the next day, although there was only a little almost odourless discharge on the diaper, a quantity of thick fetid red liquid was evacuated from the uterus.

On the next day there was a similar experience. Though the diaper was covered with more discharge, free from offensive smell, thick, foul-smelling liquid was obtained from the uterus. The temperature, which for the last six days had not been above 101° at night, now reached 102°; the pulse was 120. As there was evidently imperfect drainage from the uterus, a piece 3 in. long was cut from the end of a large size celluloid Budin's catheter, and, held in a pair of forceps, was passed into the uterus. A string was attached to the piece of catheter for withdrawal, and the tube was retained in the uterus by a gauze vaginal plug. The tube was removed, sterilized, and reinserted daily. In two days the temperature fell to normal, and as it was normal on the following day, and only a small quantity of odourless, glairy mucus was obtained on suction of the uterus, a gauze wick was substituted for the celluloid drain. The next day the temperature rose to 100°, and as some thick, grumous liquid, very like thick pus, together with mucus and blood came away, the celluloid tube was reinserted into the uterus. The same night the temperature dropped to normal, and, next day, though nothing could be sucked out of the uterus, the gauze in the vagina, as well as the diaper, were soaked with discharge. Evidently the uterus was draining well. The temperature remained normal for three days after the reinsertion of the tube, and it was then removed and no drain of any kind was put into the uterus. The same night the temperature rose to 102°, and the patient had a rigor. It was found impossible to insert the celluloid tube into the uterus, which was acutely anteverted, but the next day after softening the tube in hot water and bending it, it was inserted without difficulty. It remained in the uterus forty-eight hours, when it was finally removed, and as tender peritumescence thickening became perceptible, and as it was impossible for the girl to remain longer where she was, she was removed to the Liverpool Hospital for Women. The peritumescence subsided satisfactorily, and the patient left the hospital in nine days.

I was not aware when I drained this girl's uterus, by placing a tube within it, that the same thing had been done before. Mr. H. Milton¹ has drained the puerperal uterus, keeping the tube in the uterus six, ten, and fourteen days; whilst Dr. Ernest Gallant,² of New York, has reported 252 cases of continuous uterine drainage in non-puerperal cases. The tubes were worn in the uterus without removal for so long as five, six, and seven months. The results of Mr. Milton and Dr. Gallant suggest that I need not have removed the tube from my patient's uterus so soon after the temperature fell.

The following is another case in which similar principles were adopted:

CASE III.

Mrs. E., aged 30. The child was born just before I arrived at the house, and the placenta was easily expelled intact in about four minutes. No vaginal examination was made, but three stitches were put into the perineum. In an adjoining room the patient's father was dying from an ulcerating epithelioma of the lips, face, and mouth. The stench from it filled the whole house. The day after the child was born the mother's temperature was 99.6°, on the second day 103°, after which it fell to 100°. The lochia became very offensive, the smell resembling closely that from the father's room. Till the seventh day vaginal douching night and morning was used, and then, as the temperature remained above 100°, Budin's catheter was passed, and a small quantity of offensive brown liquid was withdrawn on using suction. A gauze drain was passed into the uterus. The next day, on inserting the tube into the uterus, it filled at once with thick brown liquid, less offensive than before. The suction tube was used daily, and each day the fluid removed became less offensive,

less opaque and thick, until, at the end of five days, just a small quantity of clear, odourless, blood-stained fluid, free from shreds and semi-solid matter, was sucked out. After this the only local measure used was a vaginal douche night and morning. The condition of the patient, however, became more grave, though Dr. Wille³ of Liverpool, who kindly saw the patient with me, agreed that there was then nothing abnormal in or around the uterus. The clinical picture—profound anaemia, intractable vomiting, lethargy, intermittent abdominal distension and visible peristalsis, pigmentation of the breasts, legs, and abdomen—suggested Addison's disease. On the twenty-fourth day after delivery the patient died.

This case was one of true septicaemia, apparently, producing fatal blood destruction. The woman's father, whom I look upon as the source of the infection, died ten days after the birth of the child. I regret now that I did not give the woman antistreptococcal serum at the outset. But the first symptoms were not severe, and my experience of serum treatment in puerperal cases has been most disappointing.

Uterine suction tells us the conditions in the interior of the uterus. It is most instructive to watch the gradual alteration of the stuff withdrawn from a thick, offensive fluid, loaded with semi-solid purulent masses, to a clear red liquid, and from that to an inoffensive mucus. Moreover, it prevents us from being misled, as we doubtless often are, by the deceptive character of what we find upon the diaper. The diaper may be covered with discharge, which may be only an overflow, or may not come from the penthouse in the uterus at all, for there may be odourless discharge on the diaper, and foul, fetid fluid in the uterus. And efficient drainage of the uterus is the key to the successful treatment of puerperal sepsis.

The holes in the uterine end of the ordinary Budin's catheter are too small, and Messrs. Down Bros. have made to my instructions a larger model, which will allow the passage of uterine debris into the catheter. They

have also made for me a grooved celluloid drain for intra-uterine use, when the use of a drainage tube is indicated. Syringes other than the Higginson could be used to exhaust the suction tube, so long as they do not pump air into the uterus.

My cases are not numerous enough to dogmatize upon, but as now my opportunities for seeing such cases are limited I venture to publish them.

A NOTE ON THE USE OF THE GALVANOMETER AS AN AID TO THE DIAGNOSIS OF NERVE LESIONS.

By G. NEPEAN LONGRIDGE, M.D. VICT.,
F.R.C.S. ENG., M.R.C.P. LOND.

SOME two years ago an article appeared in a medical periodical dealing with the electric currents which could be detected in the human body with the aid of a sensitive galvanometer. From the results obtained it was surmised that the brain is the seat of generation of an electro-motive force which is carried to the tissues by means of the nerves. Being sufficiently interested I put myself into communication with the author of the paper, and found that Mr. A. E. Baines, a submarine cable electrician, was the author of the theory. After some correspondence and interviews with this gentleman I obtained and set up an extremely sensitive astatic galvanometer of the Kelvin type. The instrument I am using has a resistance of 99,000 ohms.

Recently I have had an opportunity of examining two cases which, to my mind, constitute definite proof of the main truth of the theory. The examinations were made in a room at least half a mile away from the tram lines in the town which carry a continuous current of 500 volts, and in all cases the precaution was taken of earthing the patient before the readings were made. The method used was to fix a circular silver plate about an inch in diameter in the exact centre of the forehead; this plate

was connected to one pole of the galvanometer. The second pole was connected to a small silver button 2 mm. in diameter mounted in a vulcanite handle which could be brought into contact with any part it might be desired to test. With both poles in contact with the patient's body and the circuit key closed a deflection was obtained on the galvanometer scale which could be read off in millimetres.

The first case was that of a soldier under my care in the Racecourse Hospital, Cheltenham, with a wound just below the centre of the left forearm, and definite symptoms of paralysis of the median nerve below the seat of the injury. The wound had been inflicted several weeks before I saw him, and had healed.

On examination with the galvanometer the following deflections were obtained on the dates indicated, the moving contact being pressed upon the pulp of the fingers:

Galvanometric Deflections Obtained in Two Cases of Injury to Nerves.

	CASE I.—Wound of Median Nerve.				CASE II.— Wound of Ulnar Nerve.
	First Examination.	Feb. 21st.	March 15th.	April 1st.	April 1st.
Thumb ...	20 mm.	0 mm.	0 mm.	5 mm.	320 mm.
First finger ...	0 mm.	0 mm.	0 mm.	55 mm.	Off scale deflection.
Second finger	0 mm.	0 mm.	6 mm.	120 mm.	Do.
Third finger ...	75 mm.	90 mm.	130 mm.	Rapid off scale deflection 100 mm.	Do.
Radial side...	5 mm.	7 mm.	5 mm.		Do.
Ulnar side ...	155 mm.	140 mm.	150 mm.	Rapid off scale deflection Do.	3 mm.
Fourth finger	120 mm.	150 mm.	135 mm.		5 mm.
Hypothenar eminence	—	—	—	—	0 mm.
Thenar eminence	—	—	—	—	Off scale.

On February 18th, a few days after the first examination, I dissected out the median nerve, which was embedded for 1½ in. in dense scar tissue, and was partially divided on the ulnar side. After freeing the nerve from the scar tissue I resected three-quarters of an inch of it which was densely fibrosed, and joined the ends by catgut sutures. At the suggestion of Dr. Affleck, who was assisting me at the operation, I wrapped a piece of vitelline membrane from an egg round the seat of the suture. The wound healed moderately well, with the exception of a small area in the centre where the incision went through the old scar.

On April 1st the deflections obtained were better. On this occasion the man had walked a distance of two miles to the testing room, whereas on previous occasions he had been brought in a motor. The warmth of the day and the exercise perhaps accounted for the higher readings on this occasion.

In this case I have for the sake of simplicity only mentioned the finger deflections, although others were taken which were in consonance with the results obtained above.

On April 1st I was fortunate in being able to examine a man (Case II) with a healed wound just above the internal condyle of the left humerus, which was thought to have resulted in division of the ulnar nerve. The deflections in this case were the exact complement of the previous one.

These two cases to my mind demonstrate that something—it may be electricity or it may be something else—which acts upon a galvanometer in the same manner that electricity does is conducted by the nerves. The first case also shows that anatomical continuity of a nerve does not imply also its vital conductivity, since three days after complete section and restoration of its anatomical continuity it was not conducting any current which could be demonstrated by the galvanometer. I might mention that no deflection is obtained as a rule from scar tissue which is generally devoid of nerve fibrils.

In this short communication I do not wish to go into any of the wider applications of the galvanometer as an aid to diagnosis but simply to establish the fact that the nerves obviously do conduct electricity or a "trophic influence," which is at present indistinguishable from it.

A SIMPLE PORTABLE REFRIGERATING BOX AND ITS USE AS A TEMPORARY INCUBATOR IN MILITARY WORK.

By S. DELÉPINE,

DIRECTOR OF THE PUBLIC HEALTH LABORATORY, UNIVERSITY OF MANCHESTER.

LAST autumn a large number of soldiers who had returned from the Near East were admitted to several of the hospitals forming part of the 2nd Western Military Hospital. Most of these men were reported as convalescing from dysentery, typhoid fever, and paratyphoid fever. The excreta of all these cases had to be examined repeatedly before the men could be discharged from hospital.

At first these examinations were conducted at the Public Health Laboratory by Captain Sellers and Captain Loveday, but during the month of December the temporary services of three other bacteriologists became available.

With regard to the typhoid cases, it would have been possible by an extension of the usual laboratory arrangements to examine daily a large number of cases, but as the faeces of the soldiers returning from the East had to be tested not only for the presence of typhoid, paratyphoid, and dysentery bacilli, but also for amoebae, it was desirable that the material should be examined while the stools were still warm, as this made the detection of motile protozoa easier and more rapid and certain.

It was, however, impossible to make arrangements to examine daily, immediately after evacuation, the stools of some 100 or 150 men, and it became necessary to devise means of collecting the material and keeping it warm for some time until the bacteriologist could conduct his examination.

It occurred to me that the portable refrigerators which are regularly used in the laboratory for the forwarding of samples of water, milk, and other products, would meet our requirements if used as warm chambers. These chambers allowed room for from thirty to sixty of the special tubes I have designed for the collection of samples of faeces for bacteriological purposes (see below). It seemed probable that the use of these temporary warm chambers would render the examination of a large number of specimens under suitable conditions not only possible but also convenient, and the experience gained in five months, during which more than 10,000 examinations of dysenteric faeces were made, has confirmed my expectations.

Description of the Portable Refrigerator.

The present form of the refrigerating box is a modification of a somewhat better but more fragile portable refrigerator, designed by me in 1892, and still in use both in my laboratory and elsewhere. The original box is a double-walled zinc chamber resembling a small incubator. The proportionally large cavity between the walls is filled with ice through a large lateral bunghole. The chief fault of this box is that its unsupported, comparatively thin walls suffer when the box is thrown about, as frequently occurs during railway transit. My new refrigerating box, which I have used for some years, is nearly as efficient as the first, and has great powers of resistance. It consists of a central or lateral metal ice-recipient, hermetically closed by means of a large screw bung. Round the ice-box a number of compartments are formed by metal partitions continuous with the walls of the refrigerating box. Each one of these compartments is

Portable Refrigerating Box (or Incubator).—The size of the box is 12 in. by 9½ in. by 8½ in. A, Recipient for ice or for warm water; B, screw bung for ditto; C, compartments for objects to be kept cool or warm; D, felt covering; E, wooden box; F, lid.

Round the ice-box a number of compartments are formed by metal partitions continuous with the walls of the refrigerating box. Each one of these compartments is

a tube of the same length as the refrigerating box. The bottom of these tubes may be closed by a metal plate or left open. Externally the refrigerating box and the system of compartments attached to it have the form of a cylinder, cube, or parallelepiped, as may be found most convenient. This part of the apparatus may be made of any metal, but on account of weight zinc and aluminium are the most suitable.

This metallic part of the apparatus is enclosed in a wooden box lined internally with a layer of loose felt $\frac{1}{2}$ in. to $\frac{3}{4}$ in. thick. To secure efficiency this felt should be quite dry, and to prevent any wetting taking place when the ice-box is filled, the opening of the box is at the bottom of a shallow tray, which must be mopped quite dry each time the box is filled. The felt may also be enclosed between layers of waterproof material. The capacity of the ice-box is 1,800 c.cm., and 1,000 grams of broken ice can easily be packed into it.

If in a room at 22° C. a bottle containing 250 c.cm. of water or milk at 15° C. is placed in one of the compartments of the refrigerator, and the wooden box is properly closed, the temperature of the water falls to 8° C. in one hour, to 4° C. in two hours, to about 2° C. in three hours, 1° C. in four hours, and remains below 2° C. for twelve hours more; it then rises gradually to 9° C. in another twelve hours. For at least eighteen hours the temperature of the water or milk remains below 4° C., and is sufficiently low to inhibit the growth of most bacteria.

In the case of water or milk at 36° C. the temperature is brought to about 8° C. in three hours, to below 4° C. in six hours, and continues to fall up to the fourteenth hour, after which it begins to rise slowly, but keeps below 4° C. for another ten hours.

No material multiplication of bacteria is observed in the course of twenty-four hours in a bottle of cow's milk placed in one of these refrigerators immediately after milking.

Peptone bouillon inoculated with a loopful of a culture of *Bacillus enteritidis* taken as an example of a very quickly growing organism, remains quite clear for over twenty-four hours when placed in a portable refrigerator; the same quantity of bouillon inoculated with the same amount of culture kept in a living-room at 18° C. is quite turbid after the same interval of time. In an incubator at 37° to 40° C. the growth of the bacillus renders the bouillon turbid in about four to five hours.

By removing daily the melted ice water and replacing it by fresh ice it is possible to keep the contents of the refrigerating box at a suitable temperature for several days when a large refrigerator is not available.

Description of Portable Temporary Warm Chamber or Incubator.

If the stoppered receptacle of the apparatus just described is filled with hot water or other material at a suitable temperature, capable of liberating heat gradually, a convenient form of temporary portable incubator is obtained. It is true that the temperature of products placed in this apparatus falls gradually and constantly, but this cooling takes place slowly, as is shown by the following observations.

The incubator being in a room at a temperature at 15° C., the stoppered receptacle was filled with water at 48° C. and a bottle containing 250 c.cm. of water at 34° C. was placed in one of the compartments of the apparatus. After two hours the temperature of the water in the bottle was 35° C.; after three hours it had returned to 34° C.; after six hours it was 30° C., and was still 20° C. fourteen to fifteen hours after the beginning of the experiment.

In another experiment, the temperature of the room being 15° C. and that of the water in the recipient 48° C., the cooling of 250 c.cm. of water placed in the incubator took place as follows:

The Original Temperature of the Water in the Bottle placed in one of the Compartments of the Incubator was slightly over 35° C.

After 1 hour	the temperature was about	...	37.0°
" 2 hours	"	"	36.7°
" 3 "	"	"	35.0°
" 4 "	"	"	33.5°
" 5 "	"	"	31.2°
" 6 "	"	"	30.0°
" 14 "	"	slightly below	20.0°
" 20 "	"	over	17.0°

At the end of 14 hours the temperature was still 5° above that of the air outside the apparatus refrigerator.

By filling the recipient with water at 55° to 60° C. a suitable range of temperatures, extending over a longer period, is obtained.

Practical tests gave results in accordance with the above findings. Peptone bouillon inoculated with one loopful of *Bacillus enteritidis* and placed in the portable incubator at 34° C. was nearly as turbid in five hours as a similar amount of bouillon inoculated with the same amount of *Bacillus enteritidis* and incubated at 36° C. in an ordinary incubator was found to be after the same interval of time.

After twenty-four hours the growth of the culture in the portable incubator had considerably increased, but, as could be expected, was somewhat less abundant than that of the culture kept during the same period at a constant temperature of 36° C.

With regard to intestinal protozoa, they remained motile in faeces contained in collecting tubes placed in the portable incubator while the stools were still warm—that is, for several hours.

The apparatus which I have devised for the collection of faeces consists of a deep round glass spoon a little over $\frac{1}{2}$ in. in diameter, provided with a long handle about 6 in. in length. This spoon is kept in a stout test tube, well closed with a cork through which the handle of the spoon passes. By means of this apparatus it is possible to take, with a minimum amount of inconvenience, suitable samples of the stools which have been passed into sterilized vessels provided for the purpose.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CANCER ORIS TREATED BY GALYL.

A GIRL, aged 3 years, was admitted to the Ham Green Isolation Hospital on February 4th suffering from measles and bronchopneumonia. She was a feeble, ill-nourished child. There was a considerable amount of stomatitis, and the upper incisors were much decayed. On February 22nd the right upper central incisor dropped out, leaving a necrotic socket. By the next day, in association with extremely rapid sloughing of the mucous membrane on the premaxilla, two more of the incisors came away. A sloughing ulcer was also forming on the buccal surface of the upper lip opposite the upper incisors. On February 24th the condition was as follows: The whole of the premaxilla was devoid of mucous membrane and obviously dead. The mucous membrane reflected on to the buccal surface of the upper lip was destroyed for an area about the size of a shilling continuous with the necrotic surface on the premaxilla, and a deep hole was punched out of the lip though not perforating it. The fetor was extreme. The temperature from the beginning of the illness was swinging up to about 101° F.

Under chloroform Major Robert Lansdowne removed the whole of the dead bone, including the last incisor and both canines, and the corresponding embryonic teeth.

Next day, as the destructive process was extending rapidly, 6 cg. of galyol were injected intravenously without producing any toxic symptoms. Within forty-eight hours a line of demarcation formed between the living and dead tissues. By February 29th granulations were growing up through the sloughing areas, and the fetor was much less marked.

The improvement was maintained until about March 17th, when the granulations and line of demarcation began to disappear. By March 19th the destructive process was obviously again extending rapidly. Another dose of 6 cg. of galyol was given intramuscularly, as the previous intravenous injection was found very difficult in a child of this age. On March 21st a clear line of demarcation had again formed, and from this date the cavity began to heal rapidly; some small pieces of dead bone separated. The intramuscular injection caused some localized tenderness, but no pain or swelling.

On April 12th the right upper molar, which was loose, was removed. By this date the child's general condition was greatly improved, and the mouth nearly healed. She was discharged on April 25th, with the mouth completely healed and the deep cavity covered by healthy mucous membrane. Her general condition improved to a remarkable extent during the last four weeks in hospital, and she became fat and well.

The fact that rapid improvement occurred after each

dose of the galyl seems to show that it was due to that drug. Eusol was used locally to the mouth throughout the whole course of the illness. It is, perhaps, pertinent to remark that the child had had no mercury or other drugs which might cause this condition during any part of her treatment.

B. A. PETERS, M.D., B.C., D.P.H. Cantab.,
Medical Officer, Ham Green Hospital and Sanatorium,
Bristol.

THE USE OF SOME SIMPLE THINGS IN SURGERY.

I FOUND the following useful:

1. "Cements" for the removal of foreign bodies from urethra—chiefly stone. Pass a full-sized endoscopic tube with round, not oblique, end, down to body and fix latter by finger behind it from the outside. Remove moisture by cotton-wool. Melt some "elastic glue" and dip the pen end of a pen-handle therein; quickly pass this down the tube and retain in contact with the body for some time. Withdraw tube and pen-handle together. In the only case I tried this it was successful. Cold externally would make the "cement" set better, and perhaps other things (pitch, etc.) might stick firmer still. Forceps nearly always tear the mucous membrane. The same device might be used for the ear.
2. A condom tied over a catheter, lubricated, passed and inflated, is useful for urethral or prostatic hæmorrhage. Perhaps likewise for epistaxis.
3. A wine or whisky bottle containing hot water, and kept pressed to the perineum for some hours, the night of the day an instrument is passed, very materially aids the absorption of stricture, and is much more striking than fibrolysin; containing cold water it is the best means of subduing the erethism of inflammation. It is efficient in pruritus ani.
4. An elastic bandage applied at proper time after a hydrocele is injected (iodine and carbolic acid), by keeping the layers of tunica vaginalis in apposition, will often lead to radical cure.
5. Tinct. iodi painted on the hands, over this tinct. benzoin. co., and over this iodine again, is no mean substitute for gloves.
6. *Extemporary specula, etc.* The handles of two toothbrushes are an excellent anal speculum; the loop ends of hairpins bent at right angles, good nasal. Two teaspoons bent back $1\frac{1}{2}$ in. from bowls make a bladder speculum. Dinner forks bent forward at prongs are the best wound retractors.
7. The end of a scalpel handle flattened more, rounded off, and serrated forms a much needed dissector (separating bladder, etc., from adhesions).
8. Any thick-walled small rubber tube cut very obliquely at one end, the edge of the ellipse being smoothed off by a heated knife blade, constitutes, when well lubricated, a capital catheter.
9. A whalebone stylet bent into coudée shape in hot water, and passed into this or into any rubber catheter, makes the best coudée catheter.
10. Bristle and wire pipe cleaners, pulled to and fro through catheters, are the best cleaners of their lumens.
11. A tuning-fork is useful in the diagnosis of fracture.
12. The air balloon of a small football under a T bandage and inflated by a cycle pump makes the most efficient perineal pressure, and above the pubis the best uterine. A child's stout air balloon makes a Petersen's bag.
13. A strip of lint tied round the root of the penis and embracing the scrotum behind the testes is the handiest contrivance to which to attach the threads of a retained catheter.
14. The hair of women in scalp wounds, after disinfection of the parts by iodine, can be used as sutures by tying bundles of the hairs together. As far back as my student days I used this (and with no more sepsis than with ordinary nodes) in Dublin, a city then distinguished for its lacerated scalps.
15. A stout stick under the bent knees, the ends connected to the top of the operating table by two bandages, does for a Clover's crutch.

Finsbury Pavement, E.C.

JAMES MACMUNN.

By decree dated February 24th, 1916, the Italian Government gave official recognition to the national workshop for the manufacture of artificial limbs and other prosthetic apparatus for wounded soldiers established at Milan.

Reports of Societies.

ANNUAL CONGRESS OF THE OPTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

(Continued from p. 692.)

Discussion on Foreign Bodies in the Eye and Orbit, with Special Reference to Prognosis and Treatment.

THIS discussion was opened by Mr. A. L. WHITEHEAD and Mr. HERBERT PARSONS. Mr. Whitehead insisted, in the first place, upon early diagnosis, accurate localization, and early treatment. He pointed out that the great majority of bodies likely to enter the eyeball were opaque to x rays, but that glass (unless of the heavy lead variety), small pieces of aluminium or flint might be missed. He described the giant magnet he was in the habit of using, its great advantage being that it was very mobile and adjustable, and so was easily brought up to the patient's eye. For removal of bodies from the vitreous chamber Mr. Whitehead advocated incision of the sclera as near as possible to the foreign body and extraction by this route, rather than drawing it forward into the anterior chamber and removing it through a corneal incision.

Mr. PARSONS spoke of the need for more accurate knowledge of the anatomical relations of the eye to the orbit. He stated that fragments of copper might cause suppuration even in the absence of all pyogenic organisms, and discussed the chemistry of siderosis bulbi. Fine pigimentary changes at the yellow spot might follow perforation of the eyeball, irrespective of actual injury to this region (a case in which this had occurred was exhibited by the PRESIDENT). Mr. PARSONS stated that he did not think that mere retention of a sterile foreign body, whatever its nature, was of any importance at all, so far as sympathetic ophthalmitis was concerned.

Many members took part in the discussion which followed.

Discussion on the Treatment of Syphilitic Eye Affections by the Newer Methods.

Mr. LAW FORD, having surveyed the gradual development of the organic arsenic compounds, expressed doubt as to their value in the later manifestations of syphilis such as cycloplegia, mydriasis, miosis, and loss of light reflex. He did not think they should be used in cases of primary optic atrophy. In cases of interstitial keratitis he believed the general opinion was that these compounds had no striking effect, and would not prevent the second eye from becoming involved. He considered that the arsenic compounds should always be followed by a course of mercury and potassium iodide.

Mr. S. H. BROWNING spoke from a large experience at Horseferry Road. He advocated many injections of one or other of the arsenic salts supplemented always by mercury. The mercury should be given either by injection or as an intramuscular injection. He advocated the Wassermann test as being an essential indication as to treatment.

Colonel HARRISON spoke from an experience of over 40,000 injections of these salts. He stated that no treatment of syphilis was complete without one or other of them. He believed that kharsivan, salvarsan, and arseno-benzol were all equally efficacious. He was at present giving a concentrated course consisting of eight doses of 0.3 gram salvarsan and six injections of mercury in a month; the course was repeated after the lapse of two weeks if the Wassermann test was positive and if papillitis or ocular symptoms were present. With this line of treatment he had met with 1.6 per cent. of cases of dermatitis, including the very faintest macular eruption. He urged the importance of early diagnosis and early and vigorous treatment.

Mr. ERNEST LANE said that he had given up kharsivan, neo-kharsivan, and arseno-benzol on account of their toxicity. He referred to a case already reported by him in which, after two doses of kharsivan, exfoliative dermatitis and death ensued. He had given galyl almost exclusively during the last fifteen months in the following manner: Four doses of galyl were given at weekly intervals, followed by twelve intramuscular injections of calomel or grey oil, and after three months a Wassermann

test was made. Mr. Lane spoke favourably of luargol, the doses of which were 10, 15, 25, or 30 centigrams over two or three days until 1.2 grams had been administered. He insisted on the importance of early diagnosis and treatment.

Cures following Detachment of the Retina.

Mr. LESLIE PATON read the report of the committee appointed by the society to investigate the cases of cure of retinal detachments, composed of Messrs. Treacher Collins, Creeves, Mayon, Paton, Maitland Ramsay, and Storey. The committee had found it necessary to discard many cases on account of the incompleteness of the records, and no case was considered "cured" unless the retina was known to have remained reattached for at least six months. The 85 cases investigated were distributed amongst the literature as follows: 45 English, 26 German, 10 French, 4 American. In 44 cases the cure followed some operative procedure, and some other line of treatment in 41 cases. The etiological factor in the cases was in 50 myopia, in 11 traumatism, in 6 albuminuria, in 4 albuminuria of pregnancy, and in 1 pregnancy without albuminuria; 13 cases were "idiopathic."

Treatment of Large Traumatic Haemorrhages in the Vitreous.

Captain ORMOND, speaking from his experience at the 2nd London General Hospital, insisted on the desirability of discovering some means of assisting the rapid removal of large haemorrhages in the vitreous so as to prevent their organization with consequent shrinking of the globe. He believed that the beneficial effects of massage, sub-conjunctival injections, ionization, and dionine were due entirely to mechanical causes.

The Peripheral Lesions of Shell Concussion.

Mr. JAMESON EVANS tabulated 50 cases of defective vision ascribed to shell shock; he attributed 6 only to malingering or hysteroneurasthenia. He stated his belief that the ocular symptoms of shell shock were generally due to peripheral lesions rather than to commotio cerebri or psychic trauma.

In the discussion which followed Colonel LISTER took part.

The papers of pure ophthalmological interest were numerous, and were as follows:

Mr. S. Stephenson: A cyst of the pigment epithelium of the iris, with remarks.

Mr. M. Hine: Some observations with the Schiötz tonometer on the normal eye.

Mr. Treacher Collins: Contusion hypotony.

Mr. Affleck Greeves: Observations in a series of trephined eyes examined microscopically.

Mr. Richardson Cross: Severe kerato-iritis cured by tuberculin.

Mr. J. B. Storey: Implantation of fat after enucleation.

Mr. Beatson Hird: Notes on a case of tumour in the retina.

Mr. Gray Clegg: Spontaneous intraocular haemorrhages.

Mr. Maxwell: Capsulotomy after cataract extraction.

Mr. Leslie Paton: Functional spasm of accommodation.

Colonel Lister: Concussion changes in the retina and choroid.

Major Cunningham: Notes on some war wounds of the eye and orbit.

Captain Whiting: A preliminary note on concussion cataracts seen during the war.

Clinical Meeting.

At the clinical meeting at the Central London Ophthalmic Hospital many interesting cases were exhibited, and discussion followed. Captain PINCH, of the Radium Institute, took part in the discussion.

Museum.

During the congress a room was set apart as a museum, which had been got together and arranged by Mr. Mayon.

Localizing x-ray apparatus were shown by Dr. Finzi and Mr. A. D. Reid.

Mr. Holmes Spicer lent a collection of exceptionally beautiful drawings, made by himself, of disease of the fundus oculi.

Specimens exhibiting the results of perforation of the eye by foreign bodies were shown by Colonel Lister and Mr. Parsons (from the Moorfields Museum).

Mr. Mayon exhibited a combination electro-magnet and telephone probe.

Other specimens were shown by Messrs. Pooley, Mackay, Basil Graves, Jessop, etc.

CONTROL OF VENEREAL DISEASE.

At a meeting of the Association of Registered Medical Women on May 9th, Dr. JANE WALKER in the chair, Dr. MARY SCHARLIEB, in opening a discussion on the conclusions and recommendations of the Royal Commission

on Venereal Diseases, said that the Royal Commission was formed as a result of the great interest taken since the beginning of this century in the ravages of syphilis among children, combined with the increased possibility of successful diagnosis and treatment due to the discoveries of Schandinn, Wassermann, and Ehrlich. With regard to notification, it had not been found a success in Scandinavia, while in Italy it was unnecessary, as all who were diseased went willingly for treatment, which was free, and no inquiries were made. At the time when salvarsan had been discovered Rome had been placarded with notices inviting patients to come for treatment. In England the whole subject was kept secret and regarded as shameful, and the result of wrong-doing and notification might lead to loss of employment and of club benefits, etc. Statistics were of little value, as doctors rarely gave syphilis as the cause of death; they gave rather the results, such as aneurysm, epilepsy, etc. Hospital statistics were difficult to obtain, and ordinary general hospitals did not admit cases of recent syphilis, which was regarded as the result of misconduct. A report obtained from a special inspection of Poor Law institutions showed very bad conditions. In some the venereal diseases had been treated in wretched wards, badly lighted and ventilated, the patients unnecessarily confined to bed, and in one the only visitors had been a pauper and his wife acting as caretakers, no doctor visiting the patients. The recommendation that patients, found on admission to a Poor Law institution to be suffering from a venereal disease, should be detained until cured, had been passed after much discussion. This was the most debatable point of the report. Investigation had shown that the examination of female prisoners was not adequate, and the majority considered that medical women should be appointed for this purpose. Education had been specially considered, and it had been suggested that special facilities should be given, both to old-standing practitioners and to medical students, to learn modern methods. The Commission had not been in favour of teaching sexual hygiene to school children. Children should be taught physiology, but not pathology; young adults should be instructed before going out into the world. Teachers in training colleges should receive special instruction to enable them to assist the students; the general public should also be given facilities for instruction, men lecturing to men and women to women. With regard to marriage, divorce, and nullity, if a husband infected his wife, adultery and cruelty could be proved, and divorce instituted. If the husband had been infected before marriage, the Royal Commission considered that he was not in a condition to fulfil his contract, and that nullity should be proclaimed, any children being safeguarded. The Commission also considered that doctors should be protected by law against actions for slander and libel if bona fide they gave essential information to individuals. The Commission thought it impracticable to legislate against quacks, but considered that the law against indecent advertisements should be put in force. In the discussion which followed, Drs. FAIRFIELD, JEVONS, BOLTON, BENTHAM, Lady BARRETT, and the CHAIRMAN took part. Dr. SCHARLIEB, in replying, suggested that opinions of members should be formulated and sent to her or to Dr. Jane Walker, who would bring them before the National Council for Combating Venereal Diseases, on which both were acting.

WE have received the first number of the *Journal of Bacteriology*, a new periodical that is to come out six times a year. It is the official organ of the Society of American Bacteriologists, and is devoted to the advancement and dissemination of knowledge in regard to the bacteria and other micro-organisms. It is planned to make the new journal in particular an organ for the more fundamental and general aspects of bacteriology, but it will also print many papers whose interest is mainly technical, particularly in those fields of bacteriology which have now no satisfactory organ of publication at their disposal. It will include original papers and abstracts of American and Canadian bacteriological literature; perhaps the other literature will be included later. The journal is published at Baltimore, U.S.A., by the Williams and Wilkins Co. It may be obtained in this country through the Cambridge University Press, the annual subscription being 23s. The journal makes a good appearance and no doubt satisfies a want. We wish it all success.

Reviews.

THE INVOLUNTARY NERVOUS SYSTEM.

A SERIES of monographs dealing with branches of physiology which have shown important advances in recent time is to be published under the editorship of Professor STARLING, and the first to appear, *The Involuntary Nervous System*,¹ by the late WALTER HOLBROOK GASKELL, forms an admirably fitting introduction, since it treats of questions which recur in connexion with practically all physiological phenomena. We may well congratulate ourselves that the author had completed the manuscript before his unexpectedly sudden death removed from us a personality who could so ill be spared.

Before Gaskell's researches the sympathetic system had been almost universally regarded as a kind of independent nervous system, presiding over the so-called "organic" or visceral components of the organism. This view was in great part due to the influence of Bichat. Although certain facts had occasionally been pointed out which were not altogether in agreement with this theory, the great advance made by Gaskell was the complete proof that the involuntary nervous system, with which the present monograph is concerned, is entirely motor or excitor in function, and consists of a set of motor neurones sent out from the cerebro-spinal nervous system to structures whose activity is involuntary. Further, that these motor neurones have wandered out from the central nervous system to a greater or less distance, and that the medullated fibres of the white rami are to be regarded as connector fibres, belonging to intermediate neurones, between parts of the central nervous system itself. It is important to note that the afferent nerves of the viscera are not subject to a distinction of this kind.

Gaskell was pre-eminently a man of wide ideas, ideas which have had the most astonishing effect in provoking further work. The great value of Langley's detailed investigations on the manner of distribution of the nerves of the "autonomic" system, as he proposes to call them, receives repeated recognition in the present book. One of Gaskell's master ideas was stated by himself in the preface as follows: "The broader physiological problems cannot be satisfactorily solved without the assistance of morphology, and conversely the larger morphological problems, such as those concerned with evolution, must take into account the facts of physiology." Accordingly, we find that the meaning and significance of facts is continuously brought before us.

We find discussed in order the motor functions of the sympathetic, the bulbo-sacral and the mid-brain outflows of connector nerves, the inhibitory nerves, rhythmic and peristaltic movements, the innervation of glands and the phylogenetic origin of the sympathetic nervous system. A final summary is given. A valuable bibliography and a fairly complete index conclude the work. The reader's grasp of the morphological arrangements described is greatly facilitated by the coloured diagrams. Since, in all probability, the book will become a classic, the suggestion may be made that a portrait of the author would be a suitable frontispiece in subsequent editions.

Before proceeding to further detail, a mild protest may be made against the spelling of the word "neurone." Since the *o* is long, the spelling in English should surely be as given, not "neuron." Similarly, "axon" should be "axone." It is probably due to German influence that the final *e* is omitted. We find Pavlov still spelt in the German fashion. The frequent occurrence in scientific writing of another Germanism, the use of complex adjectives, such as "adrenaline-containing nerve cells," to mean "nerve cells containing adrenaline" or "which contain adrenaline," should also be deprecated. Adrenaline is sometimes spelt without the final *e*, which belongs to it as a definite organic base.

There are several points of importance in connexion with the various systems of connector nerves referred to above, to which our attention is directed. All the vaso-constrictor nerves of the body arise from the thoraco-lumbar or "sympathetic" outflow. It is

stated on p. 35 that there is no evidence whatever of vaso-constrictor fibres in other nerves. It might, perhaps, have been useful in the table on p. 36 to have given references to the papers which established the facts mentioned there, as it is not possible to obtain them from the bibliography. Further, from this same outflow are derived the motor nerves for the muscles of the sweat glands, for all unstriated muscle under the skin, and for all such muscle in structures derived from the segmental duct. The excitor nerves to the sphincters of the intestine arise from the same source. So that we have, as regards the motor or excitatory functions of this system, the supply of a layer of unstriated muscle under the skin, the blood vessels, the tubular structures of the segmental duct, and the sphincters of the intestine. With the constrictors of the blood vessels are to be included the accelerators of the heart. The name "vaso-dermal" is suggested for the muscular group in question. The unity of the sympathetic system is indicated by its extraordinary relationship to adrenaline, a fact to which further reference will be made. Indeed, this hormone is used as a test for sympathetic innervation.

In the bulbo-sacral outflow of motor connectors the cells are not arranged in a series of ganglia, as in the sympathetic; but in plexuses on the surfaces of the organs supplied. These are the plexus of Auerbach in the small intestine, and similar plexuses in outgrowths from this tube in the case of the vagus; on the large intestine and the uro-genital organs in the case of the sacral nerves, where the bundle of connectors is known as the "pelvic" nerve. An interesting discussion is devoted to certain peculiarities in the innervation of the bladder. Just as adrenaline picks out the sympathetic motor activities so does acetyl-choline pick out the motor activities of the bulbo-sacral connectors. The author proposes the name "enteral" for the latter system, to correspond with "sympathetic" for the former. The consideration in the fourth chapter of the outflow of connector nerves to the ciliary ganglion completes this part of the work.

The next chapter is devoted to the inhibitory nerves, and the author meets with greater difficulties here. It is first pointed out that we must admit the existence of nerves in the involuntary system which act upon muscle in such a way as to cause its relaxation directly and not by the putting out of action of a motor cell exciting the muscle, as in the case of voluntary muscle. The effect of adrenaline is evidence in addition to other facts. There exist, then, inhibitory nerves and cells in addition to motor ones. While the neurones of the two kinds are found peripherally in close contiguity, it does not always happen that the connector nerves pass out in the same outflow. In fact, as a rule, inhibitory cells of the enteral system have travelled out from the central nervous system along with excitor cells of the sympathetic and vice versa. An interesting fact is referred to in relation to this circumstance. The axones of many large nerve cells in invertebrates divide while still in the central nervous system. One fibre passes out as a large motor fibre to a group of muscles, while the other passes to the opposing muscles. It seems clear that one of the two must be inhibitory in function. The possibility of such an arrangement in the case of the cardiac fibres of the vagus is shown to be capable of explaining the apparent anomaly of these fibres being purely inhibitory in the majority of vertebrates, while having an excitor function on the muscle fibres responsible for the tonic changes in the tortoise auricle. Otherwise the double excitor and inhibitor innervation of the heart is clear. When we come to the inhibitory nerves of the blood vessels, the vaso-dilator nerves, we are met by the difficulty that in the activity of an organ metabolic products of an acid nature appear, which act directly on the muscle of the arterioles in such a way as to cause its relaxation. Nevertheless, there are many cases in which such an explanation of vascular dilatation is, to say the least, somewhat forced, and there is surely no difficulty in holding that the smooth muscle of the blood vessels resembles that in other situations in possessing a double innervation, and not one of excitors only. The explanation of the curious vaso-dilatation obtained from stimulation of peripheral ends of sensory nerves is perhaps one of the cases referred to in the preface as being not very satisfactory to Gaskell himself. It is rather remarkable that, while applying Langley's axone-reflexes to some

¹ *The Involuntary Nervous System*. By W. H. Gaskell, M.A., M.D., F.R.S. Monographs on Physiology, edited by E. H. Starling, M.D., D.Sc., F.R.S., F.R.C.P. London and New York: Longmans, Green and Co. 1916. (Med. 8vo, pp. 186; illustrated. 6s. net.)

other cases, he does not consider the possibility that has been suggested of its application to this case.

Chapter VIII is devoted to the consideration of the rhythmic movements of the heart and to the movements of the intestine. The former is especially valuable, as coming from the originator of the myogenic theory of the heart beat. Auerbach's plexus is regarded by Gaskell as demonstrably belonging to the vagus alone as regards its nerve cells, and this suggests an explanation of the "myenteric reflex," as it is called by Cannon, which does not involve the assumption of a true reflex. This explanation is on the lines of the fact referred to above, where the nerve fibres from one cell may simultaneously excite one muscle cell or motor neurone and inhibit another. A further discussion of this interesting question will be found on page 147 of the monograph. The phenomenon in the intestine must be a function of the vagus alone, since the sympathetic supplies no nerve cells to it. It seems that the original name of "law of the intestine," given by Bayliss and Starling may turn out to be more correct than the later one of Cannon.

As to the innervation of glands with ducts, it is pointed out that, omitting the kidney, which belongs to another category, there are two systems of nerve cells—namely, (1) those supplying epidermal structures, sweat glands, etc., which belong to the sympathetic system, and (2) those of the enteral system, belonging to the bulbar outflow. At the two extremities of the body a mixture takes place, so that the salivary glands, for example, receive a secretory innervation from both systems.

Chapter X gives an account of the position of the cells in the central nervous system from which the connector fibres of the involuntary nervous system take origin. The sympathetic and sacral outflows clearly arise from the lateral horn. Those in the cerebral outflows have a more complex origin, but there is much evidence for the view which assigns their origin to a column of the same nature as the lateral horn of the spinal cord.

As is natural, we find repeated references to the author's well-known theory of the origin of vertebrates, and Chapter XI is specially devoted to the phylogenetic origin of the sympathetic system. Whatever may be the opinion held as to the main theory, there can be no doubt of the extraordinary manner in which it throws light on difficult problems. It should receive welcome from the physiologist especially, on account of the preponderance given to the evolution of the central nervous system, with its control of the whole organism. The present reviewer regards the evidence as strong enough to bring almost complete conviction. Space does not permit of more than reference here to the interesting relations of the chromaffine cells and their adrenaline content to the sympathetic system.

Enough has been said to show how necessary a knowledge of the contents of this important monograph is to all those concerned in any way with the involuntary nervous system, be they morphologists, physiologists, or engaged in the practice of medicine.

W. M. B.

CLASS GYMNASTICS FOR WOUNDED MEN.

We noticed some time ago the appearance of a book by Dr. M. Carle (BRITISH MEDICAL JOURNAL, December 11th, 1915, p. 862) describing the schools for the industrial training of disabled soldiers established in France, and a further reference to the matter will be found in the JOURNAL of May 6th, p. 668. A small volume recently published by Dr. CH. GUILBERT and M. G. MAUCURIER,² supplements Dr. Carle's book by describing the advantages of gymnastic classes for dealing with the re-education of wounded soldiers at certain stages. Dr. Guilbert is at the head of the department for treatment by movement and gymnastics at the military hospital in the Grand Palais, Paris, and M. Maucurier is professor of physical education in the public schools of Paris. The authors, while fully recognizing the necessity for individual treatment in the early stages of most cases, have found that gymnastic exercises in class may be extremely useful later on; their book describes at length the various exercises which they have found most generally applicable. They

² *Guide de rééducation physique en groupe. Méthode de gymnastique rééducative pour les blessés militaires.* Par le Dr. Ch. Guilbert et G. Maucurier. Paris: J. B. Baillière et Fils. 1916. (Cr. 8vo, pp. 128; 59 figures. Fr. 2.50.)

attach great importance to the mental effect when men suffering from similar disabilities do exercises together. A spirit of emulation is aroused, and the appeal to his imagination encourages a man to make efforts which, if working by himself, he would find wearisome. Gymnastics in class are not applicable until the patient has attained a certain power of movement, but once that stage has been reached progress may be rapid. It has been found that no lesson should last more than half an hour, that no class should consist of more than twenty men, and that the teacher should have the help of a monitor who will show individuals who fail to accomplish a movement where their fault lies. The difficulty of obtaining good monitors is recognized; some have been found among wounded men who have themselves made good progress. They are given a short course of instruction for three or four weeks and then begin to work under the teacher. The greater part of the book consists of detailed instructions for various types of exercises with and without appliances. The directions are illustrated by excellent sketches, and the book altogether is of a thoroughly practical and helpful character.

PERSIA.

Dr. A. R. NELIGAN,³ physician to H.M. Legation at Teheran, has written an excellent account of the medical knowledge that should be at the disposal of all residents and travellers in Persia. There are but few of either class, so far as our own countrymen are concerned, now in Persia. In the past, however, Persia has owed much to the activities of its more civilized European residents; and when the shadow cast on all Eastern countries by the present war of German aggression has passed by, no doubt the British officials, travellers, and traders will return to Persia once more. Dr. Neligan's book combines the functions of a medical manual for laymen with those of a general guide to the country and its chief routes for travellers; the earlier pages give a brief account of how to live and dress and eat in Persia. Antityphoid inoculation is mentioned as an indispensable preliminary to travelling in Persia; water must never be drunk without preliminary boiling; mosquitos occur in most parts of the country, and mosquito nets should always be at hand; derangements of the digestion are peculiarly common, and often due to certain articles of Persian diet that prove too much for the unarméd digestive powers of Europeans. More than half the volume is taken up with details of the main routes in the country, with a few notes about the chief places and objects of interest to be seen. The notes as to the use of motor cars in Persia lead one to suspect that the roads must be generally execrable. The book is full of interest, and should have a future.

NOTES ON BOOKS.

VOLUME III of the second edition of the *Encyclopædia Medica*,⁴ issued under the general editorship of Dr. J. W. BALLANTYNE, contains articles from *Chloroform* to *Dyspnoea*. The authors are for the most part Scotsmen of medical or surgical distinction. Among the most important and interesting articles in the volume are those on chlorosis, chorea, colour vision, convulsions, deformities, diabetes, diet, and dysentery. The general scope and excellence of this *Encyclopædia* are well known, and need not be emphasized further in the present brief note. It may be added that the article on diabetes insipidus would, perhaps, gain by a reference to Finkelnburg's work on the division of the cases—namely, those with a primary polydipsia and those with a primary polyuria; further, a reference might with advantage be given to Weil's account of the 229 descendants of one J. P. Schwartz, in five generations, out of whom 34 exhibited hereditary and apparently harmless diabetes insipidus.

The Seven Ages of Woman,⁵ by Dr. MARY SCHARLIEB, is the best book of its kind we have seen. It is written in an

³ *Hints for Residents and Travellers in Persia.* By A. R. Neligan, M.D., London, M.R.C.S., Eng., D.T.M., and H. Cantab. London: J. Bale, Sons, and Danielsson, Ltd. 1914. (Cr. 8vo, pp. 201; 1 map. 5s. net.)

⁴ *Encyclopædia Medica.* Under the general editorship of J. W. Ballantyne, M.D., C.M., F.R.C.P.E. Volume III, *Chloroform* to *Dyspnoea*. Second edition. Edinburgh and London: W. Green and Sons, Ltd. 1916. (Roy. 8vo, pp. 680; illustrated. 20s. net.)

⁵ *The Seven Ages of Woman: A Consideration of the Successive Phases of Woman's Life.* By M. Scharlieb, M.D., London, New York, Toronto and Melbourne: Cassell and Co., Ltd. 1915. (Post 8vo, pp. 239. 6s. net.)

easy, pleasant way, and in it advice and guidance are given, as its title suggests, to girls and women. The book is divided into seven parts, and begins with most helpful advice on the upbringing of girls. The parts devoted to the young wife, the young mother, and nursing mother, are likely to be particularly helpful to those to whom they are addressed, for in them the advice is sound and practical, neither alarming the ignorant nor making the more experienced mother too bold. The chapter on the "Mother in the noisy years" deals with the problem of childhood, while that on the "Woman in middle and old age" shows how health may be maintained when the vigour of life is passing. Mrs. Scharlieb seems to us to have struck the right note throughout the book, and the appendix with its list of simple formulae will be useful to those who turn to the book for help and guidance. We would suggest that it would have been better to have adopted a paper cover to the book less in the style of the cheap novel of the bookstall, and we trust this may be done in future editions.

CEREBRO-SPINAL FEVER.

THE Local Government Board in England has issued a Blue Book of nearly 200 pages on cerebro-spinal fever, with special reference to the occurrence of the disease since the outbreak of the war.¹ The volume contains five reports by different workers, and an introductory memorandum by the medical officer.

Epidemiology.

Dr. Bruce Low contributes an essay occupying some seventy pages on the prevalence of cerebro-spinal fever throughout the world in recent times. It gives a very clear comprehensive survey of the history of the disease for the last thirty years, within which period knowledge of its nature has made great progress. It describes the occurrence of the disease in the British Isles at considerable length, and then passes on to the observations of outbreaks in France, the Low Countries, Scandinavia, Germany, Austria, Russia, Roumania, the Mediterranean, Switzerland, Portugal, and Spain, as well as in Africa, New Zealand, India, China, and in the American continents. The essay will possess permanent value, but it is particularly useful at this time in that it puts recent outbreaks in proper perspective.

Dr. R. J. Reece has written a report on cerebro-spinal fever among the civil population in England and Wales with special reference to outbreaks in certain districts during the first six months of 1915. The districts especially dealt with at length are Wiltshire, where a certain number of cases occurred in the second part of 1914 and in the early part of the following year, Reading, Bristol, Portsmouth, and Liverpool. It does not include a full account of the incidence of the disease among troops, but this report, and that of Dr. Bruce Low, give examples of the excellent work done by the medical executive of the Local Government Board. They show that though small outbreaks occurred in the British Isles at earlier dates, the first of any magnitude to be recognized took place in Glasgow and Belfast in 1907. As it is well known that the bringing together of a large number of recruits in camps and billets is very apt to be followed by a prevalence of the disease, the danger was foreseen, but as a matter of fact it appears that one of the Canadian contingents had cases at Valcartier camp before leaving Canada; cases continued to occur after they had reached this country and were encamped on Salisbury Plain, and the disease was definitely established among them by the end of 1914. It should be noted, however, that a few cases had occurred among the civil population early in the autumn, and a few more in December. During the first half of 1915, 9 cases occurred in Wiltshire, the largest number being observed in February. In 1915, 40 cases occurred in the city of Salisbury, which had become a busy military centre, 11 in other urban districts in the county, and 39 in rural districts. The Corporation of Salisbury established under the direction of Dr. Penfold, of the Lister Institute, a bacteriological laboratory for the diagnosis of cases and for the detection of carriers. The inhabitants were advised to submit to inoculation with a vaccine prepared from killed cultures of a local strain of the

meningococcus, and the M.O.H., Dr. Fison, estimates that at least 3,500 persons received preventive inoculation—that is to say, about 31 per cent. of the census population. Special attempts were, however, made to secure the inoculation of all contacts, and the results were such as to encourage resort to this measure in any future outbreak. Dr. Fison reported that the reaction from the inoculation was not severe, that no inoculated person contracted the disease; in two instances all the junior members of a family had been inoculated except the one attacked, and in another the father was attacked, but his inoculated children escaped. The outbreak in Reading included some twenty cases among the troops billeted in the town. The first civil case occurred on January 14th, and no connexion with the military could be traced. The first military case occurred on February 7th. The danger was dealt with energetically by the corporation and its officers with the assistance of the military authorities by way of isolation, early bacteriological diagnosis, and treatment of contacts. Cases, however, continued among the civil and military population during the whole of the period under review—namely, the first six months of 1915. In Bristol 90 cases were notified in the first six months of 1915. There had been 32 cases among the civil population in 1914, the majority children, though 6 were over 20 years of age. In Portsmouth the first cases occurred among the naval and military population, but subsequently over 50 were notified among the civilians. A small outbreak in Winchester seems also to have originated from the military. In a concluding note Dr. Reece points out that of the 2,045 cases known to have occurred in England and Wales during the first six months of 1915 the majority—1,656, or 81 per cent.—were observed south of a line drawn from the Wash to the Bristol Channel. For military purposes the greater number of troops were stationed in the east and south-east part of England, and the facts, he considers, confirm the belief that a manifestation of the disease was in some way associated with the presence of troops in the areas specially affected.

Bacteriology.

The bacteriological questions which arise are discussed in three reports by Dr. Eastwood, Dr. F. Griffith, and Dr. W. M. Scott; these are concerned largely with the prevalence of meningococcus-like organisms in the naso-pharynx. Dr. Eastwood, however, gives a long and interesting historical survey of the growth of knowledge, but he begins with 1906, so that he attributes to Lingelsheim the first observations on the value of fermentation tests for these organisms, thus ignoring the paper by Dunn and Gordon published in this JOURNAL in August, 1905, in which Lingelsheim's results were to a large extent anticipated.

In the second part of his report Dr. Eastwood gives an account of the investigations made in the Board's laboratory, describing the method adopted by himself and Dr. Fred. Griffith for the investigation of meningococci from cerebro-spinal fluid, and relates investigations made by them and by Dr. W. M. Scott on naso-pharyngeal swabs from non-contacts. The contribution from Dr. Griffith is on the identification of the meningococcus in the naso-pharynx, with special reference to serological reactions. His general conclusion is that all strains of Gram-negative cocci obtained from the naso-pharynx which are identical microscopically, culturally, and in fermentation tests with meningococci must, in default of a specific test for virulence and until the serological relations have provided definite evidence to the contrary, be considered to be meningococci.

Dr. W. M. Scott's conclusion from his study of meningococci occurring in spinal fluid and of similar organisms in the naso-pharynx does not materially differ. He states that micro-organisms indistinguishable from meningococci by microscopical, cultural, and fermentation tests were found in the naso-pharynx in 22 per cent. of 138 non-contacts from an urban population (Lambeth out-patients). In 63 per cent. of these organisms the serological tests, he considers, confirmed their identity with meningococci, or their close relationship to them. The agglutinating properties of the organisms were not, in general, so strongly marked with the serums used as those of known pathogenic strains, but they showed definite absorption

¹ Reports of the Local Government Board on Public Health and Medical Subjects in series. No. 110: Reports on Cerebro-spinal Fever. Price 2s.

of the specific agglutinin. They appeared to differ from the majority of the spinal strains not in the quality, but in the quantitative intensity of their specific affinities. Some spinal strains, however, resemble them in this. The patients, as has been said, were believed not to have been in actual contact with cases of cerebro-spinal fever, but a considerable number of cases of the disease were occurring in London and elsewhere, so that this point does not seem to be completely established.

Dr. Newsholme, in his introductory memorandum, expresses the opinion that the special importance of the results obtained by the investigations of the Local Government Board lies in the fact that they were concerned with persons who had not been in close association with cases of cerebro-spinal fever. He acknowledges that the investigations, which are being continued, have not, so far, settled the question of the measure of importance which should be attached to the finding of meningococcus-like organisms in the naso-pharynx.

From the summaries of the investigations of Drs. Eastwood and Griffith it appears that altogether 480 swabs from the naso-pharynx of non-contacts were examined, and that of these 49 yielded cultures which resembled meningococci in their morphological and cultural characters, and in their response to fermentation tests. It appears that of these 49 cocci 28 were investigated serologically. For this purpose Dr. Griffith used, we gather, seven monovalent serums prepared by him from strains isolated from the cerebro-spinal fluid of cases of the disease. While 15 of the naso-pharyngeal cocci showed good agglutination, 6 gave a less marked result, and 7 gave either a slight or a negative reaction. It is added that five of these naso-pharyngeal strains absorbed from the respective agglutinating serums the specific agglutinin for the homologous strain of meningococcus, but nothing is said as to the behaviour of the others in this respect. In an attempt to summarize the matter, we find that out of 49 meningococcus-like organisms collected from the naso-pharynx of 480 non-contacts 28 were submitted to serological examination, and that of these 5 gave evidence by absorption tests that they were true meningococci. As to all the others considerable doubt must be felt, and from Dr. Newsholme's observation on the point it would appear that the serological evidence is against their being meningococci. Dr. Scott examined the naso-pharyngeal secretion from 138 out-patients at the Lambeth Infirmary and 56 children at a rural school in Kent; 30 of the Lambeth cases and one of the school children yielded cocci that resembled the meningococcus in their cultural and fermentative characters; 29 of them were submitted to serological tests, and 7 showed complete agglutination at 1 in 200, or in higher dilution; 12 did not appear to have agglutinated in a higher proportion than 1 in 100, and the remainder, including that from the school child, showed only slight agglutination with the serums employed. On the whole, therefore, it does not seem that the evidence Drs. Eastwood, Griffith, and Scott have advanced establishes the proposition that more than a proportion of the meningococcus-like organisms found in the throats of these non-contacts were true meningococci.

Difficulties in the Identification of the Meningococcus.

There can be no doubt that the identification of the organism in the naso-pharynx is not a simple matter. One difficulty arises from the fact that the investigation during the recent epidemic of meningococci from the cerebro-spinal fluid itself has shown that while the organisms may be alike in their morphological, staining, cultural, and fermentative characters, they differ among themselves in their serological characters. A number of types have been distinguished, but it would appear from the work of Colonel M. H. Gordon and Mr. E. G. Murray at the Central Cerebro-spinal Fever Laboratory at the R.A.M. College, Millbank,² that, so far as concerns cases of cerebro-spinal fever occurring among the military in this country, only four different types need, for practical purposes, be considered; of these four types only two occurred with any considerable frequency. Captain Ellis and Dr. Arkwright have also found evidence of at least two distinct types. Another difficulty in the way of the in-

vestigators is that the naso-pharynx and other parts of the upper respiratory passages habitually contain various sorts of Gram-negative cocci. The more common of these differ so much in their morphological, cultural, or fermentative characters from the meningococcus that they can be easily distinguished. There are other Gram-negative cocci, however, which it would seem can only be distinguished from the meningococcus by their serological characters. This test, therefore, is of great importance, and appears to be the most trustworthy means of identifying the meningococcus of any one of the various types distinguished. Elser and Huntoon, of whose researches for the Health Board of New York Dr. Eastwood gives an account, as well as other workers both in Germany and in this country, have fully established the point that Gram-negative cocci may be found in the naso-pharynx which resemble the meningococcus in morphological, cultural, and fermentative characters, but are serologically distinct, and Elser and Huntoon apply to them the term "pseudo-meningococci," distinguishing six strains. These pseudo-meningococci have been found in certain cases of catarrh and colds in large numbers in the secretion of the respiratory passages, and may possibly be the cause of catarrh, but so far as present evidence goes they are not true meningococci.

Immunology.

From the report of the Medical Research Committee already mentioned, it appears that Colonel Gordon and his colleagues at the R.A.M. College have now worked out in detail the immunological characters of the strains of meningococcus concerned in the past epidemic, and the laboratory now supplies monovalent rabbit serums which will agglutinate all the epidemic strains of meningococci commonly found up to a dilution of 1 in 400. These homologous serums will, it is expected, facilitate the recognition of the epidemic types of the meningococcus, and will, moreover, afford the serum treatment a better chance than it has hitherto had to prove its value. Not only will it be possible to produce a properly balanced polyvalent serum for general use, but by identification of the type of coccus in any given case the way will be opened for the use of a monovalent homologous serum presumably of greater potency. Such serums are already in preparation. Provided with a series of specific agglutinating serums of the various types of meningococcus occurring in the cerebro-spinal fluid, the bacteriologist will be able to distinguish the true meningococcus when it occurs in the naso-pharynx, and will be justified in refusing to admit any suspect coccus from the naso-pharynx to be a true meningococcus unless its serological behaviour corresponds with one or other of the types found in the cerebro-spinal fluid of developed cerebro-spinal fever.

THE DR. JAMES B. BIRD MEMORIAL FUND.

In the notice of the life of Dr. J. B. Bird, of Carlisle, published in the JOURNAL of May 13th, p. 706, it was said that he had died at so early an age that he had been unable to make due provision for his family, and that a committee had been formed for the purpose of raising a memorial fund for the education of his children. We are informed that the fund already amounts to £1,190; further subscriptions should be sent to the honorary treasurer, Mr. James Nelson, Bank of Liverpool, Limited, Carlisle. The fund will be administered by trustees. The proposal has been warmly taken up by the members of the Border Counties Branch, and the following is a list of subscriptions already received from medical friends:

	£ s. d.		£ s. d.

British Medical Journal.

SATURDAY, MAY 20TH, 1916.

CERVANTES AND MEDICINE.

CERVANTES, the tercentenary of whose death, like that of Shakespeare, falls in the present year, took as keen and intelligent an interest in medicine as his great contemporary. Hernández Morejón, in his *Historia Bibliografica de la Medicina Española*, devotes a chapter to the "beauties of practical medicine discovered in the immortal work of Cervantes." Olmedilla y Puig, Cristóbal Pérez Pastor, Menéndez Pelayo, Pardo Figueroa, and many other writers have treated of his medical knowledge. His father, Rodrigo de Cervantes, was a surgeon apothecary, and he had himself a considerable experience as a patient. At Lepanto, when his ship, the *Marquesa*, came into action, he was below, ill with fever, but he insisted on playing his part in the fighting, and received three gunshot wounds, two in the chest and another which permanently maimed his right hand. The hardships and privations which he endured as a captive in the hands of the Moors, and the lifelong poverty and frequent imprisonment which he suffered after his escape undermined his health. Professor José Gomez Ocaña, of the University of Madrid, in his essay on the clinical history of Cervantes published in 1899, expressed the opinion that he was the subject of arterio-sclerosis and heart disease; it is known that he died of dropsy. The word "corazon" (heart) occurs 141 times in *Don Quixote*; of course it is not always used in the literal sense, but this frequency may perhaps not be without significance. Cervantes mentions about a hundred plants, describing their medicinal and alimentary uses, and he was acquainted with the great compilation of Dioscorides on materia medica, at least in the Spanish translation of Andrés Laguna of Segovia, physician to Charles I (afterwards the Emperor Charles V) and Philip II. He had also read Pliny's *Natural History*, then held in Spain, as it was in England at that day, as of high authority on all things medical. He speaks of poisons which breed madness in men's brains, and discharges shafts of satire at druggists and doctors, but it is only pretenders and impostors at whom they are aimed.

In more than one passage Cervantes scoffs at secret and superstitious remedies. When Don Quixote is losing blood after a fight, he regrets that he had not by him the Balsam of Fierabras, a medicine of such potency that if his body were cloven in twain, one part could be accurately adjusted to the other "before the blood congeal," when two draughts would make him "sounder than an apple." This balsam was believed to be a part of that used by Joseph of Arimathea to embalm the body of Christ. Elsewhere Sancho prepares for his bruised master a compound of simples, over which he says a number of Paters, Aves, Salves, and Credos, with many signs of the cross.

Cervantes makes some unmistakable allusions to venereal disease. In *El Casamiento Engañoso* there is a description of an unfortunate officer leaving hospital where he had sweated away fourteen loads of buboes given him by a woman. In the same work mention is made of a disease called *lupicia* (alopecia) or *pelareta* (from *pelar*, to pluck out hair), treated by

sweating, which makes all the hair, including the eyebrows, eyelashes, and beard, fall out. The scene of the *Coloquio de los Perros* in the *Novelas Ejemplares* is laid in the hospital of the Resurrection at Valladolid. In many places Cervantes dwells on the hygienic value of plain diet and moderation in eating. Delightful fun is made of the dietetic crank, Dr. Pedro Recio de Agüero, who stands beside Sancho when he is at table and condemns the various dishes set before him—one as being too moist, another too heating, and so forth, till the starving governor of Barataria threatens to knock him on the head with the chair on which he is sitting, saying that if he is charged with murder he will plead in excuse that he has rendered a service to God by killing a bad doctor.

It was disease of the mind which most interested Cervantes, and Pi y Molist has written a book on him as a medical psychologist. If Cervantes does not bring so many mad folk before us as Shakespeare, he gives in *Don Quixote* the most finished picture in all literature of a certain type of insanity. Much reading of romances of chivalry had made the Knight of the Sorrowful Countenance mad. On all other subjects he was of good understanding and could discourse rationally. Cervantes speaks of hallucinations of smell which make the Don describe as an aromatic fragrance the odour diffused by his Dulcinea and attributed by the prosaic Sancho to perspiration from much exercise. He also refers to the loss of memory which makes the Knight exaggerate his adventures as caused by continual and extraordinary labours. The methods by which those about him seek to divert his mind from the exalted ideas which had led him to go about in search of adventures show that his creator had a clear notion of the value of moral treatment. The last illness of Quixote, in which he passes from madness to profound melancholy and recovers his reason with the onset of fever, may be compared with the death of Lear. Sancho Panza is an example of what Charles Lamb calls the "twilight state of insanity, the madness at second hand, the contagion caught from a stronger mind infected." In *El Licenciado Vidriera* Cervantes gives a picture of madness brought on in a student of Salamanca by a love philtre, such as is said to have caused the death of Lucretius. The young man imagined that he was made of glass from head to foot; when any one came near he would call upon him with terrible cries to keep away, lest he should be broken.

In the "Colloquy of the Dogs" we get a glimpse of the overcrowding of the medical profession in Cervantes's day. A student of Alcalá is quoted as saying that of the 5,000 students in that university 2,000 belonged to the medical faculty. The comment on this remark is that either all these doctors would require to have sufficient patients to cure—"which would be a terrible disaster"—or they must die of hunger. This makes one think of Abernethy's exclamation, on entering the crowded theatre of St. Bartholomew's on the opening day of a winter session: "God help you, gentlemen! What is to become of you all?"

The number of references in the works of Cervantes to medical subjects might be multiplied indefinitely. Like Shakespeare, he knew something of everything. He was not only a man of the most powerful creative faculty, but a close observer of facts and a deep thinker. It is not surprising, therefore, that he should have been made the subject of study by doctors. It would, of course, be absurd to regard *Don Quixote* as a medical treatise. But it is one of the profoundest studies of human nature ever made, and as such it is full of

instruction for the doctor, for there is a deep truth in the saying of a Spanish physician, Letamendi, that the man who only knows medicine does not know even that. The story of Richard Blackmore asking Sydenham what books of medicine he should read and being told, "Read *Don Quixote*; it is a very good book; I read it still," is well known. On this Johnson in his ponderous way observes that "the perverseness of mankind makes it often mischievous in men of eminence to give way to merriment. The idle and illiterate will long shelter themselves under this foolish apophthegm." But is it foolish? According to Frank Payne the obvious meaning is "Read what you like; reading books will never make a doctor." This interpretation would be quite in keeping with the character of Sydenham, who despised book learning and had no great respect even for science. But we are inclined to believe that he was at any rate partly in earnest, for the practitioner's equipment is incomplete without a knowledge of human nature, and this can only be got by a study of the great masters of the human heart who hold the keys that open the fountains of tears and laughter. Chief among them are Shakespeare and his immortal Spanish contemporary.

BACTERIOLOGY AND BREWING.

BEER has but few outspoken friends nowadays. Its patrons may still be many, whatever the degree of success attained by the discouragements effected by the Central Liquor Control Board, and however excellent the work of that Board is. But there is nothing heroic about the subjects of beer and brewing, nothing to stir the imagination. Hence people are apt to forget the great influence exercised by the brewing industry upon the development of the science of bacteriology in the Sixties, Seventies, and Eighties of last century. This influence has been traced out in detail by Mr. Horace T. Brown, F.R.S., in an interesting address read before the Institute of Brewing last week. Mr. Brown has been closely connected with the brewing industry for half a century, and so is enabled to speak with first-hand knowledge of the trials and triumphs of those who endeavoured to apply scientific method to brewing practice in those far-off days.

It is just sixty years ago since Pasteur began his epoch-making studies in fermentation. He was living in Lille, and distillation was a very important industry in the town and its neighbourhood. He was consulted by a Lille distiller named Bigo, in 1856, as to certain difficulties met with in the manufacture of alcohol from beetroot. At that time the prevailing scientific notions about fermentation were those formulated by the celebrated chemists Liebig and Berzelius, and were wholly erroneous. The latter attributed fermentation to an obscure catalytic force, and regarded the yeast cells as a mere precipitation of a vegetable principle during the process. Liebig, on the other hand, defined ferments as extremely alterable organic substances able, under the influence of oxygenation, to communicate molecular motion to sugar and induce its decomposition into alcohol and carbonic acid gas.

Such ideas as these, however interesting from the historical point of view, were naturally sterile when confronted with the practical difficulties of the brewer. Pasteur swept them all aside, and after elaborate study and experimentation was able to state in 1860 that alcoholic fermentation was correlative with the life and organization of the yeast cell; a few years

later he was able to go further and show that each of many fermentative processes had its own specific organism by which it could be recognized. He linked up his work on alcoholic fermentation with that on the souring of milk and the lactic fermentation of sugar; and in 1863 took up the study of the fermentations involved in the production of wine, the greatest of French industries, publishing a book on the subject in 1866. Continuing his work on industrial fermentations, he wrote a book on the subject of beer in 1876. Thus the first twenty years of his active scientific life were largely occupied with the investigation of problems raised by the great fermentation industries, and he returned to them again and again in later years, as his biographer Vallery-Radot shows. The practical commercial value of his discoveries was incalculable; the scientific importance of the work was no less, and may not unfairly be regarded as one of the contributions made by beer to bacteriology. But beer has contributed more than that. Mr. Brown gives a most instructive analysis of the influence exercised by Pasteur's work on the development of Lister's antiseptic surgery in the Sixties. The researches from which Lister drew his inspiration were those suggested to Pasteur by his observations in Bigo's distillery at Lille.

Mr. Brown has many interesting facts to record in illustration of the slow progress made with the introduction of scientific methods into the conservative art of brewing. In the late Sixties there was no laboratory at all in the great Burton brewery he entered. It was not until 1869 or 1870 that he turned his attention to the systematic use of the microscope in his brewing work. The polarimeter, now indispensable to the brewing chemist as a means of estimating sugars, was not applied to this obvious service until 1870, when O'Sullivan took it in hand with brilliant results. The scientific members of the staffs of the various Burton breweries waited till 1876 before forming an informal scientific club for the discussion of scientific discoveries in chemistry and biology that had a bearing on the fermentation industry. It was not till 1879 that Hansen's work on the identification and cultivation of pure yeasts at the Carlsberg laboratory in Copenhagen began. It was not till the close of last century that the Guinness Research Laboratory was started in Dublin; for it Mr. Brown laid out a detailed scheme of work in 1901. In the closing paragraphs of his address Mr. Brown points out many other particulars, besides those already mentioned, in which science owes a debt to the fermentation industries; at the same time he shows how the benefits conferred have been mutual.

Other sciences besides bacteriology have gained by investigations set on foot by workers primarily interested in brewing. Chemistry has been enriched by a vast amount of work on enzymes, sugars, starch, to mention but a few out of many pioneer labours; vegetable physiology has learnt much from brewers, more particularly with regard to the synthesis of starch from carbon dioxide by chlorophyll-containing leaves; Pasteur's work on crystalline isomerism and molecular asymmetry was suggested to him by his bacteriological studies in the first instance, and has developed into the corner-stone of organic chemistry. Therapeutics has received illumination, as, for example, from the work of Raulin, a pupil of Pasteur, who found that minimal quantities of zinc salts might exercise a wholly disproportionate influence on the freedom with which moulds grow in artificial media; even 1 part of zinc in 100,000 of the nutritive solution in which the fungus was grown seemed

sufficient for its needs. This work has recently been confirmed and extended by Javillier,¹ who found that the addition of 1 part of zinc to over 50 million parts of culture medium was enough to increase the growth of the mould by 30 per cent. Figures such as these impress the imagination with the importance of the infinitely little, and at first sight may even seem to offer a general confirmation of the views of homoeopathy. But, applying the same figures to the case of a human being and the drug arsenic, it will be seen that the "infinitely little" suggested by the dilution of one in fifty million, in the case of the mould, is really a commonplace of daily medical practice. In Javillier's experiment quoted above the amount of zinc involved was 0.005 mg. in 250 c.cm. of culture medium, the amount of mould grown was 2.5 grams, dry weight, and the proportion between the two last quantities was 1 to 500,000. In the case of a human being weighing 11 st. the dry weight may be taken as 66 lb., or 462,000 grains; while the pharmacopoeial dose of arsenious acid is given as from one-sixtieth to one-fifteenth of a grain. Clearly, then, in order that the human being may receive as much arsenic, relatively, as the mould received of zinc in Javillier's experiment, a great many doses of the arsenic must be exhibited; in other words, the human being is more sensitive to the action of arsenic than the mould is to salts of zinc.

These considerations have led us rather far, perhaps, from the thesis of Mr. Brown's vindication of the scientific value of the fermentation industries and the history of their development from the laboratory point of view. But nobody can read his address, inspired as it is by the conviction bred of a deep knowledge of the subject, without feeling that in the growth of bacteriological science the art of brewing has played a most important part. And these are not the days when such a debt to the brewing industry should be forgotten.

THE LISTER INSTITUTE.

THE annual meeting of the members of the Lister Institute was held at the Institute, Chelsea Gardens, on May 17th. Surgeon-General Sir David Bruce, C.B., F.R.S., the chairman of the Governing Body, who presided, in presenting the annual report referred to the loss the Institute had sustained by the death of Sir Henry Roscoe, who took an active part in its foundation, and who had been subsequently, first as treasurer and afterwards as chairman of the Governing Body, intimately concerned with its welfare throughout the whole of its history. The Institute had also lost by death Mr. Pattison, who had been treasurer since 1899. His place had been taken by Lieutenant-Colonel G. W. Addison, R.E. In pursuance of the policy instituted by the Governing Body in 1914, the Institute had continued during 1915 to devote its energies almost entirely to war work. It had been deprived of the services of many of its permanent staff, including the director, Professor C. J. Martin, and many voluntary workers in the laboratories, who had been claimed by the army. The amount of original investigation and the number of papers published were on this account much smaller than usual; on the other hand, a great deal of important work in relation to the prophylaxis of disease had been carried on. The bacteriological department had prepared large quantities of typhoid, paratyphoid, and cholera vaccines for military purposes, and researches on the disinfecting action of hypochlorites were being conducted by Dr. Schütze, and on prophylactic

dysentery vaccines by Dr. J. D. Thomson. The Chairman paid special tribute to the manner in which Dr. MacConkey had overcome many difficulties at Elstree, and with the assistance of Dr. Zilva and Miss Homer had prepared large quantities of antitoxins for the use of the army and navy. Cultivations of strains of the meningococcus isolated from cases of cerebral meningitis had been used for the immunization of horses, and the serum so obtained had been employed with success both in France and at home. Much use was being made of the Institute's antidysentery serum, which also had given good results. The Governing Body expressed its indebtedness to the Hygienic Laboratory of the Public Health Department of the United States of America and to its director, Dr. J. F. Anderson, for the generous manner in which, after the outbreak of war, they placed at the disposal of the Institute supplies of standard diphtheria antitoxin and standard tetanus toxin. In the department of experimental pathology, of which Dr. C. J. Martin is director, the assistants, Miss Harriette Chick, D.Sc., and Miss Mabel Rhodes, had been largely occupied in the manufacture of agglutinating serums for the use of the army and navy medical services, and in this department various foodstuffs had been examined for the presence of vitamins, in view of the occurrence of deficiency diseases (beri-beri and scurvy) in some areas of the war. A number of dry portable foodstuffs had been examined with a view to ascertaining those most suited to the cure and prevention of these diseases among the troops. Researches on anaerobic organisms isolated from cases of gas gangrene and other forms of gangrene, undertaken by the director in co-operation with Miss Robertson, had been completed by the latter, who had published a paper on the subject. She was now engaged in an investigation with the object of ascertaining whether an organism isolated by Dr. Penfold from cases of typhus fever conferred immunity against that disease. The calf lymph laboratory had been removed from Bushey to Hayle, Cornwall, where suitable premises had been acquired for a period of five years. The laboratory was under the direction of Dr. Green, and its removal liberated laboratories at Elstree needed for other purposes. The biochemical staff of the Medical Research Committee had occupied several laboratories in the Institute, and accommodation had also been placed at the disposal of the Ministry of Munitions. Mr. Bacot having successfully completed his work in Sierra Leone for the Yellow Fever Commission, returned to the Institute in October, 1915, and has been engaged in investigations on the bionomics of lice, with the object of devising a simple means of sterilizing clothing and preventing infection. Dr. Harden continues to act as deputy director during Dr. Martin's absence. The report was adopted, as was also the financial statement. It was announced that the council had elected Professor F. W. Andrewes, M.D., F.R.S., to be a member of the Governing Body in the room of Sir Henry Roscoe, and that it had also elected to be members of the Governing Body Sir John Rose Bradford and Sir E. Ray Lankester. Sir R. J. Godlee was elected a member of the council in the room of the late Mr. Pattison.

EFFECTS OF WAR ON POPULATION.

At a meeting of the Royal Statistical Society on May 16th two papers were read in which the changes which are occurring in the age distribution, birth-rate, and death-rate of the population of England and Wales were discussed. Sir J. Athelstane Baines showed that the relative number of the marriageable of both sexes has risen considerably since 1871, but that the number who marry is proportionally smaller. There was also, he said, a tendency to marry later, thereby shortening the productive period, and for the married to have smaller families. A great decline in the birth-rate had been the result.

¹ See A. J. Brown's Cantor Lectures, Royal Society of Arts, 1911.

especially since the beginning of the century. Owing, however, to a similar decline in the death-rate, the rate of natural increase of the population, though generally on the down grade, had been falling more rapidly of late, as the births had been declining in number more than the deaths. The distribution of the population by age and sex had been materially affected. In regard to age, the diminution of the number of children, which set in in the late Seventies of the nineteenth century, at first raised the proportion of adults in the prime of life, and at the most productive ages, and, so far, was economically to the good. It also tended to lower the death-rate, which is at its lowest during adolescence and early middle life. But, as the diminution continued, the people of middle life began to pass into the ranks of veterans, amongst whom the mortality is almost as high as at the beginning of life; the death-rate, therefore, tended to rise and the population to be older, not by reason of greater longevity, but from the lack of reinforcements from below. As the numbers at the productive ages grew smaller, the birth-rate tended to decline, irrespective of less or later marriage or the voluntary restriction of child-bearing. As the mortality of females is considerably lower than that of males, and as it is the men chiefly who leave the country for foreign parts, the balance of sex is slowly inclining more and more on the side of women. The falling off in the marriage-rate is more marked among women than among men, and one of the most important features in the present distribution of population is the rise in the ratio of unmarried women to bachelors. As a counterpoise, to some extent, for this phase in the national life, there is the much wider field now opening for women in occupations of all sorts. Sir Athelstane Baines concluded by expressing the opinion that the short supply of children was not entirely irremediable, since it might be somewhat counteracted by the measures now being put into force for the preservation of infant life. It might be hoped that a relatively greater number would reach maturity. The other paper, by Mr. J. W. Nixon, discussed the effect of war on national vital statistics, and was founded on a study of the effect of the Franco-Prussian war. The statistics of births, deaths and marriages in France and Prussia for the period 1868-73 were analysed, and it was shown that both countries experienced a rise in the death-rate in 1870 and 1871—the increase in the number of “civil” deaths being greater than the number of “military” deaths. This was especially marked in the case of France, the number of “civil” deaths being 437,000 more in 1870-1 than in 1868-69, while the number of “military” deaths was at the most 150,000. The rise in the death-rate was felt at all ages and shared equally by the two sexes. Not only the two belligerents but the three surrounding neutral States of Belgium, Holland and Switzerland all showed a period of maximum mortality in 1871. England and Wales remained unaffected. After the war, rapid recoveries set in in all countries except Prussia; the death-rate in France falling in 1872 to 22.0 per 1,000—the lowest on record. A serious fall in fertility was experienced by France and Prussia in 1871, and the three neighbouring neutrals similarly suffered a reduction in their birth-rates. There was a sudden decrease in marriage-rates in France and Prussia in 1870; it was partly made up in 1871 on the conclusion of peace, but the year 1872 was a “boom” year in both countries, the marriage-rate reaching the highest on record. The war had apparently no effect on illegitimacy, infant mortality, stillbirths, and the proportion of boys born to girls. Mr. Nixon considered corresponding figures for England, France, and Germany in the present war, though the data available are necessarily very limited. As in the Franco-Prussian war, all three countries are experiencing a serious fall in the birth-rate. The death-rate has not yet been seriously affected in England, the slight rise in 1915 being due to some extent to the bad winter and to an epidemic of measles. On the marriage-

rate, the effect has been the reverse of that in the Franco-Prussian war—a large rise having taken place last year. The theory advanced early in the war that it was having the effect of increasing the proportion of male births was found to be groundless, as was also the “war baby” theory. The serious effect which the war is having on the vital statistics of the nation was, Mr. Nixon said, to be seen in the fact that the “natural increase” of population in 1913 was 377,000. In 1915 it fell to 252,000, exclusive of deaths of soldiers abroad.

THE LIQUOR RESTRICTIONS.

THE regulations issued by the Central Control Board on February 17th, 1916, for the restriction of liquor traffic possess for members of the medical profession a more than mere academic interest, as has recently been demonstrated by proceedings which have been taken, and to which we shall refer. The regulations, speaking broadly, aim at restricting the number of hours daily during which intoxicating liquor may be supplied in licensed premises, and also provide additional restrictions on the sale of spirits. One of these latter restrictions is that “spirits to be consumed off the premises shall not be sold or supplied in or taken from any licensed premises in any bottle or other vessel not bearing a label showing the name and situation of the premises, or in any vessel of a capacity less than one reputed quart, or in any less quantity than one reputed quart, or in any open vessel.” To this, however, an exception is made where a person produces a “certificate in writing, dated and signed by a duly qualified medical practitioner, that the spirits are immediately required for medicinal purposes, and specifying the quantity of spirits required.” It will be noticed, therefore, that in order to satisfy this exception, and so entitle its recipient to purchase a quantity of spirits less than a reputed quart, the certificate must satisfy four conditions. It must be dated; it must state that spirits are required medicinally; it must limit the amount of the supply; and, finally, must be signed by a qualified medical practitioner. Now, in the proceedings to which we have already referred, which were taken for breaches of the regulations and which were heard by the Royton Petty Sessions on May 3rd, Dr. Forbes Kinnear of Royton had given one of his patients a certificate in these terms: “Please supply F. M. with whisky, gill quantities, weekly”; and beyond the doctor’s signature nothing further appeared on the certificate. The patient’s mother, by aid of this certificate, had for some weeks prior to the date of the proceedings obtained a gill of whisky almost weekly at a certain public house in Royton. Three charges were made. The publican was charged with having supplied less than a reputed quart of spirit for consumption off the licensed premises; the patient’s mother (S. M.) with carrying away the whisky; and Dr. Kinnear with aiding and abetting in the commission of the offence. Dr. Kinnear, who was represented by a solicitor instructed by Messrs. Hempson for the Medical Defence Union, admitted that the certificate in question did not satisfy the terms of the regulations, with which he was previously unacquainted. He stated that he and his colleagues had met and had agreed that they would charge a shilling apiece for these certificates, and intimated that for the future they would be signed and dated in conformity with the regulations. With this the case against him was dismissed without costs, and the publican was discharged with a caution. Without attempting in any way to criticize the general object with which these regulations were drafted, it would certainly appear unnecessary to put patients requiring small quantities of spirits for medicinal purposes and members of the medical profession to such inconvenience. Suppose a man requires, say, a dose of brandy in an emergency, is he or someone on his behalf, to be compelled to purchase a whole quart, or, as an alternative, to wait until a doctor can be found and a certificate complete in every detail given? Moreover, presumably the doctor would first have to

satisfy himself by seeing the patient that brandy was a medical necessity before he could give the certificate. No doubt if proceedings were taken in such circumstances the bench would consider that a technical offence merely had been committed. But it is to be regretted that those responsible for the conception of these provisions were unable to evolve a simpler method of meeting the point. Under the regulations a medical man must apparently certify each time a supply of spirits is purchased and not merely give a certificate that a weekly supply is necessary. We fail to understand what reason there can be for imposing this burden upon him.

THE FIFTH ARM.

DETAILS given in earlier issues of the physiological tests applied to would-be aviators in this country and in France showed that they were practically tests of "nerve." The training undergone by pupils in the French military aviation school at Buc near Paris, which turns out pilots at the rate of 160 a month, has been described in several recent publications. The pupils are drawn from all branches of the services, and receive a preliminary course of education in the theory of the subject that lasts three or four weeks. Then the pupil is taught to fly by one of two methods. Either he learns by himself, practising first on an aeroplane, nicknamed a "penguin," that can do no more than run along the ground, later he is given one that rises only five or fifteen yards in the air, finally he is put in charge of a normal full-powered aeroplane. Or, alternatively, he is taught to fly in a controlled machine, sitting in front of an expert pilot who controls the levers and steering as does the learner. This, it is said, is the more natural method of learning to fly. The pupil is up in the air with an expert pilot, and imitates his actions. With a beginner, the expert naturally takes complete command of the situation, and the pupil does little to regulate the flight. As the pupil acquires experience, the expert has less and less to do with the control of the flight. The first thing to be learnt is the art of landing. The flight is short and low, and the pupil's aim is to land at the required spot. Next he must learn to regulate the height at which he flies. All the flights taken are short, and are timed. After they have totalled twenty or five-and-twenty hours, the pupil is fit to go in for his qualifying tests. These consist in three triangular flights round three fixed points—three towns—and a couple of flights ascending to a height of 2,000 metres. Provided he has sound nerves, a strong constitution, and average intelligence, a man may become a pilot in thirty days. It is said that the art of learning to fly is best acquired slowly without undue hurry, and that the intellectual characteristics of the French as a race are just those required of aviators—intellectual concentration, rapidity of judgement, courage, and ease in grappling with the unforeseen. If a flier shows signs that his nerve is becoming affected, he is given furlough and ordered to rest, but Mr. Powell states that so great are the mental strain, exposure, and noise, that probably 25 per cent. of the aviators lose their nerve, and have to leave the service.

SCIENCE, INDUSTRY, AND MEDICINE.

THE annual meeting of the British Science Guild on Wednesday was made notable by an address by Mr. Andrew Fisher, the High Commissioner for the Australian Commonwealth, on the establishment of a national institute of science and industry in Australia. He defined science as the accurate, calculated application of experienced reason to practical problems. Early in the New Year Mr. Hughes, the Australian Premier, assembled representatives in Melbourne of all the universities, industries, and manufactures, and made it clear that the Government would lend its driving power to a movement for the establishment of a scientific institute. What he proposed was a central laboratory and bureau of

standards charged with the investigation of industrial problems. An Advisory Committee was appointed which reported within the incredibly short space of a fortnight in favour of a bold policy, recommending that the functions of the institute should be 'to collect and disseminate scientific information of all kinds, chiefly in connexion with the primary and secondary industries of Australia. Mr. Fisher also touched upon other recent scientific movements in the Commonwealth, and spoke at some length upon the Institute of Tropical Medicine at Townsville, Queensland, inaugurated in the beginning of 1910, and described in these columns not long afterwards. At the present time, Mr. Fisher said, an examination was being made of the blood conditions of children born and reared in North Queensland, with a view to proving whether the blood was normal or whether deterioration had taken place in the direction of anaemia which could be attributed to climatic conditions. As far as statistics had gone, Europeans had a better chance of life in the tropical portions of Australia than in the temperate zone of the continent. It was remarkable that Queensland—largely a tropical State—had at once the highest birth-rate and the lowest infantile death-rate; this was of vital importance to Australia, for it was hoped that it would decide the question of the climatic influence on the white man in the tropics. In proposing a vote of thanks to Mr. Fisher, Sir Alfred Keogh said that there were in the United Kingdom able, energetic, and brilliant scientific men, gifted perhaps above men of other countries in the quality of initiative, but they were fettered by tradition, and there was failure on the part of the nation to take advantage of their discoveries. He pleaded for the linking up of the universities with the industries. The industries should define the university syllabus for special research. In the profession of medicine this principle had been recognized in some measure, but he did not think it held true of any other profession. Speaking of his own department, he said that had it not been for the careful application of science before and during the war, the cases of typhoid fever among the troops—which now in France numbered only twenty-two—would probably have amounted to eighty or ninety thousand.

BENEVOLENT FUND FOR THE R.A.M.C. TERRITORIAL, SPECIAL RESERVE, AND NEW ARMIES.

A MEETING of medical officers of the Territorial, Special Reserve, and new armies to consider further the advisability of establishing, for the benefit of the widows and orphans of officers, non-commissioned officers, and men, some kind of benevolent organization similar to that which exists in the regular Royal Army Medical Corps, will be held at the Royal Army Medical College on Thursday, June 1st, at 2.45 p.m. The magnitude of the interests concerned is shown by the fact that there must be at least 9,000 medical officers belonging to the three categories, and from this some estimate may be formed of the number of non-commissioned officers and men. It is hoped that medical officers will take a lively interest in the proposal, and that as many as possible will attend the meeting on June 1st, when the Director-General, Sir Alfred Keogh, will be in the chair.

AT the meeting of the Medical Society of London on May 15th Mr. D'Arcy Power was elected president, Mr. Hugh Lett and Dr. W. J. Fenton honorary secretaries, and Dr. H. R. Spencer honorary secretary for foreign correspondence.

IN a note on the standard of vision in the army, published last week, the assumption was made that if vision equal to $\frac{1}{2}$ was enough for active service without glasses, $\frac{1}{4}$ with glasses would be sufficient for garrison duty. A correspondent has been good enough to inform us that this assumption is correct, and that an official memorandum was issued last year directing that men "who cannot be brought up to $\frac{1}{4}$ by means of spherical glasses should not be taken . . . for garrison duty."

Medical Notes in Parliament.

War Taxation and Finance.

THE second Budget of 1915 apparently required more parliamentary discussion than had been anticipated, and the latest proposals for obtaining more revenue from taxation have been placed before the Commons in two separate bills in order that more urgent matters may be dealt with at the earliest possible date. The first of these bills has now been disposed of, and the "new" taxes, such as the match duty and the entertainments tax, have now been cast in their final form, but the second has only recently been issued. This division of the Chancellor's proposals into separate bills may possibly absorb more Government time, but has obvious advantages in enabling the necessary administrative machinery to be set up immediately, thereby bringing the new duties into operation at an earlier date than would otherwise have been possible—an advantage not only to the Exchequer, but also to the traders concerned, who would probably prefer almost any trade conditions to those arising from uncertainty as to impending taxation.

We propose to deal with the second Finance Bill—Finance (No. 2) Act, 1916, as it will presumably become—but we may remark in passing that the substantial alterations effected in the mode of levying the match tax, made after the introduction of the first Finance Bill, afford an interesting illustration of the dilemma with which a British Chancellor is faced in proposing new taxes, that is, whether he is to rely mainly on the advice of the permanent officials, or whether he should obtain the opinion of the trade affected, and perhaps thereby run some avoidable risk of permitting an inkling of his proposals to become known in trade circles. Mr. McKenna—like previous Chancellors—seems to adopt the method of framing the system of levy to the best of his ability, trusting to our system of parliamentary discussion to afford ample opportunity for amending and elaborating the administration of the tax with the technical advice and co-operation which British taxpayers are not reluctant to supply where the tax is supported by the general sense of the nation.

Part I of the new bill deals with matters falling under the head of Customs and Excise, and is to a large extent devoted to increasing the duties on cocoa, coffee and coffee substitutes, and sugar, but also deals with customs and licence duties on table waters and cider. The duties on non-alcoholic beverages are to some extent intended to be a measure of justice to the tea merchants, whose commodity has previously borne a proportionately high rate of taxation. Section 10, which is of more interest than importance, may perhaps be mentioned. It imposes a 5s. duty on all "tinder boxes," or, as the bill, with that euphuism so often noticeable in statutory definitions of small articles, describes them, "mechanical and portable contrivances for producing a flame." Naturally the Government do not desire to see their latest tax rendered nugatory by an extended use of match substitutes, and a 5s. duty would seem an ample safeguard against that danger.

Section 11 is of direct importance to the medical profession, inasmuch as it carries into effect the proposed increase in the licences payable on motor cars by substituting a new scale of duties for that laid down in the Finance (1909-10) Act, 1910, and adopted hitherto. Most people will agree that the system of graduating the rates of duty according to the nature of the car—whether on the basis of horse-power, value, accommodation, or otherwise—is equitable, but an unfortunate feature of practically every operative system of graduation is that too much depends on the actual lines of division. For instance, if the car does not exceed 16-h.p., the new licence duty is £8 8s.; if it is between 16-h.p. and 26-h.p., the tax immediately becomes £18 18s. A further subdivision into intermediate groups, according to horse-power, would diminish the number of anomalous cases, but the practical advantages of basing the graduation on a division into groups probably stands in the way of a radical reconstruction of method by which alone all anomalies could be avoided—as, for instance, by the adoption of a system of percentage progression on each unit of horse-power. The actual phraseology of the section appears to suggest no

doubt as to the application of the rebate to the new scale of licences.

Part II of the bill deals with income tax—a more serious matter than even the substantial increase in motor licences. There are now three scales of rates: one applying to earned, another to unearned incomes, and a third scale, which is a modification of the earned rates in favour of soldiers and sailors. The super-tax rates are not raised, but the increase of the maximum income tax rate from 3s. for 1915-16 to 5s. for 1916-17 will probably affect the payers of the super-tax to an extent sufficient to prevent any lively feeling of gratitude on their part.

The ordinary income tax rates will apply as follows:

Total Income Not Exceeding	Earned Rate.	Unearned Rate.
£300	2s. 3d.	3s.
£500	2s. 3d.	3s. 6d.
£1,000	2s. 6d.	4s.
£1,500	3s.	4s. 6d.
£2,000	3s. 8d.	4s. 6d.
£2,500	4s. 4d.	5s.
Exceeding £2,500	5s.	5s.

It will be seen from the above that the graduation does not follow the same classification in each case. For instance, there is no special rate applying to earned incomes where the total income does not exceed £300, as in the case of the unearned rates, and the graduation of the latter rates stops at a point below that at which the classification of unearned income ceases. *Prima facie* one would have supposed that it would have been easier to graduate earned incomes according to a £300 limit than unearned incomes, seeing that the former are assessed directly upon the taxpayer and the latter are subjected to tax by deduction at the source. There may, of course, be insuperable difficulties which are not apparent on the surface, and no doubt an opportunity will arise during the debates for explaining their nature. One would certainly be inclined to suppose that if equity requires a graduation at the £300 limit in one case it would also call for a graduation at the same point where earned incomes are concerned.

Section 13 continues the operation of the relief afforded by the second Finance Act of 1914, the principle of which is that where a practice has suffered owing to the war, the average of the three previous years may be discarded in favour of an average of the two previous years and the current year, but the subsequent section grants a mode of relief which is simpler in its operation, and—where it applies—likely to be more fruitful in its results. It provides that where the "actual income" of a taxpayer from all sources for the year of assessment is less by more than 10 per cent. than the income on which he has been assessed and charged—as it may very well be if he is paying tax on an average of previous receipts, and is adversely affected by the war—then he shall be entitled to repayment of tax paid by him to the extent necessary to reduce that sum to the amount of tax on his "actual income." The remarks we have already made as to the tendency of our methods of taxation to sacrifice a logical application of equitable principles to practical simplicity apply with greater propriety here than even to the classification of motor cars for licence purposes. If this relief be given to a taxpayer whose income has fallen 11 per cent., it is difficult to see how in strict equity some measure of relief can be refused to one whose diminution is calculated at 9 per cent., but in point of fact, if this particular question be regarded in the light of the last Finance Act, the taxpayer would appear to have cause for gratitude rather than for complaint. In that Act it was provided that where the diminution exceeded 10 per cent. some percentage only, calculated by reference to a statutory scale, of the additional tax paid was repayable. So that, although there is no remedy where the percentage is less than 10 per cent., the complicated repayment by application of a scale is swept away to the clear advantage of the taxpayer. In other words, Section 19 of the present bill constitutes a desirable extension of a previous form of relief, and in such circumstances the "hard case" of the man who still remains outside the 10 per cent. rule—and such cases cannot be very grievous—is not likely to receive much practical legislative sympathy.

The question of applying war rates of taxation to officers in the army and navy has received, and without question will continue to receive, a considerable amount of parlia-

mentary attention. It will be remembered that for 1915-16 the relief given on grounds of military or naval service was restricted to the application of pre war rates of duty and abatements where the *total* income did not exceed £300. This allowance still holds good, but the bill adds a more precise definition of the persons who can claim this form of relief, and extends the allowance beyond its original scope. The new rates are as follows:

Where the total income does not exceed	£300	...	9d.
"	"	£1,000	2s. 1d.
"	"	£1,500	2s. 5d.
"	"	£2,000	2s. 9d.
"	"	£2,500	3s. 3d.
"	exceeds	£2,500	3s. 6d.

It will be seen, on comparing these figures with those in the ordinary earned income scale, that there is a reduction which should be quite perceptible, but perhaps the most striking feature is the wide gap between the £300 and the £1,000. The effect of this is to render the section almost inoperative to that very considerable body of officers who, in present circumstances, have a taxable income of between £300 and £500, inasmuch as they receive an allowance of 2d. in the £ only, although the relief is substantial where the total income is greater, gradually reaching a maximum of 1s. 6d. in the £. Bearing in mind, also, the very sudden rise in the rate which takes place when the £300 limit is crossed, we suggest that there are almost overwhelming arguments in favour of a special rate for total incomes between £300 and £500—say, for instance, 1s. 9d.

Another important matter in this connexion is the definition of the class of taxpayer to whom this relief is to apply, and we therefore make no apology for quoting the relevant portions of the two sections concerned in *extenso*:

§ 20. (1) Where any person who during the current income tax year has served or is serving as a member of any of the naval or military forces of the Crown or in service of a naval or military character in connexion with the present war for which payment is made out of money provided by Parliament, or in any work abroad of the British Red Cross Society or the St. John Ambulance Association, or any body with similar objects, claims, etc.: and

§ 21 (1) provides that a person shall not be deemed to have served as a member of the naval or military forces of the Crown unless he has served—

- (b) In the army, either with the colours or as an officer on full pay or at a rate of pay which appears to the Income Tax Commissioners concerned, after consultation with the Army Council, to be equivalent to full pay, and either out of the British Islands or for at least one month continuously in the British Islands.

For our present purposes these sections are important because of the large number of practitioners who are engaged on military hospital work in this country. Such work interferes seriously with the ordinary conduct of their civil practices, and frequently involves them in a considerable amount of additional work at a time when they are endeavouring to supply a lack of medical assistance and surgical skill arising from the absence on military service of other practitioners in the same locality. Whether or not such hospital remuneration will be taxed at the special reduced rate will depend on the final form taken by the two sections under consideration. Without attempting to decide whether, in such a case the practitioner would claim to be a member of the forces of the Crown, as defined by Section 21, it appears to us that he would be within the words of Section 20 "in service of a naval or military character in connexion with the present war, for which payment is made out of money provided by Parliament." If there be any doubt on the point it is to be hoped that the coming debates will dissipate it, or lead to the adoption of some other form of words to meet the case.

The remainder of the income tax sections are severely technical and not of substantial importance, with the exception of the somewhat complicated Section 23, which in effect places a maximum income tax of 3s. 6d. so far as the United Kingdom is concerned on colonial income which has already suffered colonial income tax at its source.

Part III of the Bill deals with the excess profits duty, and after increasing the levy for the second war year to 60 per cent., is concerned mainly with questions arising out of the assessments on shipping and munition businesses. This part of the Bill is to our readers a matter of general rather than personal interest.

War.

The Military Service Bill.

The consideration of the Military Service Bill has occupied much of the time of the House of Commons. The report stage was concluded on the evening of May 16th, and the bill was read a third time by 250 to 35. A number of amendments have been made of the exact effect of which it is difficult to judge until the bill has been reprinted. A great deal of interest was shown in an amendment, proposed in the interest primarily of the small shopkeeper, providing for exemption if it is proved that the man is the sole head of the business; that there is no other person available to carry it on; and that he has a wife and children depending upon it. Mr. Duke suggested that the wording of the exemption should be "On the ground that a man is carrying on business which is a means of livelihood to himself and not less than three other persons depending on him, and which cannot be continued without his services." Mr. Long undertook to issue an instruction under Section 5 to the tribunals, and this undertaking was accepted.

British Prisoners in Germany.

On May 11th Mr. R. McNeill asked a question as to statements made by Mr. Hanson, who has returned to England after eleven months of internment in Germany. The statements were to the effect that not more than 3½ oz. of meat and ½ lb. of bread, composed of a mixture of inferior rye, potatoes, and straw, together with coarse vegetable roots such as were usually fed to cattle, formed the daily allowance of civilian prisoners in Germany, and that the conditions for military prisoners were even worse. Mr. McNeill also asked whether attention had been called to Mr. Hanson's statement that he had frequently heard Mr. Gerard tell starving British prisoners that they had their own Government to thank for their sufferings; and whether any suggestions had been received by the Government from Mr. Gerard as to measures that might be taken to secure better treatment for British prisoners in Germany. Lord Robert Cecil said that quite recently the Government had asked the United States Ambassador in Berlin to inquire as to the quantity and quality of the food at present being supplied at Ruhleben. The United States Ambassador had been indefatigable in his efforts to improve the conditions obtaining in the prisoners' camps in Germany, and the country was most grateful to His Excellency for what he had done. In reply to supplementary questions, Lord Robert Cecil said that he hoped the statements quoted exaggerated the state of things in the camp. He would like to be able to say that such things never occurred, but the Government's information, speaking generally, had been that, although the food was insufficient, it was not so bad as described in the question.

Invalid Prisoners in Switzerland.

On May 10th Lord Robert Cecil said that the agreement under which German and British prisoners of war would be sent to Switzerland, together with a list of the diseases which would qualify for internment in that country, would be circulated very shortly, and Mr. Tennant said that the medical officers in prison camps in Great Britain were preparing a list of those invalid prisoners of war who, in their opinion, should be sent to Switzerland. In reply to questions by Mr. Malcolm, on May 15th, Lord Robert Cecil said that he was unable to state the exact date on which the Swiss Medical Commission to take evidence as to German prisoners in this country qualified by illness to be sent to Switzerland would reach this country. It was understood that the first batch of British prisoners would be sent to Chateau d'Oex and its neighbourhood, and it was hoped that the first batches of prisoners might leave this country and Germany at the end of May.

Jaw Injuries.

Mr. Pennefather, on May 11th, asked how many hospitals there were in this country in which jaw injuries suffered by soldiers could be treated by general surgeons and dental surgeons acting in collaboration, and how many had been established by the French authorities. Mr. Tennant replied that in all hospital centres arrangements had been made for jaw injuries to be treated by general surgeons and dental surgeons acting in concurrent

collaboration. He was not able to say how many special hospitals had been established in France.

Medical Examination of Recruits.—On May 9th Mr. Ashley asked whether it was the case that until recently Southern Command Orders included an order to medical officers of units to at once medically examine all men joining to ascertain whether they were fit for general military service, but that a short time ago medical officers were instructed not to examine recruits, and that a fortnight ago an order was issued in the command that no medical inspection should take place except for infectious diseases. He wished to know whether medical examination by medical officers attached to units would be resumed, so as to avoid waste of public money by inefficient soldiers being retained for a considerable time in the public service. Mr. Tennant said that orders in the Southern Command had been changed in this respect. Previous to the adoption of the system of examination of recruits by selected boards of R.A.M.C. officers, a large number were examined in the first instance by civil medical practitioners, and it was considered necessary that these men on joining their units should be re-examined by the regimental R.A.M.C. officers, as the civil medical practitioners had not always the necessary experience in examining recruits. As all recruits were now examined before enlistment by selected recruiting boards, the second examination by the regimental R.A.M.C. officer was not considered necessary, except for the purpose of detecting infectious disease. As it was unnecessary, public money and public time were saved by its abolition. In reply to a supplementary question, Mr. Tennant said that he presumed the order extended beyond the Southern Command. Mr. Billing, on May 11th, called attention to the fact that men in Hertfordshire were called upon to attend a medical board at Bedford, involving the loss of a day's work and travelling expenses, and asked whether the War Office would make arrangements for a medical board to attend one day a week or one day a fortnight at the chief town at each of the parliamentary constituencies of Hertfordshire. Mr. Tennant said that the question of placing the medical board for Hertfordshire in a more central position was under consideration, but it was impossible to obtain the services of sufficient medical officers to arrange for medical boards to visit the chief towns of all constituencies. If a man concerned was called to the colours, he received a free warrant. If he desired, as it was natural he should, to be examined by a medical board before he was called up, then he was travelling as an ordinary citizen, and was not given a free warrant. Mr. Tennant stated, on May 15th, that no man known rightfully to hold a certificate of rejection on medical grounds issued by an authorized official would be required to be re-examined unless there were reason to believe that his medical disability was temporary or of a nature which did not preclude his employment in some form of military service. There was no form of certificate which exempted a man from all forms of military service. A man might be employed in other categories than general service. He promised, however, to see if some means could be devised for granting a certificate showing in suitable cases that a man was absolutely rejected. On May 15th Mr. Tennant said that he was inquiring into the allegation that in some places married men had been refused facilities for submitting themselves to medical examination in order to ascertain at the earliest possible date whether their services would be required by the army.

Medical Boards.—In reply to Sir Ryland Adkins, on May 15th, Mr. Tennant said that the medical boards by which men previously rejected for the army on medical grounds would be re-examined were those appointed and working in each recruiting area. The presidents were appointed by the War Office and the members in the commands. In reply to a further question as to the propriety of having at least one civilian doctor on each board in view of the fact that the examinations were re-examinations and awakened a great deal of public interest and anxiety, Mr. Tennant said that the War Office was utilizing the services of a large number of civilian doctors. The number of the boards would be sufficient to ensure adequate and proper examination of each individual.

Khaki Helmets.—On May 15th Mr. Tennant told Mr. Malcolm that the Commander-in-Chief of the British Expeditionary Force in France reported that all existing steel helmets were provided with covers or rough paint. The question of which method was the more efficacious was engaging his attention, but he was not in a position to make a recommendation.

Army Dental Treatment.—On May 10th Mr. Tennant informed Mr. Pennefather that he was not able to say how many qualified dental surgeons had been recruited for combatant service, but it was true that qualified dental surgeons were still being recruited for combatant service. He added that full provision for dental surgeons for the army had been made, and that all demands for such service for the troops both at home and abroad had been supplied. There was a large number of applicants for dental commissions, and no difficulty was anticipated in meeting any demands that might remain. The War Office had no information as to the number of dental surgeons employed by the French Government to look after the teeth of French soldiers, nor those employed in the Canadian forces.

Petrol Supplies.—On May 15th Sir H. Craik asked the President of the Board of Trade a question as to the dearth of petrol for necessary purposes, such as the requirements of the medical services in country districts

where long distances had to be traversed; and whether regulations would be made to secure that the supply for such necessary purposes should not be interfered with by the use of petrol for purposes of luxury and amusement. Mr. Runciman said that he was aware of the position with regard to petrol and had appointed a Committee to consider what measures were necessary to secure adequate supplies for the purposes of the war and other essential needs, including medical services. The Committee was now inquiring into the whole subject. In reply to a further question by Mr. Cathcart Wason as to whether the regulations of the Board of Trade with reference to railway trains had not accentuated the dearth of petrol by leading to the increase of private motor cars, Mr. Runciman said that he had been making inquiries, but could not find that there had been any increase in the use of private motor cars. So far as he could ascertain, the number in use was lower than before. On May 16th Mr. Cathcart Wason asked whether it would be desirable and practicable to draw a distinction between cars used for business purposes and cars used for pleasure and luxury, so that petrol could be obtained at a more reasonable rate for professional and business purposes. It was, he said, practically impossible for doctors to obtain petrol, owing to its scarcity. Mr. McKenna repudiated responsibility for this, stating that it did not come within the purview of the Home Department.

Motor Car Duties.—On May 10th Mr. Cathcart Wason asked the Chancellor of the Exchequer whether he was aware that the increased taxation of motor cars used by doctors pressed on the medical profession, and that the public interest suffered; and whether he would take into consideration the desirability of making a further concession, with especial consideration to the increased price of petrol and the difficulty of obtaining it. Mr. McKenna replied as follows: "As I have already stated, I am considering all questions relevant to the proposed increase of motor car licence duty; but I must add that it would be difficult to justify any change which would give members of the medical profession—who only pay half duty—a greater proportional preference over other users of motor cars."

Science and Education.—Sir Philip Magnus asked the Prime Minister on May 9th whether, having regard to the general demand for an exhaustive inquiry into the present educational system, particularly with regard to the claims of science to occupy a more important place in the curriculum of schools, he was able to make any statement as to the proposal submitted to him for the appointment of a Royal Commission to consider and to report upon the question of the organization of education in this country. The Prime Minister replied that when the Government was in possession of the results of the various inquiries set on foot it would be possible to decide whether any useful purpose would be served by setting up a Royal Commission. In reply to Mr. Lynch, he expressed his willingness to receive a concrete suggestion for some better method of inquiry than by a Royal Commission.

Dope Poisoning.—In reply to a question by Mr. Bowerman, on May 11th, Mr. Brace, Under Secretary, said that the Home Office had been in constant communication with the departments concerned, and it was understood that the arrangements set on foot some time ago for securing an adequate supply of a satisfactory dope free from tetrachlorethane for use in aircraft works were now approaching completion; it was hoped that the approved dope would shortly be manufactured in such quantities as to meet all requirements. The use of any other non-poisonous dope prepared by private makers must depend on its suitability for aircraft purposes, a matter for the War Office and Admiralty to decide.

Old Age Pensions.—In a written reply to Mr. Wing, on May 9th, Mr. Montagu stated that the total number of old age pensions payable on December 31st, 1915, was 982,384, of which 364,464 were to men and 617,920 to women, the numbers payable at the several rates being:

5s.	4s.	3s.	2s.	1s.
928,085	19,540	19,986	9,697	5,076

THE WAR.

LICE.

DR. ALBRECHT HASE of Jena, who was deputed by the German War Office to study the plague of lice on the eastern front in the summer of 1915, has reported.¹ As regards susceptibility to the bite of the body louse, inquiry among nearly a thousand individuals established the existence of the following groups: (a) Those whom lice do not frequent although they are in the midst of lice; (b) persons who are attacked by lice and continue to be susceptible to their bites over long periods; (c) those who are susceptible to begin with, but cease after a time to be affected by the bites although they still harbour the parasites; and (d) individuals who have harboured lice for long periods but have never been affected by their bites. No case in which insusceptibility had been replaced by susceptibility was met with.

Groups (c) and (d) are especially dangerous from the hygienic standpoint since they do not suffer any inconvenience, and consequently have less incentive to free themselves from the vermin. No relation between susceptibility to the bites of fleas and of lice could be made out. One hundred and eighty-one substances were tested for their capacity to protect against infection with lice; the great majority were quite useless, and Dr. Hase comments caustically on the fraud perpetrated by the vendors of these valueless preparations, sold under high-sounding names, at exorbitant prices. The conclusion arrived at is that even the most active substances known, in the largest doses, will not protect the person from lice for more than one or two days. This is confirmed by Galli-Valerio,² who finds that lice will even bite through skin covered with substances which cause their death. Some active compounds, such as, for instance, paradichlorobenzol, caused burns of the skin, even when the bags containing it were worn outside the shirt; others, such as clove oil, are too expensive.

There is no clear evidence that close contact with horses protects from or predisposes to lice, nor has any connexion been found to exist between perspiration, hairiness of the body, or previous infectious disease to susceptibility to lice. It is, however, asserted that underclothes heavily soiled with sweat are a protection as compared with clean garments; the explanation suggested is that the soiled garments are comparatively impervious to air and moisture, so that when the wearer works hard in warm weather the atmosphere between the clothes and the skin becomes too close and warm even for the louse. The men had rediscovered for themselves the fact that ants are antagonistic to lice, and some buried their shirts in ant-heaps in order to free them from the pest. When troops are stationary lice can be kept under only by unremitting attention to billets and clothing, and with the co-operation of every individual; where troops are continually being moved any considerable measure of success is impossible. Friedmann³ has investigated the various procedures for killing the body louse and its nits on clothes and in rooms. Normal nits incubated at 32° C. in an atmosphere containing 40 to 60 per cent. of moisture hatched this way in eight to twelve days. Exposure to air at a temperature of 76° C. for five minutes killed both lice and nits wrapped in wool. He considered that "insect powders" were valueless, and found that lice sought out woollen materials but avoided silk, on which they would not deposit nits. He recommends the vapour of carbon disulphide for killing lice and nits in clothes and rooms. The fluid is exposed in a thin layer in flat dishes, 100 c.cm. being allowed per cubic metre of room space and allowed to act for ten to twelve hours. Clothes are well penetrated, and even furs and skins, which are soon damaged by a temperature of 80° C., are not harmed. Airing soon removes the smell, but it is to be remembered that the vapour cannot be breathed with impunity, and that there is danger from a naked flame. Although carbon disulphide is dearer than sulphurous acid it is to be preferred owing to its volatility and because it is harmless to clothes.

DISINFECTION BY HOT AIR.

In the earliest forms of disinfectors for clothes hot air was used. Probably the best apparatus of the kind was that devised a good many years ago by Ransome. It was a chamber lined with non-conducting material, and had an outlet at the top. The air was heated by gas jets, the temperature of the ingoing hot blast being kept constant by an automatic regulator. The best working temperature was found to be 255° F. (124° C.), which was the highest that could be used for any length of time without risk of singeing cotton goods. This, and the fact that the heat penetrated bulky articles slowly, were the chief objections to it.¹ Hot air, however, is still used for leather articles, india-rubber, furs, and books; for the disinfection of other articles of clothing it has been almost completely displaced by moist heat. Rautmann² now claims to have obtained highly satisfactory results by means of a current of dry hot air in an apparatus devised by Vondran. A current of air heated by passing over an electric radiator is propelled into the disinfecting chamber under pressure by an electric motor; the hot current enters at the bottom of the chamber and is drawn out from the top, returning into the blast again. This circulation of the air reduces to a minimum the amount of heat required. To test the penetrating powers of the hot air under these conditions rolls of cotton-wool weighing $\frac{1}{2}$ lb. and 6 in. in diameter and 8 in. long, were exposed in the apparatus for fifty-two minutes; maximum thermometers placed in the centre of the rolls recorded temperatures of 150° C. and upward. By way of control, similar rolls of cotton-wool were exposed to the same temperature in an ordinary hot-air oven, without any special device for producing a current; no rise in the thermometers in the centre of the rolls occurred. The effect of moisture on the penetration was tested with rolls of cotton-wool which weighed 2 lb., and had a diameter of 11 in.; no difference due to the moisture was detected. Leather articles, such as boots and gloves, showed no damage after an exposure of thirty-five minutes to hot air at 178° C., which killed anthrax spores on silk threads. Boots were undamaged, even when they had been soaked in water prior to exposure in the apparatus.

Rautmann's conclusions seem to be based on laboratory experiments, for a small bundle of cotton-wool is a very different thing from a blanket or great-coat, so that although the results are promising, he does not seem to have established the practical value of the apparatus he recommends. If his statements prove even approximately correct, it might prove convenient for the destruction of lice.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

LIEUTENANT AINSLIE BOOTH, R.A.M.C., whose death in action was noted last week, was killed on April 30th. He was the son of the Rev. Dr. Booth, of Cape Town, South Africa.

Died on Service.

Captain N. J. L. Yellowlees, of the Canadian Army Medical Corps, was reported to have died on service, in the casualty list published on May 11th.

Third-class Assistant Surgeon Joseph Valentine Fernandez, of the Indian Subordinate Medical Department, died on active service in Mesopotamia on December 1st last. He was born on January 22nd, 1885, attained warrant rank in the Bombay Army on December 31st, 1906, and was promoted to the third class on December 31st, 1911. Prior to the war he was stationed at Almadnagar.

Wounded.

Captain A. S. Plant, R.A.M.C., temporary.
Captain O. L. V. de Wesselow, R.A.M.C., temporary.
Captain H. F. N. Scott, R.A.M.C., temporary.
Captain F. B. Winfield, R.A.M.C., temporary.
Captain E. J. Blair, R.A.M.C.(T.F.).

Missing.

Captain W. R. O'Farrell, R.A.M.C.

DEATHS AMONG SONS OF MEDICAL MEN.

Allatt, H. T., Colonel Royal Irish Rifles, late Duke of Cornwall's Light Infantry, son of the late Dr. C. J. R. Allatt, died

¹ Notter and Firth's *Hygiene*. Third edition, 1908, p. 745.

² *Centralbl. f. Bakt.*, vol. lxxvii, p. 50.

suddenly on May 8th at Belfast of heart failure, following his exertions in Dublin during the rebellion. He had served in South Africa, and held the Queen's medal with four clasps. He had retired from the army for some years, but rejoined when the war broke out, and was attached to the Royal Irish Rifles. He was on duty in Dublin in charge of an armoured car.

Beatty, Eric Edge, Lieutenant Connaught Rangers, third son of Dr. Wallace Beatty, physician, Adelaide Hospital, Dublin, killed in action on April 29th, 1916, aged 22. He was educated at St. Columba's College and at Trinity College, Dublin, where he was a fourth-year medical student and half-back in the university Rugby fifteen. He got a commission in the 6th Service Battalion of the Connaught Rangers in September, 1914, and was promoted to lieutenant on February 11th, 1915.

Collins, N. H., Second Lieutenant Royal Inniskilling Fusiliers, only son of Dr. Collins of Laghey, county Donegal, killed in action. He was born in May, 1889, educated at Mountjoy school, Dublin, and got his commission on March 15th, 1915.

McConaghey, Charles Jack, Lieutenant Black Watch, son of the late Colonel John McConaghey, I.M.S., killed in action on April 21st-22nd. He was educated at Allhallows, Honiton, and at Bradfield College, Berkshire, and entered the Royal Military College, Sandhurst, in August, 1914. He got his commission on December 16th, 1914, went to Flanders in May, 1915, was wounded in the shoulder at La Bassée in September, and rejoined last February.

Wyatt, William Herbert, Second Lieutenant East Yorkshire Regiment, only son of the late Dr. W. T. Wyatt, was killed in action on May 4th. He was educated at Marlborough and at Exeter College, Oxford, where he graduated as B.A. He represented both his school and his college in the football and hockey teams. He was admitted a solicitor in July, 1913. At the beginning of the war he enlisted in the Artists Rifles, and got a commission on April 23rd, 1915.

Captain Randolph Noel Churchill Murray, Royal Inniskilling Fusiliers, reported missing, is the son of G. M. P. Murray, F.R.C.S.I., of Dublin, and a second-year medical student at Trinity College. Second Lieutenant George Malone, Royal Irish Regiment, wounded in the Dublin rebellion, is also a second-year medical student at Trinity College, Dublin.

NOTES.

Mr. J. LYNN THOMAS, C.B., F.R.C.S., Surgeon to the King Edward VII Hospital, Cardiff, has been appointed Consulting Surgeon to the Western Command, with the temporary rank of honorary Lieutenant-Colonel, R.A.M.C. Mr. Lynn Thomas served with the Welsh Hospital in South Africa with the rank of Captain, and received the medal with three clasps. He retired in 1913 with the rank of Major, R.A.M.C.(T.F.).

MESOPOTAMIA.

The Joint Executive Committee of the British Red Cross and the St. John Ambulance Association has received an interim report from its commissioner, Mr. Ridsdale, who arrived in Bombay on April 4th. On his way to Bombay he stopped at Aden, and was able to supply some stores of which the medical officers were in need, and cabled to London, with the result that ice machines, disinfectors, and stores were at once dispatched to Aden. At the same time he was able to arrange with Dr. Ruffer in Alexandria and with the Red Cross commissioner in Egypt to supply additional stores and green vegetables as required. Mr. Ridsdale on his arrival in Bombay seems to have found that the Red Cross voluntary aid work was in an unsatisfactory state, and hampered by the need for constant reference to Simla. At his suggestion the Executive Committee has appointed Major Hepper, agent for the Great Indian Peninsular Railway, to be its commissioner at Bombay. Mr. Ridsdale reported that Lady Willingdon's War Supplies organization was extremely well managed by a committee of business men, and the Executive Committee has arranged to establish a branch in Bombay of an "All India" effort to help the Red Cross side of Lady Willingdon's organization. Owing, apparently, partly to Mr. Ridsdale's efforts in Bombay the audit office there is being prepared, by direction of the Government of India, as a military hospital for white troops. Mr. Ridsdale arrived at Basra on April 16th, and in response to his request a large quantity of stores have been sent out from this country to that port, consisting chiefly of water and air beds, ice machines, wheeled chairs, and medical comforts. It is reported that three motor boats sent out by the Executive Committee have reached Basra, as also two sent by the Scottish Branch of the Red Cross; five other boats are on their way out, and fifteen more will be ready by the end of May. Their arrival is anxiously awaited, as the great difficulty has been in respect of transport. The Executive Committee is also preparing a shallow draught hospital ship for use on the Tigris, very similar in construction to the three hospital ships at present under construc-

tion by the Government for river service. It will be remembered that Mr. Ridsdale is a member of the Government Committee of Inquiry into the treatment of the sick and wounded in Mesopotamia, the other members being General Bingley and Sir William Vincent.

SIR JOHN NIXON'S DISPATCH.

CTESIPHON AND KUT.

On May 10th the War Office published a dispatch from General Sir John Nixon, dated January 17th, 1916, on the operations in Mesopotamia during October, November, and December, 1915. This dispatch contains the following references to the work of the medical department:

"The medical services have had to face very trying and unusual conditions. On more than one occasion the number and severity of the casualties have thrown the greatest strain on them, but the organization and efficiency of the arrangements have ensured as speedy an evacuation of the wounded as the means placed at their disposal permitted. In this connexion I wish to bring forward the name of Surgeon-General H. G. Hathaway. . . . The British General Hospital has throughout been in charge of Lieutenant-Colonel D. J. Collins, R.A.M.C., whose zeal, energy, and organizing power have rendered it a model hospital of its kind. Credit is also due to Lieutenant-Colonel G. B. Irvine, I.M.S., for his devoted and careful supervision of the Indian General Hospital."

At the end of the dispatch the names of nineteen officers are specially mentioned; among them is Captain W. H. Hamilton, I.M.S.

HONOURS.

The names of the following officers are included in the list of officers who have been awarded the Distinguished Service Order or the Military Cross in a special supplement to the *London Gazette* of May 16th:

D.S.O.

Temporary Captain Robert McCowan Hill, R.A.M.C. (attached 2nd Battalion Argyll and Sutherland Highlanders), for conspicuous gallantry and devotion to duty. He went to an area which was under intense bombardment, amputated the leg of a wounded officer, and attended to other wounded under most difficult and dangerous circumstances. Finally, he accompanied two stretcher cases back under shell-fire.

Captain R. McCowan Hill graduated M.B., Ch.B. Glasg., and practised in Upper Tooting, S.W., before the war.

Military Cross.

Temporary Captain James Lennox Stewart, M.B., R.A.M.C. (attached 1st Battalion Gordon Highlanders). For conspicuous gallantry and devotion to duty on several occasions when tending the wounded under heavy fire. On one occasion he rallied men, and set a splendid example of coolness and bravery.

Captain J. Lennox Stewart, who received his medical education at Guy's Hospital, took the degrees of M.B., B.S. Lond. in 1912.

Serbian Orders.

The King has granted unrestricted permission for the wearing of the Order of St. Sava, of the class indicated, conferred by His Majesty the King of Serbia on the following members of the Royal Army Medical Corps Mission to Serbia, March to June, 1915:

2nd Class: Temporary Colonel William Hunter, C.B., M.D., F.R.C.P.

3rd Class: Lieutenant-Colonel George E. F. Stammers.

4th Class: Captain Sydney W. Lund, M.B., Mr. William W. O. Topley (late Captain R.A.M.C.).

5th Class: Captains: Norman Cameron, M.B., Edward S. Walls. Temporary Captains: John M. Clements, M.D., Bernard C. Ewens, Alexander K. Forbes, M.B., Charles M. Forster, J. McAdam Hill, M.B., Samuel E. McClatchey, M.B., Charles R. Nicholson, Thomas H. Ravenhill, M.B., Hugh Y. Riddell, M.B., John H. V. Scott, M.B., Philip J. A. Seccombe, M.B., Bryce McC. Smith, M.B., Charles E. H. Smith, Robert H. Spittal, M.B., Lewis A. Walker, M.D., Gerald Whittington, M.B., John S. Williamson, William M. Will, M.B., and Mr. Francis F. Brown (late Lieutenant R.A.M.C.).

Indian Army.

In the *London Gazette* of May 2nd, in a list of Indian officers on whom the Indian Order of Merit had been bestowed, with effect from January 1st, for gallantry and distinguished service in the Dardanelles, was the name of 1st Class Subassistent-Surgeon Ghaus Muhammad, I.S.M.D.

A Correction.

In the list published in our issue of May 6th, p. 670, of those upon whom the honour of C.M.G. had been conferred, the name of the undermentioned officer should have appeared as follows:

Major (temporary Lieutenant-Colonel) Creighton Hutchinson Lindsay, M.D., R.A.M.C.(T.F.).

England and Wales.

THE WELSH NATIONAL MEDICAL SCHOOL.

A TREASURY minute dated April 18th, 1916, on the reports of the Advisory Committee on grants to universities and colleges and of the departmental committee on the National Medical School for Wales, together with copies of these reports, has been issued as a White Paper.

It appears from a memorandum of February 26th, 1914, that the grants to the University of Wales and its three constituent colleges from the Treasury amounted to £31,000, and from local authorities to £2,000. It is proposed that the grant by the Treasury should eventually be increased by £11,000, and the grants by local authorities by £9,000. Pending the report of the Royal Commission recently appointed to inquire into the organization and work of the university and colleges, and into the relations of the university to the colleges and to other institutions in Wales providing education of a post-secondary nature, the Treasury is prepared to concur in the recommendations of the Advisory Committee on university grants. Provided that, pending the reconstitution of the university, the new grants are applied wholly to meet existing liabilities, and conditionally on the continuance of the grant of £2,000 at present contributed by the Cardiff local authority, the Treasury undertakes to include in the Estimates for 1916-17 an additional sum of £5,500 for the first year of the new grants. Of this sum £1,000 will be allocated to the university, £1,125 to Aberystwyth, £1,125 to Bangor, and £2,250 to Cardiff. The Advisory Committee recommended that this State grant should be contingent upon a further sum of £3,500 being raised from the rates during the year in addition to the rate aid already given by Cardiff, but the Treasury is willing to waive this condition during the war. After its termination, however, further State assistance will be contingent upon its fulfilment. The Treasury will then be prepared to pay £500 over and above £5,500 for each further £500 raised by the local authorities until the total additional grant from the Exchequer to the university and the colleges reaches £11,000 a year. The Treasury also concurs in the recommendation that in future the contributions by local authorities should be regarded as support of the university as a whole, and should be allocated between the university and the colleges in the proportions indicated above.

National Medical School.

Subject to the acceptance of the future decision of the Government on the report of the Royal Commission with regard to the control of the National Medical School, and of the postponement until after the war of such part of the work on the new buildings as has not been specifically sanctioned by the Treasury, it will be prepared in due course to make a maximum grant in respect of the medical work of the college on certain conditions. The report of the Advisory Committee, dated February 26th, 1914, contains the following passages:

The most important claim is that for the extension of the medical school. Cardiff is the only centre in Wales where an effective medical school can be conducted, and at the last quinquennial distribution a grant of £1,500 a year was made by the Treasury to enable the College to found a medical school giving instruction in the preliminary and intermediate subjects. The College now desires to complete its medical school by undertaking the final and clinical subjects which hitherto students have had to study either in London or elsewhere. If such a complete school is to compete successfully with the large and well-equipped schools of medicine already in existence elsewhere, and if it is to provide a fitting medical education for students of the Principality, it must, in our opinion, be conceived on the most modern line and be based on the "unit" system, as described in the recent report of the Royal Commission on University Education in London, with salaried heads, graded assistants, and well-equipped laboratories. The control of the departments in the clinical subjects and the appointment of the staff in charge of those departments must be secured by the close co-operation of the academic authorities with the hospital authorities. The financing of a medical school on these lines is a very serious undertaking.

Even should the establishment of a modern clinical

school with a full equipment of medical, surgical, and gynaecological "units" be delayed, additional income would still be needed for the salaries and maintenance of the departments of science ancillary to the study of medicine and surgery and for increasing the efficiency of the instruction in the intermediate subjects. Our estimates of the immediate needs are therefore in the main unaffected by the larger issue we have been obliged to raise.

The Departmental Committee, in a report dated December 9th, 1914, gives the following estimate of the additional sums which would be required for the first ten years:

	£		£
1st year ...	4,565	6th year ...	9,365
2nd " ...	6,490	7th " ...	8,865
3rd " ...	9,240	8th " ...	8,490
4th " ...	8,990	9th " ...	8,240
5th " ...	9,990	10th " ...	8,115

In its previous report the committee had expressed itself strongly of opinion "that a school of medicine which aims at being national in its character must command support from the Welsh people as a whole and must receive from private donors and local authorities in the Principality adequate contributions for its maintenance." In considering how the additional sums required ought to be apportioned between the Imperial Exchequer and the locality (in this case the Principality) the medical school is designed to serve, the committee was guided by the extent to which local support, both over the whole of Wales and over Cardiff and its vicinity, already contributed towards university education as compared with the position in England. It also took into consideration the amount at present paid by the State in grants to medical schools in other parts of the country. Upon this the report contains the following observations:

3. With regard to the first of these points, we observe that, taking local support as including annual grants from local authorities, income from endowments and annual subscriptions, the ratio of local support to aid from the Exchequer in 1912-13 was 1.33 : 1 for the whole of England, while for the whole of Wales it was not more than 0.33 : 1. In making this comparison we do not wish to be understood as suggesting that the ratio of local support over an area which is in general of relatively low rateable value should be the same as it is in the case of England, of which the rateable value is relatively high, and we realize also that several heavy calls have of recent years been made upon the liberality of the Welsh people for the foundation of other national institutions connected with learning and preventive medicine. But even if these factors are taken as accounting in some degree for the low ratio of local contribution in Wales towards university education, we do suggest that, in a matter in which the interest of the whole country is so strong, and has been of such long standing, a larger measure of support may reasonably be expected.

When we come to consider the individual case of the University College of South Wales and Monmouthshire, which alone of the Welsh university colleges receives a grant for general maintenance from local authorities, the inadequacy of the local contribution stands out more clearly. Cardiff itself, and the districts which this college may be regarded as primarily serving, constitute a very thriving centre of commerce and industry, and their resources are fairly comparable to those of the wealthy English localities which contribute towards the maintenance of the modern English universities and university colleges. But whereas the ratio of local support to Exchequer grant averages, as we have seen, 1.33 : 1 for the English institutions, and in no comparable case sinks below 0.96 : 1; in the case of the college at Cardiff the ratio is only 0.45 : 1. We are convinced that the needs of university education in South Wales demand from Cardiff and the localities concerned a much larger contribution than is at present made if it is to be maintained at a reasonable level of efficiency.

4. The second of the considerations to which we referred above is the degree of assistance already given by the State to medical schools in England. The grants at present forthcoming in aid of these schools are paid by the Board of Education under the "Statement of Grants available in aid of Technological and Professional Work," and in the case of the largest school amounted in 1914-15 to nearly £4,600. This grant of £4,600 was in respect of nearly 300 full-time and about 80 part-time students. Under Regulation 7 of the "Statement" the maximum rates of grant which the Board can pay are £20 per full-time student and £8 per part-time student; but the rates actually paid in no case

reached these figures, and in the great majority fell very considerably below them.

It is in our opinion necessary to bear in mind these grants made by the Board of Education to the medical schools in England in considering what proportion the Exchequer can properly be asked to pay of the large additional sum required to establish in completeness at Cardiff a medical school which at the best will only be moderate in size. If Professor Hepburn's anticipations prove correct, the school will have fifty-three full-time students in the first year of the new conditions and 165 in the fifth year, when the total additional income required will have risen to nearly £10,000. At the same time we realize that due allowance should be made for the fact that the school is to be organized on the "unit system," the expenses of which may be expected to be greater than those entailed by the organization which at present prevails in the medical schools in England.

5. In paragraph 1 of this report we expressed our belief that for the maintenance of a national medical school at Cardiff additional sums will be required, rising from about £4,600 in the first year to about £10,000 in the fifth year. On a review of all the circumstances of the case we have come to the conclusion that half of the additional sums there specified as needed in each of the first five years might appropriately be contributed by the Exchequer on the understanding that an equivalent sum is forthcoming each year from fresh "local support" as defined in paragraph 3 above. Under this arrangement the Exchequer contribution would not in any of the five years exceed £5,000, and in most would fall considerably below that sum. It should be made a further condition of any grant from the Treasury that the share forthcoming from "local support" in each year should, with an equivalent contribution from the Treasury, make up the full amount estimated as necessary for the year.

It may be hoped that once the National Medical School is fairly started the success of its work will secure for it a stability and prestige which will assure its satisfactory development for the future. In view, however, of the fact that the task before the promoters of the scheme, involving as it does the building up on comparatively humble foundations of an important national institution, depends for its successful accomplishment on a variety of circumstances which cannot be foreseen with certainty, we consider that any such financial arrangement as we suggest should be subject to revision at the end of the first five years in the light of the experience which that period has afforded of the working and progress of the school. It is to be noticed that the estimates to which we have referred depend in part at least on the scale of fees proposed in Professor Hepburn's statement (see Appendix IV of interim report). In accepting these estimates we therefore assume that no alteration in this scale will be made during the period in question.

We are aware that if in accordance with our proposals a special grant is made from the Exchequer towards the maintenance of the school, there is a possibility of its overlapping to some extent with a portion of any increased grant to the University College of South Wales and Monmouthshire that might result from a reassessment of the grants to the Welsh university colleges, made on the recommendations of the Board's Advisory Committee on University Grants. This would, however, be a matter for adjustment by the Treasury and does not seem to call for further consideration by this committee, who are here only concerned with recommendations as to a "special grant" in aid of a national medical school for Wales.

The Treasury will not pay a special grant for the National Medical School for the year 1916-17, because the new physiological block is not yet completed and in use, and it is uncertain what the financial requirements of the school will be for this year. Any provision that may be necessary will be made in the estimates for 1917-18 on the receipt of information by January 1st next as to the financial position of the school and the grant likely to be required on the approved basis. The new grant will be conditional on the whole capital cost of the new buildings, including fittings, furniture, and equipment necessary for the complete school, being met entirely from local sources.

LIVERPOOL: INFANT AND MATERNAL WELFARE SCHEME.

A report by Dr. E. W. Hope, M.O.H., gives an account of the measures taken to preserve and protect infant life by antenatal, natal, and post-natal hygiene. The infant mortality-rate is nine times as great as it is among children between 2 and 5 years. One-half of these deaths occurs within three months of birth, and death to a great

extent depends on causes operating before birth. The mortality varies widely in different districts of Liverpool; for instance, twice as many children survived the first year period in the Walton as in the Scotland district. The work of the corporation infant welfare centres consisted originally in supplying a suitable food for infants whose mothers were unable to suckle them. They are also made use of for instructing mothers, and at the same time of ensuring the supervision of the feeding of these infants. Infantile cholera ranks as the most fatal disease of infants under 3 months of age, and it was found that deaths from this cause were fifteen times as numerous among artificially fed children as among breast-fed infants. Dr. Hope, while insisting on the importance of breast feeding, urges that every step should be taken to ensure this by antenatal treatment. Systematic home visitation by competent health visitors was inaugurated in 1897. The visitors put the mothers in touch with the Invalid Children's Association, or the various infant welfare centres where help and advice is obtainable, nursing mothers are cared for, and, where there is a lack of proper nourishment, means are taken to provide suitable food, so that the mother's maternal duties are not imperilled.

During the summer months particular attention is paid to the thickly populated districts of the city, and the home storage of food, the destruction of refuse and flies are matters to which householders are invited by cards and personal interviews to give especial care. Dr. Hope strikes a personal note in drawing attention to the qualifications of the health visitor. She should be brought into intimate contact with her surroundings, and display infinite tact towards the householders whom she desires to benefit. The midwives, who attend practically four-fifths of the total number of births, have themselves taken the initiative in advising those patients whom they know from past experience to require medical attention to seek medical aid at an early stage of pregnancy at the corporation antenatal centres. Two female inspectors specially trained to deal with ophthalmia neonatorum have been appointed, and as notification of this disease has been compulsory since April, 1914, no time is lost in bringing the infants under medical treatment. Nine beds and nine cots are reserved in St. Paul's Eye Hospital for these cases, and bacteriological examination is undertaken by the city bacteriologist in any case that is at all suspicious. How important prevention is in ophthalmia neonatorum may be gauged by the fact that over one-third of the inmates of schools for the blind have lost their eyesight from this cause.

In 1914 the mortality from puerperal fever was 1.34 per 1,000 births.

For girls attending the senior classes in the elementary schools a special course of instruction is provided on the "care of the baby," and practical demonstrations in the cutting out and making of a set of infant's first clothes are given.

The Liverpool Maternity Hospital and Ladies' Charity have provided a "rest house" available either for expectant mothers needing temporary rest and observation prior to the birth of the child or for a short period of post-natal tranquillity.

It will thus be seen that Liverpool is thoroughly cognizant of the importance of a healthy and vigorous race, and with a falling birth-rate is leaving no stone unturned to preserve the viability of the child, and thus in a measure stem the loss in population due to disease, and minimize the baneful influence of race suicide.

LONDON.

Infant Mortality.

At the meeting of the London County Council on May 16th, after a report on the subject from the Public Health Committee had been considered, a resolution was passed unanimously expressing regret that adequate steps had not been taken by all the local health authorities in the county effectively to diminish infant mortality and suffering by administering the scheme for maternity and child welfare outlined in the circular of the Local Government Board of July 29th, 1915, on this subject. An addendum by Mr. H. Mills was also agreed to, urging that action should be taken against the delinquent local authorities. It was resolved to communicate the opinion of the council to the Local Government Board.

Residential Treatment of Tuberculosis.

It was agreed to continue the existing agreements with various institutions for the residential treatment of tuberculosis for a further period of twelve months. It was decided also to continue the arrangement with the Metropolitan Asylums Board by which the council has the use of beds at three institutions under the control of that body; the number of adults undergoing residential treatment on January 1st was 112, and of children 236; by March 31st these numbers had been increased to 137 and 289 respectively.

Cases of Mental Defect.

During the first three months of the present year information was received of 105 alleged cases of mental defect in London, while the cases previously tabulated, but dealt with during the same period, numbered 116. Of this total of 221 cases 123 would be dealt with. The information was furnished in 78 of the cases by the local education authority.

Ireland.

We learn that certain adverse rumours concerning Dr. Maurice Hayes, Honorary Secretary of the Irish Medical War Committee, were in circulation in Belfast, and probably in other parts of Ireland, last week. Dr. Hayes was spending the Easter at Newcastle, co. Down, when the rebellion broke out in Dublin. He returned to Dublin with all speed, and was engaged in the Mater Misericordiae Hospital for the rest of the week, giving attendance to the wounded. He is not related to any other Dr. Hayes in Ireland.

THE REBELLION IN DUBLIN.

We have received the following note from a correspondent who was in Dublin during the insurrection:

The rebels took possession of the College of Surgeons on Easter Monday, and the building was held by them until the following Sunday, when they surrendered. The college overlooks Stephen's Green Park, which had also been occupied by the rebels; when they evacuated it, they fell back on the College of Surgeons. The windows, masonry, and massive columns in the front of the college show many signs of the heavy rifle fire of the military in their efforts to dislodge the rebels. The building, however, has suffered no irreparable or substantial damage. Previous to and at the time of the outbreak Trinity College was occupied by an Officers' Training Corps, and no attempt was made by the rebels to capture it. Practically no damage was done to the building, notwithstanding that the Officers' Training Corps was early engaged with small bands of the rebels behind the Bank of Ireland (old Parliament House).

In connexion with the charges and counter charges which have been made as regards firing on the Red Cross, I am inclined to believe, as the result of some personal investigation, that there is no foundation for them, and that in those cases in which a few Red Cross workers were injured this was accidental and the result of cross-firing between the military and the rebels. The wounds inflicted by the rebels were of a more varied character, and not so clean as those inflicted by the military. This is accounted for by the fact that many of the rebels were armed with old-fashioned game guns.

THE Local Government Board has issued an Order dated May 15th requiring medical officers of health in England and Wales to furnish to the Army Council particulars of all male persons between the ages of 18 and 45 on January 1st, 1916, who have been notified since February 1st, 1915, as suffering from tuberculosis. The object of the Order is to assist the Army Council in securing that men suffering from tuberculosis are not enlisted into the army. If the M.O.H. has difficulty in ascertaining whether a notified person was within the limits of age, he is instructed to include any doubtful case in the list supplied to the Army Council, which, it is suggested, should be prepared at the same time as the weekly statement of notifications required to be sent to the county medical officer of health. The information is to be regarded as confidential and is to be forwarded to the Secretary of the War Office in a sealed envelope.

Correspondence.

HOW MEDICAL WRITINGS MAY BE GIVEN A MARKED DEVELOPMENT.

SIR,—It is to be regretted that we have never adopted the admirable proposal of Dean Swift, to keep all adjectives under lock and key, and issue them to writers only on payment of a heavy fee. Certain words are so shockingly overworked by medical writers as to call loudly for the establishment of a Society for the Prevention of Cruelty to Adjectives. It would be invidious to quote from any individual writer to illustrate a vice so generally prevalent, and therefore I will disguise the reference by altering the disease; but, *mutatis mutandis*, I recently read in your columns an account that ran much as follows: A marked erythema was followed by a marked ulceration, with a markedly sinuous edge, which spread with marked rapidity, and developed a marked discharge, having a markedly purulent character, increased to a markedly large size, and was accompanied by a marked enlargement of the lymphatic glands. Treatment brought about a marked improvement with marked rapidity, and the ulcer healed, leaving a markedly thickened scar, which became the seat of marked keloid.

I do not suppose that medical writers are wantonly cruel to their adjectives, or that they are intentionally cruel to their readers; but, as Tennyson very truly says, evil is wrought by want of thought as well as by want of heart, and in these writings want of thought is so conspicuous as to arouse doubts of the intelligence of the writers. May I suggest to them that, while this unfortunate adjective and its corresponding adverb are so cruelly worked to death, there are plenty of others, much more vigorous, eating their heads off in the stable? In most cases in which "marked" is used it has no meaning, or what meaning it has is emotional, and not intellectual. It is used as a mere intensive, and has precisely the same significance as the adjective "bloody" in the mouth of a costermonger. I suggest that when medical writers desire to express some real quality in what they are describing they should choose the adjective which expresses that quality with accuracy. It is certain from the context that when the adjective "marked" is used to express a quality, the quality it is desired to express is not that of bearing a mark. It is used, as far as one can judge, as common form for decided, pronounced, evident, clear, unmistakable, unquestionable, perceptible, tangible, visible, slight, considerable, great, copious, abundant, actual, scanty, prevalent, scattered, occasional, and many more.

Another word that is abominably treated by medical writers is the word "develop." It is remarkable that, whereas patients used to catch, or contract, or exhibit, or manifest, or suffer from, or be attacked by, or have, or get diseases, they now do none of these things. According to medical writers, their patients now develop diseases—especially pneumonia. How they do this I do not know. "To develop" is not, except in photography, a transitive verb; and, although a disease may develop, it can no more be developed than it can be depended, or appeared, or looked. A disease, like many other things, may develop out of something else, or may simply develop. It may depend on something, or something may depend on it. It may appear, or a man may look on it. But a man can no more develop a disease than he can depend it, or appear it, or look it. No doubt he can assist a disease to develop, but this is not what medical writers mean when they say a man "develops" a disease—at least, I think not.

"He was given a pill." It is difficult to say which is more objectionable in this expression—the vile travesty of English or the falsehood. It is a falsehood to say he was given. He was not given. It is the pill that was given, and it was given to him. To put it in his own repulsive jargon, a writer who uses this expression is "developing a marked tendency to be given a kick." If I am again called upon to act as an examiner I shall take care that no candidate who expresses sloppy thought in such sloppy English "is given" (what on earth is the matter with the word "receives"?) a degree.

If a writer wishes to say that his patient was attacked by pneumonia, or received a dose of medicine, why cannot he say so in these words? There is nothing profane, or

obscene, or objectionable about them. If he wishes to say that a rash is copious, let him say that it is copious, and not that it is marked, which it is not. If he wishes to say that his patient is much worse, but finds this expression inadequate to express his emotion, let him not say the patient is markedly worse, which is intellectually silly, and emotionally inadequate: let him say the patient is a thundering sight worse.—I am, etc.,

Parkstone, Dorset, April 24th.

CHAS. A. MERCIER.

"THE SOLDIER'S HEART" AND ITS RELATION TO THYROIDISM.

SIR,—My article on the above subject in the *BRITISH MEDICAL JOURNAL* of April 15th having failed to draw a rejoinder from any of the protagonists with whom I was anxious to measure swords, I shall now bring the discussion to a close so far as I am concerned.

I must express my thanks to Dr. Harry Campbell for his very complimentary remarks. I fully appreciate his interesting observations on the causation of functional nervous disorders by morbid blood plasma, but I was dealing with what I considered to be a distinct entity, whether it be called morbid or functional, due to a definite cause, and I strictly confined my attention to the subject in hand. Moreover, the many toxæmias to which he refers can easily be eliminated in cases of "the soldier's heart."

I am afraid my friend Dr. William Inman has not read my paper carefully, or at least he has not profited thereby. It had nothing whatever to do with the toxic action of cordite, cocaine and veronal, the effects of tea on charwomen and washerwomen, scurvy and beri-beri. He says "tobacco is admittedly a common cause." A common cause of what? Personally I would much rather that soldiers had "tea taken from early morning to late at night" than unboiled water. The great success attending the work of another house-physician of mine, Lieutenant-Colonel Nimmo Walker, in the prevention of typhoid fever in the South African war was due to the fact that he always provided his men with boiled water on march and elsewhere.

The extraordinary confusion which prevails in medical literature is largely due to the fact that medical men will not adhere—probably from the lack of sufficient scientific training—to the dictum of Sir Isaac Newton, "that we should admit no more causes of natural phenomena than such as are both true and sufficient to explain their appearance." Can any one imagine Newton having a dozen causes to explain the fall of an apple?

I think I let Dr. Florence A. Stoney down very gently in my paper. There is no particular reason why I should do so now. I would strongly advise her before she begins to settle questions of priority to read a little more extensively and accurately. I can commend to her attention my letter in the *BRITISH MEDICAL JOURNAL* of November 20th, 1915, p. 747. The x-ray treatment of Graves's disease is now becoming a matter of ancient history, but she grumbles that her secondhand recommendation "got no support from the meeting" of the Royal Society of Medicine on January 18th, 1916. What I complain of is that Fellows of the Royal Society of Medicine, even Dr. Florence A. Stoney, can go about the world blind to the simplest fact until it hits them in the eye. They cannot see the wood for the trees. They are quite ready to give a dozen explanations of anything which they do not understand, like the ancient Fellows of the Royal Society who had a learned disquisition and many reasons why a fish does not displace water, until Charles II asked them to try, and, lo! the fact confuted their theories. The x-ray treatment of Graves's disease, or any other disease, should not be in the hands of amateurs. It is a powerful remedy; the dose not easily regulated, can readily work mischief, and, if prescribed by anybody and everybody, may soon fall into desuetude, like its employment in the treatment of spleno-medullary leukaemia, in which disease it was first used by Dr. William W. Keen, with, at first, an apparent amount of success. However, Dr. Florence Stoney seems to be an expert in x-ray work, and in her hands no ill effects may accrue, but, in the language of a Scotsman, I hae ma doots. She says "that toxic influences play a large part in causing thyroid degeneration," but what has that got to do with cases of hyperthyroidism? Her x-rays may cause

degeneration with a vengeance. It makes me smile to be told by a lady of whose existence I have only been aware since January 22nd, 1916, that my "paper is very valuable as again pressing this connexion." What connexion? I am afraid that accuracy of statement and clearness of definition are not strong points with Dr. Stoney. I suppose I should really have her testimonial framed, but Dr. Stoney must excuse me when I tell her that I am not going to indulge in such extravagance during war time.—I am, etc.,

Liverpool, May 13th.

JAMES BARR.

JEJUNOSTOMY AND JEJUNO-COLOSTOMY.

SIR,—Mr. Sampson Handley¹ and Mr. Victor Bonney² have raised the very important question of the best treatment of paralytic distension of the bowel from various causes. May I venture to congratulate both of them on their very interesting and suggestive papers, and also upon their success in saving lives under desperate conditions?

The issue is a little confused, for Mr. Handley deals exclusively with cases of general peritonitis with secondary obstruction, whereas Mr. Bonney's six cases include several instances of intestinal obstruction without peritonitis; but apparently these were such desperate cases that it would have been unwise to seek and remove the cause of obstruction in the form of band or kink. It may be remarked, however, that the finding and relieving of an obstruction of the small intestine is often a matter that can be accomplished in a very few minutes, and when this can be done it is clearly very desirable in order to avoid a secondary operation, either to close an artificial anus, or for the relief of recurrent obstruction. Except in extreme cases an effort should be made to ascertain the cause of the obstruction, even if it cannot be immediately removed, for when the obstruction is hopelessly irremovable an enterostomy should not be performed, for a permanent artificial anus in the small intestine is intolerable, and the higher it is the more intolerable, for most of the food and fluid are wasted, and the patient gets thin and also miserable from irritation of the skin. In these cases it is far better to make an anastomosis between the bowel above and below the obstruction, although this may involve a greater immediate risk.

1. But although it is clearly desirable to find and remove an obstructing band or kink, it is often necessary to drain the bowel in addition in order to save life.

2. Moreover, there are cases of intestinal obstruction so late and grave that an attempt to find the obstruction is dangerous.

3. In many cases of paralytic distension following peritonitis no very definite obstruction can be found. Moreover, in many of these cases a temporary enterostomy permanently relieves the obstruction.

In these cases, if an operation is to save life it must be speedy and simple. For this reason Mr. Handley's operation of jejuno-colostomy does not recommend itself to me so much as simple enterostomy. Moreover, a permanent fistula between the jejunum and colon is not likely to prove entirely harmless, judging by the history of patients suffering from jejuno-colic fistula following gastro-jejunos-tomy. These patients suffer from periodic attacks of diarrhoea and malnutrition. For less critical cases ileo-colostomy is especially valuable in the hands of an expert surgeon.

Mr. Handley has already mentioned many objections to jejunos-tomy as performed by Mr. Bonney,³ and I agree with him in not having been able to verify Mr. Bonney's three zones of intestine: "(a) A collapsed portion; (b) a portion above it much distended by gas, but containing no fluid matter; (c) a portion above that, distended with gas and fluid matter."

Mr. Bonney thinks it is necessary to drain the upper part of the jejunum. My experience is that it is neither necessary nor wise to drain the intestine so high up. It is not necessary for drainage at least 12 in. above the obstruction usually proves successful. It is not wise because every inch of small intestine is valuable for digestion and absorption. The ideal seems to be a simple, speedy, and efficient method of draining the distended bowel, and requiring no secondary severe operation to close the fistula. If this

¹ *BRITISH MEDICAL JOURNAL*, April 8th and 29th, 1916.

² *Ibid.*, April 22nd, 1916.

³ *Ibid.*, April 29th, 1916.

ideal could be approached surgeons would not be so averse to draining the small bowel in doubtful cases. For these reasons I strongly recommend the following simple plan, which I have used for years with a fair amount of success.⁴

The selected loop of bowel is drawn out, packed off, and clamped to prevent leakage. A soft rubber tube of quarter-inch internal diameter, and with several side holes close to the end, is inserted through a small opening on the free border of the bowel at least a foot above the obstruction. It is secured to the edges of the opening with a single suture of fine catgut. The tube is passed upwards and the invagination thus produced is confirmed by a few seromuscular sutures. Thus an airtight junction is made and the gas and liquid contents of the small intestine are freely drained away. As the contents of the small intestine are fluid a large tube is not required, and a small one has great advantages in damaging the bowel much less, so that spontaneous closing of the fistula is far more likely to occur in due course. The loop of bowel is returned into the abdomen amongst other coils, and not on any account is it to be retained outside the abdomen or sewn to the parietal peritoneum. The parietal wound is closed around the tube, and a stitch secures the latter to the skin to prevent any drag upon it. After the vomiting has entirely stopped for twenty-four hours the tube is released from the skin and gently withdrawn. By this time the fine catgut suture fixing the tube to the intestine offers little or no resistance. Peritoneal adhesions form very rapidly and prevent any leakage into the peritoneal cavity.

As a rule, the fistula soon closes spontaneously. Unless there is an obstruction lower down, it never can become an artificial anus, so that only a small proportion of the intestinal contents escapes through the fistula after the over-distension has been relieved. If the fistula fails to close and the patient is losing ground, the peritoneal cavity is opened between it and the middle line, and the attached loop is clamped and detached from the parietes. The edges of the fistula are freely pared and the opening thus left is closed, so that the suture line is transverse to the axis of the bowel, and no narrowing of the lumen results. Resection with end-to-end union is very rarely required.—I am, etc.,

London, W., May 9th.

R. P. ROWLANDS.

THE AMOUNT OF FREE HYPOCHLOROUS ACID IN EUSOL.

SIR,—Our attention has been directed to an error in calculation which has appeared in the papers on eusol published from this department.

The amount of free hypochlorous acid in the solution of eusol made up according to our recommendations was stated to be approximately 0.5 per cent. This should read approximately 0.27 per cent. As we have uniformly stated the weights of the constituents to be used in making the solution, this error does not in any way affect the validity of the results which have been recorded, but the point may have given rise to difficulty when solutions for intravenous injection were being tested by titration.

By following the directions given in our papers (namely, 12.5 grams bleaching powder, 12.5 grams boric acid to 1 litre of water) standard eusol is obtained, of which in general—

1 c.cm. = N/10 sodium arsenite solution
= 0.00354 gram chlorine
= 0.00262 gram hypochlorous acid.

Slight variations from this standard occur, depending on the percentage of "available chlorine" in the bleaching powder. With the best samples the percentage of hypochlorous acid in the solution rises to 0.3, but bleaching powder of B.P. standard (30 per cent. available chlorine) gives 0.27 per cent. hypochlorous acid.—We are, etc.,

May 15th, 1916.

THE CONTROL OF VENEREAL DISEASES.

SIR,—As I do not wish to seem to "rail in matters whereof I am ignorant," I will not enter into the discussion of the control of venereal diseases. My sole object is to

say a word in regard to the last paragraph of Dr. Helen Wilson's letter of April 28th. To Dr. Wilson, and to all those who entertain the hope that somehow and sometime "moral causes" may become efficacious in preventing venereal disease, I would earnestly recommend the perusal of Sanger's monumental *History of Prostitution*, published by Harper's in 1859, and those three grim chapters wherein Thucydides dwells upon things which, he says, "always have occurred and always will occur so long as the nature of man remains the same" (Bk. III, 82-84).

Sanger (p. 671) says, giving the report of a medical board in New York:

A Utopian view of the perfectibility of man might look for the remedy to this evil in universal early marriages, in domestic happiness, and in a universal moral sense which will compel men and women to keep their marriage vows. But, taking man as he is, we find the tides of society set with constantly increasing strength against early marriages; that domestic happiness is not synonymous with marriage, whether early or late; and that the moral sense which should teach all men to observe even their solemn promises would be miraculous. . . .

But is there no hope in the societies of moral reform? For the suppression or even the checking of the general vice, none whatever. The association in New York deserves much praise for its zealous benevolence. They have brought back some of these erring women to the paths of virtue, but they have done no more to stop the current of prostitution than he could do to dry up the current of the Hudson who dips water with a bucket.

—I am, etc.,

Cambridge, May 7th.

W. J. YOUNG.

ECONOMIC OBSTACLES TO EARLY MARRIAGE.

SIR,—Dr. S. G. Moore, in his Milroy lectures on infant mortality, has left untouched, I think, one aspect of the problem.

We now all agree that the State must give help to expectant and nursing mothers. We must also insist on the importance of encouraging youthful parentage. The present-day tendency to late marriages increases every year. The children of such marriages are either absent, few, weakly, or ailing. They lack the vitality, and are by no means of such value to the State as the children of marriages between 21 and 26 years.

The State wants, not weaklings, but healthy, virile, vigorous citizens. They can only come of early unions. Clearly the State must remove some of the economic obstacles to such unions.—I am, etc.,

Dublin, May 9th.

J. C. MCWALTER, M.D., R.A.M.C.

ELECTION OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

SIR,—Many reforms and changes are, we know, due directly to the war, but there is one change which is badly needed and which the war has made pressing. This change is in the manner of voting for the Council of the Royal College of Surgeons. At present the time is too great for the men of the United Kingdom but does not allow the men in Egypt or India, or those further off, to take any part in the election. At the present time a great many men are going to be disfranchised through serving their country as they are in France, Malta, Salonica, Egypt, and Mesopotamia, and even those within reach of letters, if Australians, will not have the voting papers sent to them as their address must be that in Australia. I should like to inquire if there is any really adequate reason for this time being chosen, and not, say, a period of two or three months to allow all to vote.—I am, etc.,

London, W., May 16th.

DUNCAN C. L. FITZWILLIAMS.

THE ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

SIR,—The British Medical Association has proved that it can elect all four of their nominees against all who may be nominated outside the Association. It is an abuse of power not to allow members of the profession resident in England not to have one representative on the Council who are non-members of the Association. The British Medical Association has less than 22,000 members, including those in the British Isles and in all parts of the world. The Association should act with some regard to justice and honour, and give the opportunity for at least one to be sent to the General Medical Council as direct representative of the profession in England who are

⁴ *The Operations of Surgery*, vol. ii, p. 335, fig. 183.

non-members of the Association. If the Association persists in always electing all the direct representatives for England, then contests will cease, which would be a matter for regret.—I am, etc.,

Blackpool, May 5th.

JNO. BROWN.

As it is open to any twelve registered practitioners resident in the constituency to nominate a candidate, it does not seem that there is much substance in Dr. Brown's grievance.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received since the last list was published are as follows:

£ s. d.	£ s. d.
Dr. E. D. H. Carpenter (twelfth donation, total £12) ... 1 0 0	Messrs. J. Hayllar and Son ... 1 13 1
Royal College of Physicians of Ireland: Mr. R. B. Balfour, D.L. ... 2 2 0	Mr. A. Chapman ... 0 6 2
Interest (Cister Bank) ... 0 14 1	Brighton and Hove Association of Pharmacy ... 4 7 6
Mr. J. H. Topliss ... 5 5 0	Mr. J. W. Bygott ... 0 5 0
	Mr. M. E. Morris ... 0 5 0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

The stock of clothes for the Belgian Doctors' and Pharmacists' Relief Fund has nearly been exhausted, and the Directress of the Committee of Clothing earnestly begs for further parcels of garments of all kinds. More especially the following articles are desired: Ladies' and children's summer dresses, stockings, and socks; suits for men; vests; sports coats for boys and girls; thin overcoats or raincoats. Parcels should be addressed Mrs. de Bless, St. Andrew's Parish Room, Palace Street, Westminster.

Universities and Colleges.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on May 11th, Dr. Frederick Taylor, the president, being in the chair.

Admission of Fellows.

The following members were admitted to the Fellowship, having been elected at the previous meeting:

Michael George Foster, M.D.Camb. (Harrogate), John MacLeod Hendrie MacLeod, M.D.Aberd. (London), Henry Lawrence McKinnel, M.D. Roy. Univ. Irel. (Belfast), Charles Hewitt Miller, M.D.Camb. (London), Harold Waterlow Wiltshire, M.D.Camb. (London), Charles Ernest Lakin, M.D.Lond. (London), Edward Alfred Cockayne, M.D.Oxf. (London).

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE secretary of the College of Surgeons has issued to the Fellows of the College the annual official circular on the elections. A meeting of the Fellows, he announces, will be held at the College in Lincoln's Inn Fields on Thursday, July 6th, at 3 p.m. for the election of four Fellows into the Council of the College in the vacancies occasioned by the retirement in rotation of Sir Alfred Pearce Gould, K.C.V.O., Mr. William F. Haslam, and Sir W. Arbuthnot Lane, Bt., and by the death of Mr. Stanley Boyd. Blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the secretary, and the same must be received by him, duly filled up, not later than Friday, June 9th. A voting paper will be sent by post to each Fellow, whose address in the United Kingdom is registered at the College, on Tuesday, June 20th. We are informed that there is much complaint about the very short time allowed for voting. Numerous Fellows are on the Continent, and their voting papers, even if they reach them, can hardly be returned in due time. The secretary particularly requests Fellows of the College to furnish him with their correct addresses.

The following list shows the present composition of the Council:

President.—Sir W. Watson Cheyne, Bt., K.C.M.G., C.B., F.R.S., C. (1) 1897 (substitute), (2) 1901, (3) 1909.
Vice-Presidents.—Sir Frederick H. Eve, C. (1) 1904 (substitute), (2) 1907 (substitute), (3) 1912; Mr. Harrison Cripps, C. (1) 1905 (substitute till 1908), (2) 1909.
Other Members of Council.—Sir A. Pearce Gould, K.C.V.O. (1) 1900, (2) 1908; Sir George H. Makins, K.C.M.G., C. (1) 1903, (2) 1911; Sir Anthony Bowlby, K.C.M.G., C. (1) 1904, (2) 1912; Mr. Charters J. Reynolds, C.B., C. (1) 1907, (2) 1915; Mr. W. F. Haslam, C. 1908; Sir W. Arbuthnot Lane, Bt., C. 1908; Mr. Bilton Pollard, C. 1910; Mr. C. A. Balam, M.V.O., C. (1) 1910 (substitute), (2) 1914; Sir John Bland-Sutton, C. 1910; Mr. D'Arcy Power, C. 1912; Sir Berkeley G. A. Moynihan, C. 1912 (substitute till 1919); Mr. James Ernest Lane, C. 1913; Mr. L. A. Dunn, C. 1913 (substitute till 1919); Mr. H. J. Waring, C. 1913; Mr. Stanley Boyd (deceased), C. 1914; Mr. W. Thorburn, C.B.,

C. 1914; Mr. W. McAdam Eccles, C. 1914; Mr. C. Ryall, C. (1) 1914 (substitute), (2) 1915; Mr. W. G. Spencer, C. 1915 (substitute till 1916); Mr. F. F. Burghard, C.B., 1915; Mr. H. F. Waterhouse, 1915.

CONJOINT BOARD IN ENGLAND.

At a meeting of Comitia of the Royal College of Physicians on April 27th, and of the Council of the Royal College of Surgeons on May 11th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following ninety-nine candidates:

* Hannah K. Alton, K. D. Atteridge, J. Aydon, A. J. Bado, H. J. Bensted, D. S. Brachman, J. P. Bracken, J. R. R. Brogden, A. S. Carter, H. H. Castle, L. A. Célestine, G. E. Chissell, *Hester M. Church, *Mabel C. Clark, A. H. Clarke, P. S. Clarke, H. M. Cohen, W. H. Coldwell, W. M. Crombie, R. C. Davenport, S. G. Dunn, F. Dunphy, M. Dwyer, W. F. Eberli, A. W. F. Edmonds, P. O. Ellison, G. I. Evans, H. S. Evans, L. W. Evans, W. Farquharson, G. Fehrsen, E. A. Fiddian, S. W. Fisk, M. R. V. Ford, A. R. Fuller, D. H. A. Galbraith, G. T. Garraway, S. C. Ghose, C. C. Goo'ell, P. H. S. Greenish, *Ethne Haigh, J. C. N. Harris, S. F. Harris, A. N. Haworth, N. N. Hayson, W. A. Hotson, E. G. Howell, G. P. B. Huddy, Edith C. Hudgell, S. Hutchinson, T. H. Jackson, B. B. Jareja, W. G. Johnston, A. M. Jones, T. Jones, V. Kameneff, T. L. Kan, R. P. Langford-Jones, E. E. Lightwood, C. W. B. Littlejohn, H. B. Logan, P. G. McEvedy, S. S. Malkani, P. S. Marshall, F. C. Mason, Adeline M. Matland, B. H. Mellon, H. W. L. Molesworth, T. D. Morgan, A. G. Morris, G. Moulson, S. Mutiah, K. V. Muttukumaru, F. Newey, D. C. Norris, A. J. Orenstein, F. C. Ormerod, P. E. D. Pank, G. E. Paul, R. B. Powell, J. N. Puri, H. M. Quackenbos, R. Rau Damodar, C. R. Reckitt, B. T. Rose, P. G. Russell, M. Schwartz, D. M. Smith, W. Steadman, H. G. Stormer, G. C. Swanson, D. G. C. Tasker, H. W. Taylor, G. B. Wild, B. W. Willenberg, G. C. Williams, A. Williams-Walker, C. E. Wise, R. S. Woods.

* Under the Medical Act, 876.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

THE Dr. Edith Pechey Phipson Post-Graduate Scholarship of the value of £40, awarded annually in June by the Council of the London (Royal Free Hospital) School of Medicine for Women, is open to all medical women, preferably coming from India, or going to work in India, for assistance in post-graduate study; it may be held for three years. Applications on a form which will be supplied must be received by the secretary of the school by May 31st.

The Services.

R.A.M.C. (TERRITORIAL).

(Gratuity.)

WE are officially informed that officers of the Royal Army Medical Corps (Territorial Force) who resign their commissions owing to unwillingness to undertake the Imperial and general service obligation are entitled to the gratuity.

EXCHANGES.

M.O. to Divisional Train, Army Service Corps, probably at home for some time, desires immediate exchange with M.O. in 50th Division abroad.—Apply No. 1950, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

M.O. Wessex Division, at present under canvas at Hursley Park, Winchester, would like to exchange with Territorial M.O. serving under the A.D.M.S., Portsmouth. Address No. 1949, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medico-Legal.

ILLEGAL OPERATIONS.

IN the High Court of Justiciary, Edinburgh, on May 4th, Dr. John Thomas Dickie, 37, Lauriston Place, Edinburgh, and Ann Taylor, 4a, Lauriston Gardens, Edinburgh, were charged with having performed illegal operations upon two women, in the one case between June 6th and 13th, 1914, and in the other between January 29th and February 5th, 1916; both the women died. The jury found the prisoners guilty, and the Lord Justice Clerk, in passing sentence of five years' penal servitude on each prisoner, said that it was impossible to regard the offence of which they had been found guilty otherwise than as serious.

Obituary.

ARNOLD WILLIAM WARRINGTON LEA,
M.D.LOND., F.R.C.S.,
MANCHESTER.

ALTHOUGH Dr. Arnold Lea had been in ill health since the autumn of 1914, when he was compelled to retire from practice, the news of his death on May 7th at Southport was received with deep regret by his former colleagues in Manchester.

Dr. Lea, who was in his 49th year, was a son of Mr. Edward Lea of Sandbach, Cheshire, and his maternal uncle was Dr. Warrington of Congleton. He was a student of Owens College, Manchester, and obtained the diploma of M.R.C.S.Eng. in 1889, and that of F.R.C.S. in 1892. He graduated M.B.Lond. in 1890, taking honours in obstetric medicine and forensic medicine, and the gold medal and university scholarship in the former subject. He proceeded to the degree of M.D.Lond. in 1892, and graduated B.Sc.Vict. in 1904.

After holding resident appointments at Queen Charlotte's Hospital, the Manchester Royal Infirmary, and elsewhere, he settled in 1895 in Manchester, and became assistant to the late Sir William Japp Sinclair. In 1897 he joined the staff of the Northern Hospital for Women and Children, Manchester, where he distinguished himself as a sound and enterprising surgeon. In 1905 the Northern amalgamated with St. Mary's Hospital for Women and Children, and Dr. Lea remained on the staff. He took an active part, together with Sir W. Sinclair and Dr. Fothergill, in the foundation of the *Journal of Obstetrics and Gynaecology of the British Empire*. In 1912 he was elected president of the North of England Obstetrical Society. He contributed several papers of high merit to the Obstetrical Society of London, of which he was a Fellow, and to the Northern Obstetrical Society, and wrote an important work on *Puerperal Infection*.

Apart from the eminent position which Dr. Lea had attained as a gynaecologist with a large consulting practice, he had shown from the beginning of his career considerable literary powers. During and for some time after his student days in Manchester he was one of the most attractive speakers at the Manchester Medical Students' Debating Society, taking interest in general, scientific, literary, and especially sociological subjects. He became a member of the Manchester Fortnightly Society, where he frequently took part in discussions, and read several papers showing a highly cultivated literary taste, and eventually he was elected president of the society. Those who knew Dr. Lea intimately realized his sterling qualities as a man as well as his brilliance as a gynaecologist. He was always a delightful companion and faithful friend. About three years ago, largely as a result of overwork, he had a serious nervous breakdown, and was compelled to give up all work for some months. On returning to his duties he hoped to be able to work with his previous energy, but soon found himself compelled to retire permanently, and his death hardly came as a surprise to his numerous friends.

A funeral service for Dr. Arnold Lea was held at St. Chrysostom's Church, Victoria Park, Manchester, on the morning of May 11th, at which Professor Donald, Professor Elliot Smith, Dr. W. E. Fothergill, Colonel J. W. Smith, Dr. Lloyd Roberts, Dr. Fletcher Shaw, and Dr. W. K. Walls attended as representatives of Victoria University. The interment took place at St. Peter's Church, Congleton, in the afternoon.

Dr. C. RONEY SCHOFFIELD, of Southport, sends us the following tribute to Dr. Lea's memory:

The evening before his death he had greeted me with his old pleasant smile, though too exhausted to speak or take much interest in what went on around him. Over twenty years of intimate friendship, ending with over a year's close medical attendance on him, has been for me a privilege which I shall recall and value always, for during that time I learnt many lessons that only the example of a life of singular purity in thought, word, and deed can effectually teach.

Arnold Lea possessed a brilliant intellect, but, above all, he had the power of concentration and the gift of memory. His reasoning and deductive powers were logical and sound, while his conclusions invariably gave the impres-

sion of being the result of painstaking thought and conscientious research. No mere local fame belonged to him. Lea took a very high place among the English gynaecologists, but I want to speak of the man—the friend I loved. Never have I heard an uncharitable opinion, an unkind word, a harsh criticism pass from his lips on any man he knew. In any discussion that might arise Lea invariably found the way to introduce some excuse for the condemned action, some reason for an apparently malicious act, some virtue which palliated the alleged vice. And these without vehemence and without aggressiveness, but with a smiling gentleness which carried with it a reproof to a possible slanderer and aroused sympathy in the unprejudiced listener. He was ever ready to admire other men's good points, always generous in his estimate of them, and unstinting in his praise. His own achievements and his own methods were rarely referred to, and when he did allude to the latter his tone was almost apologetic, but lacked no enthusiasm when he described some colleague's work in the same direction. This characteristic modesty, together with his infinite charity, was, I think, what so endeared him to his friends. His ready sympathy in trouble, his effectual and shyly given help, his utterly unsuspicious nature—always attributing the best motives to any one's actions—these were the characteristics which make him so bitterly mourned and render his memory undying.

Had he lived a little longer, rewards for his long untiring devotion to his work must have fallen thickly upon him, for he fell ill when the years of toil were fructifying. His short married life, however, was one of intense happiness, as it afforded him through the whole length of his long and tedious illness the alleviation which only the most unselfish, devoted, and skilled wife could have given. While his place among his friends can never be filled, while an undying sorrow has come to his nearest and dearest, they can take some measure of comfort in knowing that what reward may be due to a man who has, by his example, left the world better than he found it, that reward is due to Arnold William Warrington Lea.

Dr. BRIGGS, Professor of Obstetrics and Gynaecology to the University of Liverpool, sends us the following appreciation:

Amongst the many prominent public services of the late Sir William Sinclair, none could have been more impressive than his choice of Dr. Arnold W. W. Lea as lecturer in obstetrics in the Victoria University (then Owens College), Manchester. Dr. Arnold Lea was physically a robust and powerful man with a bright and genial disposition. His extraordinary abilities were reflected in the highest of professional records. The addition then made to our ranks in the North of England has remained one of our happiest possessions. Until Dr. Lea's enormous energy had been too deeply drained by impaired health, there followed one continuous succession of written contributions and loyal services to the branch of the profession he so early adorned.

His book on *Puerperal Infection*, published in 1910, planned beyond the range of a textbook, became the standard work of reference. Evidence of the depth, extent, and difficulties of this work is borne in its pages. Its merit as a personal and professional sacrifice on the author's part is conspicuous in conjunction with the strenuous professional efforts of a junior teacher in an important and growing medical school. Of Dr. Arnold Lea's intense loyalty to Manchester, to its university, to his chief and to his colleagues there was one long, continuous, and convincing manifestation. Manchester in her great strength realizes the gigantic loss of one who had so capably, worthily, and cheerfully shared in the toils of her professional ranks. Dr. Arnold Lea originally came amongst us with the bright and welcome promise of a most brilliant future; he was soon marked as one of our leaders. Our sorrowful hearts mourn his departure, for he was a loving and loved friend to all of us.

C. J. GIBB, M.D.,

CONSULTING SURGEON, THE ROYAL INFIRMARY, NEWCASTLE.

Dr. CHARLES JOHN GIBB died in Newcastle-on-Tyne on May 13th, in his 90th year, being the oldest doctor in the Northumbrian capital, where his father, Dr. John Gibb, had practised for forty years. After serving an apprentice-

ship he attended some London and Continental schools, and took the diploma of M.R.C.S. and L.S.A. in 1847. Returning to Newcastle, he became connected with its Royal Infirmary, first as house-surgeon. He was afterwards surgeon to the institution; and remained to his death a member of the consulting staff. In 1853, when a grave epidemic of cholera occurred in Newcastle and more than 1,500 deaths were registered, Dr. C. Gibb took an active part in stamping out the disease, and drew up a report on epidemic cholera, which was published in the same year in the *Medical Times and Gazette*. The degree of M.D. of Durham was conferred on him in 1859. He was attached to the Newcastle-on-Tyne College of Medicine for a time as lecturer on pathology, physiology, and anatomy, and examiner in pathology.

JAMES WILLIAM WHITE,

LATE PROFESSOR OF SURGERY, PHILADELPHIA.

PROFESSOR JAMES WILLIAM WHITE, of Philadelphia, died on April 24th. He had been ill for some months, but the immediate cause of death was pneumonia. He was born in 1850. He was the son of Dr. J. W. White, founder of the Maternity Hospital of Philadelphia, and took the degrees of M.D. and Ph.D. at the University of Pennsylvania in 1871. Soon after graduation he went as a member of the scientific staff of the Hassler expedition under Agassiz. The expedition sailed from Boston on December 4th, 1871, visited the West Indies, the Straits of Magellan, Patagonia, and Tierra del Fuego, both coasts of South America, the Island of Juan Fernandez, the Galapagos Archipelago, Panama, and Mexico, and reached San Francisco on August 31st, 1872. On his return to Philadelphia White was for some years resident surgeon in the Eastern Penitentiary. Then he became associated with Dr. Hayes Agnew, and began a career of forty years as a teacher in his Alma Mater. He was first assistant, then professor of genito-urinary surgery. After some years he became professor of clinical surgery, and later, John Rhea Barton professor of surgery. In 1911 he was appointed a trustee of the University and Emeritus professor of surgery. He was senior surgeon to the University Hospital, and consulting surgeon to the Philadelphia, Jewish, Bryn Mawr, and Maternity Hospitals.

Professor White contributed largely to medical literature. He was joint translator and editor with Simes of Cornill's treatise on syphilis (1875); joint author with W. W. Keen of the *American Textbook of Surgery* (1896) and with Martin of a work on genito-urinary surgery (1897). He was one of the editors of the *Annals of Surgery*, and author of numerous papers on the surgery of the spine, the supposed curative effects of operations *per se*, the topical treatment of focal epilepsy, the Roentgen rays in surgery and other subjects. He also wrote a memoir of Hayes Agnew. On the outbreak of the war he came forward as an ardent supporter of the Allies, and in many letters and pamphlets—*A Primer for Americans*, *A Textbook for Americans*, and *Germany and Democracy*—he vigorously denounced Teutonic aggressiveness. His enthusiasm led him to establish a branch of the American Ambulance in Paris and to take personal charge of it for three months in 1915. His health, which was already undermined, broke down under the strain of the work.

Dr. White in his younger days was a famous swimmer and a good all-round athlete. His belief in the value of athletics led him in 1884 to become professor of physical education in the University of Pennsylvania; that post he held without salary for several years. In 1888 he appeared as a principal in the last duel fought in Philadelphia: it was on a quarrel with a Congressman as to the kind of uniform that should be worn by a surgeon of the City Troop in which he held a commission.

Dr. White was for many years in the habit of taking three months' holiday, and how he began this he explained once to the writer of this note. After ten or twelve years' constant work without a holiday as demonstrator of anatomy and as a teacher of surgery, he was beginning to attain considerable success in practice when his health gave way and his physician insisted upon his taking a long holiday. He obeyed, but in the lowest spirits, feeling that all the results of his strenuous work were to be thrown away. He stayed away the prescribed three months, and returned to find not that the public had

forgotten him, but that it was disposed to assume that he would be all the better for his holiday and for the new views in surgery which he would have picked up in Europe. In the succeeding nine months he made twice as much money as he had made in any preceding year, and he drew the wise conclusion that if that was what the public wanted it was for him to humour it. For many years he was an annual visitor to this country, where he made many friends, but latterly had gone to other parts of the world, and in particular made an adventurous journey to Alaska a few years ago.

Dr. White had many distinguished friends in his own country; among them were Henry James, Edwin A. Abbey the historical painter, and John Singer Sargent, who painted his portrait for the University of Pennsylvania after White had received the degree of LL.D. from the University of Aberdeen on the occasion of its quatercentenary in 1906. He was very popular with all sorts and conditions of men, and an idol of students, in whose welfare he always showed the liveliest interest.

DR. F. C. PLUMPTRE HOWES died at his residence in Lincoln on April 25th, aged 75. He studied at King's College, London, and at Edinburgh, and graduated M.D. Edin. in 1864. He was for many years house-surgeon to the Lincoln General Dispensary, where he proved a great friend of the poor, who regretted his retirement in 1896 to engage in private practice. Dr. Howes was a very familiar and popular figure in Lincoln.

DR. JAMES RICHARD LOWNDS died at his residence in Newcastle-on-Tyne on April 28th at the age of 82. He was a native of that town, and studied medicine there, and took the diplomas of M.R.C.S. and L.S.A. in 1855. Dr. Lownds practised first at Walker, near Newcastle, where he was for a time medical officer of health and consulting surgeon to the local hospital. Later in life he established a large practice in Newcastle, and was highly esteemed by his patients. He retired some two years ago, after having been in practice for nearly sixty years. His two sons are both doctors. Dr. Lownds was buried at Jesmond Old Cemetery on May 1st.

DR. TIMOTHY MURPHY of Birmingham died at his residence in Small Heath on April 23, aged 43. Born in 1872, he studied at Queen's College, Cork—his native city—and at Edinburgh and Glasgow, taking the diplomas of L.R.C.P. and L.R.C.S. Edin. and L.F.P.S. Glasg. in 1894. He practised for a time in the Tonymandy area, Wales, and on leaving was presented with a gold watch and guard as an acknowledgement of his valued services. Dr. Murphy set up in practice in Birmingham seventeen years ago, and became a member of the Central Division of the Birmingham Branch of the Association, and for a time member of the Birmingham board of guardians. The poor, together with Dr. Murphy's professional brethren and relatives, attended the requiem mass at St. Michael's, Moor Street, in great numbers. Dr. Murphy leaves a wife and five young children.

DR. ROBERT WALLACE BRUCE SMITH, of Toronto, died on March 28th, after an illness of some months. He was born at Mitchell, Ontario, in 1857, and educated at the Newmarket and Newburg High Schools. He took his medical degree at Victoria University, Toronto, in 1879, and went into practice at Seaford, Ontario. In 1894 Dr. Bruce Smith was appointed to the staff of the Hamilton Hospital for the Insane, and became superintendent of the Orchard Convalescent House attached to that institution. In 1900 he became assistant medical superintendent of the Brookville Asylum, and four years later was appointed inspector of asylums, hospitals, and charities for the province of Ontario. Dr. Bruce Smith was well known throughout Canada as a specialist in neurology and psychiatry, and a frequent contributor to medical literature. His genial nature made him many friends, and his personal qualities commanded both respect and admiration. In 1908 he made an official tour of the large hospitals of the United Kingdom as a representative of the Ontario Government. In 1894 he was appointed Vice-President of the Canadian Medical Association; in 1905 Vice-President of the Charities and Correction Association; and in 1909 a director of the Canadian Purity Association.

Medical News.

THE Library of the British Medical Association has now received, through the courtesy of Dr. Thurstan Holland of Liverpool, Part I of Section XXII (Radiology) of the International Medical Congress, 1913. The series of the proceedings of that Congress in the Library is thus completed.

IN view of the great increase in the prevalence of venereal disease in Italy caused by the conditions of warfare the Minister of the Interior has issued a circular to all prefects throughout the kingdom calling attention to the necessity of taking active measures against the scourge.

A CHAIR of clinical preventive medicine and hygiene has been established in the University of California, the object being to bring about the most effective possible co-operation between the University and the California State Board of Health. Dr. Wilbur A. Sawyer, secretary and executive officer of the Board, has been appointed to the new chair.

IN the night of Saturday-Sunday next, May 20th-21st, at 2 a.m., the time of all railways, and at post offices and other Government establishments, will be put forward one hour to 3 a.m. This altered time will be used for all ordinary purposes during this summer, and will apply to hours of medical practice, panel or other. It is believed that the alteration will reduce the number of hours during which artificial lighting is used in the evenings.

THE Ingleby lecture before the University of Birmingham will be given this year on Wednesday next at 4.30 p.m. in the medical lecture theatre. The lecturer is Dr. T. Sydney Short, physician to the General Hospital, and the subject chosen is gastric ulcer and its complications.

THE circumstances of the death of the wife of Dr. A. C. Herbert, of Sheerness, were recently the subject of an inquiry by the coroner for Kent. A post-mortem examination, confirmed by bacteriological examination, established the fact that death was due to cerebro-spinal fever, and the jury appended to a verdict to that effect the following rider: "The jury desire to express their deepest sympathy with Dr. Herbert in his loss, and feel grieved he should have been put through this painful ordeal as a result of dissatisfaction of relatives, and further sincerely hope that the doctor's career will be in no way affected by this painful inquiry."

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attilology, Westrand, London*; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

"INDICAN" invites suggestions for treatment of long-continued toxæmia, due either to intestinal intoxication or deep-seated ischio-rectal abscesses, thrice operated on. Symptoms: Severe urticaria, subacute diffuse fibrositis, indican, consistent subnormal temperature 95° to 97°. For the last three months there have been symptoms of mucous colitis, with six to eight motions daily, which have not yielded to diet or drugs.

INCOME TAX.

H. S. took over an additional practice on January 1st, 1916. He has paid one-quarter of the tax assessed on that practice for the financial year 1915-16, and expects to be called upon to pay tax thereon for 1916-17, although the earnings of the corresponding portion of his present practice are now appearing in his own books and will come in for future assessment. Can his wife's income be reckoned separately for purposes of "abatement"?

* * It was decided in the case of *Bell v. the National Provincial Bank* that the purchase and incorporation of a

branch into a business constituted a "succession," and rendered the successor liable to account for tax on the average profits earned thereby. It may be presumed that the Revenue officials were relying on that decision in requiring payment of the tax for the quarter to April, 1916. It should be remembered that our correspondent's return for 1915-16 would be based on the average profits for the three years 1912, 1913, and 1914, and it would seem to be not inequitable that on taking over an additional practice he should pay more tax than he would otherwise have done. This remark also applies to 1916-17, seeing that the profits of his new "branch" prior to January 1st, 1916, did not affect our correspondent's books, and therefore do not enter into a computation of his own profits on the average of the three years, 1913, 1914, and 1915. It might be well for H. S. to see the surveyor of taxes and come to an agreement with him as to the probable amount of the profits for 1913, 1914, and 1915 of the practice which is now amalgamated with his own, in order that he may be able to make a return for 1916-17 on the full average.

The wife's income is still reckoned with the husband's for purposes of abatement, except as regards income separately earned by her own personal labour, and then only where the amount of the total joint incomes does not exceed £500 per annum. This still holds good notwithstanding the right of separate assessment under Section 9 of the Finance Act, 1914.

ANSWERS.

PRURITUS OF FACE.

DR. WILLIAM BRAMWELL (Liverpool) writes: In reply to "Country Doctor," if his patient has been long under treatment, he may have noticed that the attacks increase in severity at this time of the year. If so, they are probably due to the ingestion of spring rhubarb. The number of cases suffering from "subcuticular roughness" and those conditions which Dr. Sequeira looks upon as allied to "Hutchinson's summer prurigo" is greatly increased when spring rhubarb is a daily article of dietary, the oxalic acid in the rhubarb being probably responsible for a lowered specific gravity of urine and the consequent retention of toxins; such lowered specific gravity being almost invariably present in such cases and due to a lowered vitality of the kidney eliminative cells, possibly a specific effect of the oxalic acid when there is an insufficiency of lime salts for its combination and elimination as calcium oxalate. The oxalic acid, therefore, or its combinations cause the mischief by its own retention and that of the products of katabolism. Hence a vicious circle is set up which may continue long after rhubarb has gone out of season. Nor will such vicious circle be broken and the numerous ailments it may give rise to in the more susceptible cases be cured until many other articles of diet besides rhubarb which have an irritative or toxic effect on the tissues be entirely expurgated from the dietary. In skin affections from such causes, x rays, like sun rays, very naturally do harm, as in "Country Doctor's" patient, and local applications are of very little use. In the BRITISH MEDICAL JOURNAL, 1902, I published a case of urticaria acuta in a child, brought on through an excessive ingestion of spring rhubarb, a writer in a previous issue having recorded a similar experience.

LETTERS, NOTES, ETC.

EMULSIONS FOR WIDAL'S TEST.

DR. ARTHUR HARDEN, Deputy Director, The Lister Institute of Preventive Medicine, Chelsea, Gardens, S.W., writes: Dr. Alfred C. Coles, in his paper on "An easy and rapid method of doing Widal's reaction for typhoid" (p. 684), states that "emulsions of dead typhoid bacilli" (for use in the Widal test) can be obtained from the Lister Institute. This statement needs correction. We understand that the standards department of the Pathological School at Oxford is prepared to issue killed standard emulsions of bacteria of the typhoid group to persons requiring them for agglutination work, and it therefore has not been necessary for the Lister Institute to supply such emulsions.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	40 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea restant* letters addressed either in initials or numbers.

THE LOUSE PROBLEM AT THE WESTERN FRONT.

BY

LANCE-SERGEANT A. D. PEACOCK, M.Sc. (DUNELM.),
R.A.M.C. (T.F.);

FORMERLY ENTOMOLOGIST TO THE GOVERNMENT OF SOUTHERN
NIGERIA; LECTURER IN ZOOLOGY, UNIVERSITY
OF DURHAM.

The insect dealt with in this paper is the clothes or body louse—*Pediculus humanus*, Linnaeus; order *Anoplura* or *Siphunculata*.

ENTOMOLOGICAL. MORPHOLOGY.

Technique.—Microscopical preparations were made as follows:—the insects were chloroformed, fixed in formalin (10 per cent.) for a day, brought through the alcohols (50 per cent., 70 per cent., 90 per cent., absolute), cleared in xylol for a day or two, and mounted in Canada balsam. The drawings have been carefully prepared, and are as detailed and accurate as opportunity has permitted, but further work will, no doubt, reveal other features which may necessitate slight additions and modifications. The musculature and mouth parts, for instance, are not fully worked out.

The nomenclature of the parts may possibly need correction. As I am not aware of any other detailed drawings of this insect, it is hoped that these will be of utility.*

EXTERNAL CHARACTERS.

Only the most significant features are dealt with. The female is the larger, being about 4 mm. in length, while the male is about 3 mm. The proportion of the sexes is about equal. Soldiers speak of *black* and *grey* lice. With regard to the question whether these are different species, no distinctive features have been discovered which would necessitate separate classification. The black louse has a more dusky integument, the edges of the body are darkly pigmented and the dorsal regions of the segments darkly patched. Murray gives the information that the different coloured races of men have lice coloured to match. On the question whether the black variety exists peculiarly at the front, or more abundantly in proportion than in England, there is no evidence available. Eighteen hundred lice counted yielded 5.4 per cent. black. The bristles, of which there are two kinds, long and short, are placed all over the body, are somewhat sparse in number, and are roughly symmetrically arranged.

Head (see Figs. 3, 4, 5, and 6).

This bears the very simple sensory organs—the antennae and the black eyes. The entrance to the alimentary canal is at the anterior of the tubular chitinous mouth-part (5), which is nearly surrounded by a projecting sheath (1). This sheath rises from a thin chitinous diaphragm, which forms the greater portion of the anterior of the head. The dorsal margin overlaps and forms a blunt rostrum (2). Ventrally, are a pair of chitinous structures of unknown significance (3).

Thorax.

The three thoracic segments are fused and their boundaries are not sharply marked off. Mid-dorsally is an invagination. There are three pairs of strong legs which each end in sharp powerful gnarrels and spines.

Abdomen.

There are eight segments, the two posterior being fused. Each of the first six bears a breathing hole, the stigma, on either side. The male is pointed at the posterior, and the sharp tip of the penis may often be seen extruded. The female's posterior is bilobed and ventrally shows a pair of tooth-like appendages, the gonopods, which assist in copulation. In both sexes the anal region is fringed with numerous bristles.

* For bench room and facilities to finish certain microscopical and recording work I wish to acknowledge the kindness of Captain McNea, R.A.M.C.

INTERNAL CHARACTERS.

Mouth-parts.

The interesting question of the homologies of the mouth-parts the writer desires to leave till a more appropriate season, and, in the absence of knowledge on this point it would be best to use non-technical terms. The chitinous mouth-parts are (1) an outer structure adapted for sucking and for supporting the first pharynx; (2) two inner structures adapted for stabbing.

The strong outer apparatus is tubular for a certain length at the mouth end. When the insect is not feeding the entrance is lined with sharp chitinous teeth, seated in tissue and pointing inwards. When feeding the outer structure is thrust forward a little so that the mouth region projects beyond the protective sheath. This action, in some way, appears to relax the tissue bearing the teeth, and these, instead of lining the mouth, come to fringe it and point outwards. The first half of the outer structure, dorsally, is an arch which forms the roof of the beginning of the gullet. Backwards from the arch run two limbs to which are attached the protractor muscles which out-thrust the structure. They also support the sides of the first pharynx. In the arch run two curved walls, which appear to have their origin just ventral to where the arch bifurcates, and in the floor of the pharynx. Within these two curved walls lie the anterior portions of the two stabbing organs.

The inner mouth-parts, the two stabbing organs, are lodged in a tubular sac lying below the oesophagus and extending from the back of the head to the first pharynx. They are similar in so far as both are flexible, long (nearly the length of the head), enter the first pharynx together, and bifurcate posteriorly. They vary in detail. The uppermost resembles a thin, broad chisel, double-grooved along part (?) of its length. The lower is like a gouge bit, the tip being three-pointed. Protractor and retractor muscles bring the apparatus in and out of action.

Alimentary Canal.

The writer does not fully understand the relationships of the various structures composing the canal anterior to the first pharynx. It would seem, however, when human blood is being sucked, that a gutter or tube is formed, having for sides the curved structures of the outer mouth parts and for a floor the posterior length of the broad stabbing organ. It is possible, too, that the under-stabbing organ becomes closely apposed to the upper, so forming a narrow tube leading to the wound.

Following the feeding tube is the first pharynx, which has muscular walls and is lined with chitin. Its function as a pump is secured by the action of five pairs of muscles, which diverge from it dorsally. The second and smaller pharynx resembles the first. It leads to a narrow gullet which opens into the stomach.

For information concerning the salivary glands the writer is indebted to Major Sydney Rowland, R.A.M.C. The glands are situated far back in the thorax and consist of two on each side, one bifurcated and one globular. The duct from the bifurcated gland joins with that of the accessory gland to form a single duct, and this opens into the sac of the stabbing organs.

The stomach is of very large capacity and, anteriorly, has two pockets. A short, narrow, single-looped intestine follows and leads to a slight swelling, the beginning of the rectum. Into the intestine open eight excretory Malpighian tubules. A short rectum ends at the anus.

Circulatory System.

This is probably typical, a long tubular heart lying in a pericardial space dorsal to the gut, with few vessels and large blood sinuses.

Respiratory System.

The lateral stigmata lead to the tracheae which branch to smaller vessels to ramify the tissues.

Nervous System.

The brain lies behind the second pharynx, above the gullet, and is connected by lateral commissures to a sub-oesophageal portion. Backward from the sub-oesophageal ganglia runs the ventral nerve cord. An optic nerve runs

from the brain to the eye. The antennae are sensory. Apart from these, there is a marked absence of any structures denoting special sense.

Reproductive System.

With the exception of the penis the reproductive organs of the male have not been noted. Of the female only the eight (?) ovaries have been noticed. They are long tubes containing ova at various stages of development.

INSECTS, ETC., RESEMBLING LICE.

Many insects, etc., found in dug-outs, at first and casual glance may be easily mistaken for lice. The woodlouse or slater, a crustacean related to the crabs and lobsters, is regarded as an ancestral or originaive type of louse. Springtails, primitive insects which move by leaping, resemble lice when at rest. Certain small beetles may be taken for adult lice, and small mites, relatives of the spiders, look like young lice. These mites are very common in food which has been trodden into empty sandbags and the floors of dug outs.

HABITS OF LICE.

Habitat.

For shelter the louse depends upon the clothing, particularly the garments worn next the body, and prefers the comfort of the seams. Soldiers express a habit of the insect graphically when they say "It digs itself in," and, for this purpose, the beautiful musculature and the strong claws and spines of the legs are admirably adapted. The shirt is preferred, but in many cases most eggs are found at the fork of the trousers. This is because the trousers are worn consecutively for a much longer period than the shirt. In order of importance the areas most favoured for egg laying are the fork of the trousers and the armpits, the triangles at the tail of the shirt; next are the trousers and the shirt seams, and then the neck, but under present conditions there is general distribution also. Eggs have even been found in the beads of rosaries. It will be noticed that the insect accumulates where there is plenty of warmth, plenty of humidity, and plenty of shelter.

The possibilities of infestation are instanced in a case examined at hospital. Apart from extreme lousiness of underclothing, the man actually had lice and eggs at the back of the neck of the tunic, the pocket seams inside the tunic, and the flap seams of the pockets. A walking distributing agent!

Alimentation.

The insect feeds by sucking human blood, and adult lice may suck for twenty minutes at one time. They feed voraciously and wastefully, their excreta often consisting of what appears to be undigested human blood. The peristalsis is violent, and the whole alimentary canal may move backwards and forwards while feeding is in progress. Young lice feed immediately on hatching. In consonance with Warburton's experiments, it was found that the young may be reared by feeding twice a day on the arm. They suck for any length of time between nine and twenty-two minutes, averaging twelve. If allowed to feed three times a day they do not suck so long at one time.

The process seems to be—the stabbing organs are out-thrust, pierce deeply, and the sucking tube is anchored by the circumoral teeth to the skin; by means of muscular action on each pharynx the blood is drawn in; leakage into the sac of the stabbing organs is prevented by the upper stabber; the saliva pours into the sac, and, possibly via a tube formed by the upper and lower stabbers, reaches the wound and prevents the coagulation of blood; the blood is digested in the stomach and intestine; the waste

products from the gut and Malpighian tubules pass through the rectum and anus.

Life-History.

Concerning this it has not been possible to conduct many experiments. In copulation the male lies below the female, the penis is extruded, up-curved, and is retained in position by the gonopods of the female.

The eggs are about 0.8 mm. long and 0.3 mm. in diameter, and, according to Warburton, one female lays five at one sitting, and may produce a total of 125. They are clear and glistening when new, but towards the time of hatching appear a yellowish-brown, due to the colour of the developing insect inside. The experimental method of incubation was as follows:—small pieces of shirt seam bearing undisturbed eggs were placed in calico bags; these were tightly fastened with string to prevent the escape of any newly-hatched young; the bags were slung next the body under the armpits and examined twice a day, morning and evening. The conditions, therefore, were almost natural.

One exact result is of importance. A fortunate chance gave six newly-laid eggs. One young hatched out in six days, three in about seven days, one in seven days and a half, and one in eight days.

A total of 291 eggs, of unknown age, taken *in situ* on eight pieces of shirt which had been discarded for about one day, yielded, after two days' incubation, the following:

1. A constant succession of hatchings each day of 9, 23, 33, 24, 10, 11, 20, 7, 72, 5.
2. Total percentage hatched—82 per cent.
3. The greatest number took at least ten days to hatch. (Perhaps the one day's separation of the shirt from the body inhibited development.)
4. Incubation may often take at least twelve days.

The attempts to rear the young in calico bags carried at the armpits and by freeing to feed twice a day were not very successful. The results differ in certain respects from those of Warburton. The first moult took place at various periods—for example, about two days in one case, after three days in one case, five days in one case, and seven days in one case. One specimen lived fifteen days and moulted twice, the first time on the fifth day and the second time on the seventh. It looked only half-grown at the end of the time which Warburton suggests to be the limit of growth. The conditions of the experiments were almost natural, and the heavy mortality of the young is rather baffling and disappointing. It may be that the young are especially susceptible to even the slightest confinement.

Vitality.

The duration of life on the body is not known. Warburton kept a mature female alive for thirty days. This would make the total length of life about seven to eight weeks. The duration is said to be dependent upon three factors:—abundance of food, the normal body temperature, and body emanations. Kept at 37° C. dry heat in a bacteriological incubator, lice die in about three days. Specimens were fed twice a day and kept on a piece of clean shirt in a cardboard cylinder. This was carried under the armpit, so ensuring body temperature without body moisture. The insects died in about five days. Body moisture, therefore, seems necessary to the insects, but what is the more essential, the humidity only or the chemical quality, is not known to the writer. To these factors it is proposed to add freedom. Even under the very slight restraints imposed during experiments the adult insects died quickly, that is, in two or three days.

As a result of many experiments it was found that the longest period during which lice survived separation from

FIG. 2 (key to Fig. 1).

the human body was nearly nine days. The following results were noted:

On an infested shirt, newly discarded and exposed to the open, during which the temperature varied between 40° F. and 45° F., two days being raw and wet, lice lived as long as five days.

On infested shirts, taken singly and stored in large army biscuit tins, or in brown paper parcels, they may live about seven days; on shirts stored in bulk, eight days.

Placed upon freshly won soil, they lived seven days. On a piece of shirt which was placed upon soil in a large biscuit tin they lived eight days. Dry soil to the depth of 2 in. was placed at the bottom of a box 2 ft. x 1½ ft. x 1½ ft., and covering the soil were laid pieces of wood, so imitating in miniature the conditions of a dug-out. A lousy shirt was placed in the box. The lice congregated upon the uppermost part of the shirt and remained there alive for eight days.

A constant feature is the moribund condition into which the insects sink after two days' separation from the body.

This condition lasts till death. On taking a moribund louse, and placing it on the arm, there is evinced a quick response. The insect begins to take a distinct interest in life and shows it by perambulation and feeding. In connexion with this "warmth test" it is important to note that it may need to last quite five minutes at times.

With regard to vitality when subjected to various insecticides, the following results were noted:

Infested shirts dusted with a white mercury powder advertised as a vermicide, still held live lice at the end of four days. A similar test, using a powder of heavy oil residue (sulphonated), talc, and aloes, gave the result that the lice lived nearly nine days. The insects crawled regardlessly through both powders. Placed upon a small piece of shirt in a pill-box, the bottom of which was smeared with Vermijelli, they died in two hours, not having sense enough to keep away from the insecticide. They were killed by suffocation, their bodies becoming sticky with the preparation, and the stigmata choked. Similarly placed above N.C.I. powder they died in half an hour. A single infested shirt dusted with N.C.I. did not hold a live louse in ten hours. Shirts, each dusted with N.C.I. and stored in bundles of ten, each bundle being dusted above and below, did not contain live lice after three days. An infested shirt was immersed for half an hour in an emulsion of soapy water and crude paraffin oil (0.75 per cent. of emulsion being oil). The lice revived, and lived in pill-boxes for seven days.

The maximum time during which eggs away from the body may remain dormant has been found by Warburton to be about forty days. This was under laboratory conditions in England, and the temperature fell at times below freezing point. Similar experiments were carried out here, shirts holding eggs being exposed to weather conditions. Samples taken from one shirt which had been exposed for eight days hatched after four or five days' incubation on the body. During the time of exposure the temperature fell twice to freezing point, and two days were raw and wet. Samples taken from a shirt exposed thirteen days did not hatch after twenty eight days' incubation.

In applying this knowledge the important fact is that

eggs on the clothing, particularly the outer garments, if not treated regularly by ironing or disinfection, are a possible source of infestation for as long as a month after laying. Also, the removal of the clothing from the body for a few days in order to kill the eggs and lice by exposure, is not a practicable scheme.

The scanty existing information on the parasite's powers of endurance indicates them to be small. The examples cited, however, point to the conclusion that these powers are by no means inconsiderable.

The louse, therefore, is a parasite which is utterly dependent upon man's blood for sustenance and man's body and clothing for prolonged, prosperous longevity and reproduction.

INSTINCTS.

Migration.

To discover the capabilities of the louse with regard to its powers of locomotion and distribution the

following simple experiments were made. On four occasions, for a period of at least one hour, the tracks of four lice were charted. The diagrams (Fig. 8) illustrate two typical results.

The distance between the two lice farthest apart was 9 ft., two covering a distance, measured in a straight line, of 5 ft. The routes pursued were decidedly devious and exploratory. There was no desire evinced to make for a recently discarded shirt, which was laid as bait 6 and 12 in. from the insects. These charts demonstrate how, under certain conditions, the louse may go far afield to find a local habitation and a means of livelihood. It has been observed that the insects may climb the wall of a room to a height of 3 ft.

A box was made into a miniature dug-out; twenty lice were placed in it, and watched with very short breaks for eight hours. The insects scattered quickly, roamed round, and twelve in all left the box within half an hour. The remainder were lost. In another case, in which straw was placed in the box, only two migrated after two hours. After twenty-four hours two were found on the straw and six on the boards. The remaining ten were lost.

Such migratory powers are most probably only fully exerted in times of stress. This is borne out by their curious habits of "congregating." Whenever lice upon discarded clothing were the subject of experiment most of them invariably made for the uppermost portion of the material, and showed no desire to forsake it. There is therefore a decided preference for warm material. On a shirt in a condition generally termed "walking" were computed 10,000 live lice. This would indicate gregarious habit and comfortable inertia and that competition is no incentive to migration. Experiment also shows that light is not the stimulus to congregating.

Lice certainly do wander from the host. Although no experiments have been performed with the definite aim of ascertaining the stimulus of wandering, five months' experience with the insects suggests, that if the

FIG. 1.—The Clothes Louse—*Pediculus humanus*, Linnaeus (synonym, *P. vestimentis*). Male; black variety; enlarged about sixty times. Drawing made from cleared specimen, viewed dorsally, and seen by transmitted light.

surroundings of the host be warm and comfortable, lice are tempted to wander about. Such conditions exist in a warm bed or when soldiers are packed closely together. The insect, though moving about, is in its native air all the time, and there is not the adventure of changing an environment. In such circumstances a bed may be infected through the louse not being fortunate enough to return to

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 3.—Diagram showing anatomy of head; dorsal aspect. Drawn from sections and cleared specimens; sections cut by Lieutenant J. Shaw Dunn, R.A.M.C. (1) Protective sheath—imcomplete tube; (2) projecting anterior dorsal margin of head; (3) paired anterior ventral structures; (4) anterior ventral margin of head; (5) chitinous outer mouth-part, with (6) its tube running forward (7), and terminal teeth (8); (9) protractor muscles of outer mouth-part, and (10) retractor muscles (?); (11) first pharynx, and (12) muscles; (13) second pharynx, and (14) muscles; (15) the two structures of the inner mouth-parts, the dorsal being thin and broad, the ventral narrower and thicker, with three (?) terminal points; (16) ventral sac lodging the inner mouth-parts; (17) bifurcated posterior ends of inner mouth-parts; (18) protractor muscles (?); (19) retractor muscles (?); (20) oesophagus—dorsal; (21) supra-oesophageal brain, and (22) sub-oesophageal portion; (23) optic nerve; (24) eye.

FIG. 6.—Diagram to illustrate mouth-parts in action.

the host before he leaves the bed, and other men, clean or otherwise, may become infected.

Selection and Preference.

Lice soon find the body if the host sleeps on any infected bedding. The discovery of the host may be due to three causes: (1) The warming of the bed giving the incentive

to wandering; (2) contact of the lice and the body; (3) the insect "scenting" the host. Which is the most important factor is not known. A deliberate effort to reach the human body or recently discarded and sweat-impregnated clothing has never been observed. The instincts of detecting and pursuing the host seem, therefore, to be very feeble, if not absent.

FIG. 7.—Diagram showing internal anatomy of female; ventral aspect. Drawn from dissections and cleared specimens.

These instincts being at best so feeble it seems still more improbable that the parasite has any instinct of preference—that is, as popularly expressed, "choosing one person rather than another." Three types suffer most from lice—the person badly infested, the person with a very sensitive skin, and the person who has never been verminous before. The first type may be an unfortunate soldier, physically unclean through campaigner's luck, or may be a man of unclean habits, in both cases the parasites having every

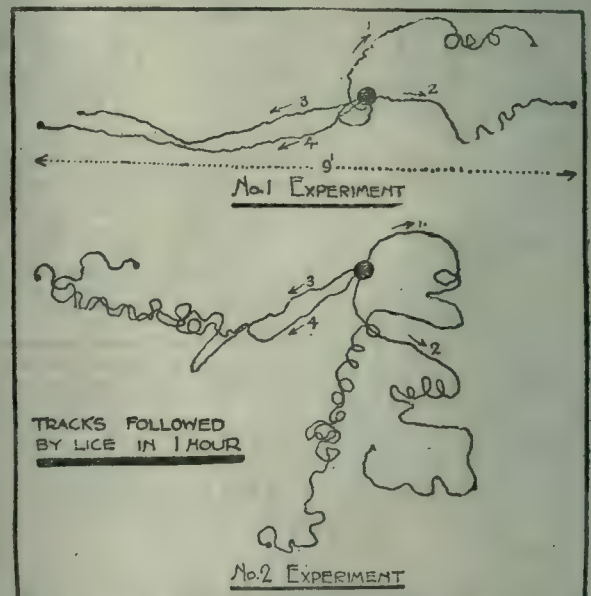

FIG. 8.—Tracks of lice; the breadth of the diagram represents 9 ft.

opportunity for success. In the other two types it is a matter of susceptibility to the touch and stab of the insects.

MEDICAL AND MILITARY SIGNIFICANCE.

Scratching, such as louse irritation induces, renders the skin prone to sepsis. "Louse rash," if it may be termed so, has been found distressingly common, and has frequently been mistaken for scabies.

Lousiness is felt mostly at night. This is in spite of

the fact that practically the same number of lice is present on the body during the day. Probably the distractions of the day keep the mind away from the pest, but at night, when everything is conducive to the desire for rest and comfort, the mind is most sensitive to the slightest irritation. Then the crawling of the insects, their sharp stabs, the itchiness of each tiny wound, and the fierce desire to scratch become intolerable. As one man said, "You feel as if you could rive yourself to pieces." Sleep, at best, is broken and uneasy, but is usually impossible. Consequent upon loss of sleep, impaired vitality and mental weariness become very real miseries to the soldier, the value of whom depends upon a high pitch of bodily well-being.

These are the soldier's most acute troubles, primarily due to lice at this front, but it must never be lost sight of that the menace of typhus, possibly more imminent at the Eastern fronts, is still present at the Western.

(To be continued.)

Notes on Military Orthopaedics.

III. THE SOLDIER'S FOOT AND THE TREATMENT OF COMMON DEFORMITIES OF THE FOOT.

BY

LIEUTENANT-COLONEL ROBERT JONES, CH.M.,
F.R.C.S.I. (HON.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

(Continued from page 711.)

PART II. CLAW-FOOT.

ONE of the surprises the military surgeon meets is the number of men with claw-feet who have been passed into the army; but still more surprising is the fact that many such cases have found their way to the front after the vigorous initial training which the recruit undergoes. Sooner or later, however, these men gravitate to hospital, and very few of them return to the ranks as efficient. A patient with this condition of the foot is quite unfit for military service, and should never be accepted as a recruit. The affection usually begins in early life, and is often not recognized until it has reached what I have termed its second stage; until then serious trouble hardly ever arises.

The etiology of "claw" or "hollow" foot is still uncertain. It is very often associated with a slight contraction of the Achilles tendon in childhood, and in some cases is due to a transitory paralysis of the extensor group of muscles. The short boot also stands in some causal relation to it. The whole question is, however, too vexed to be discussed here.

Clinically the condition presents five degrees or stages. The progress of the development of the deformity from one degree to another, though often continuous, is frequently arrested in one of the early stages; or perhaps the facts may be better stated by saying that progress from the first two stages to the later more severe stages is very slow, and sometimes does not take place.

1. The First Degree of Claw-foot.

The first degree occurs in childhood, and is easily overlooked. There is no visible increase in the height of the arch—in fact, the foot looks normal. The complaint made is that the child is clumsy, especially when running, and frequently stumbles or trips without obvious cause.

It will be found in such a case that the foot cannot be dorsiflexed beyond a right angle with the leg, and that there is commencing contraction of the Achilles tendon and the structures in the sole. The child's tendency to stumble is thus explained, for the fore part of his foot gets in his way as he tries to run.

The treatment in this stage is obviously to stretch the Achilles tendon and the plantar structures and so restore the power of dorsiflexion of the foot at the ankle. This can usually be effected by manipulation, after which the boot in which the patient walks should have no

heel to it, but a bar half an inch thick placed transversely under the tread. In some cases it may be necessary to lengthen the Achilles tendon. This is best done subcutaneously by the following procedure (Fig. 1). The tenotome is entered on one side near the heel, and one-half only of the tendon is divided. The tenotome is next entered one and a half to two inches further up on the other side, and the other half of the tendon is divided. Now, by forcible dorsiflexion of the foot, the two halves of the tendon are made to slide on one another until the required lengthening is obtained. A rectangular splint is then applied so as to keep the Achilles tendon at rest in the corrected position and to maintain tension on the sole of the foot. This method is always preferable to the other method of complete division of the tendon at one level as the period of convalescence is shortened, and functional power in the calf muscles is more speedily restored.

FIG. 1.—Anatomical diagram to illustrate the two stages of the operation for the lengthening of the Achilles tendon by subcutaneous tenotomy.

2. Degree of Claw-foot.

In the second degree there is definite contraction of the plantar fascia, and the characteristic deformity of the foot is easily observed (Fig. 2). The fore part of the foot is dropped—that is to say, there is flexion at the mid-tarsal joint or exaggeration of the arch of the foot. At the same time the great toe is dorsiflexed at the metatarso-phalangeal joint, and the tendon of the extensor proprius hallucis stands out prominently. Further, if the surgeon places his finger under the ball of the great toe he easily lifts it, and the toe automatically straightens out (Fig. 3). The other toes do not present a similar deformity at this stage, but the Achilles tendon is shortened. Even in this condition the patient may not complain of pain or disability; especially is this the case in the very young. In older folk, such as the recruit, complaints may begin whenever long marches are repeated. The men have to fall out because of pain and fatigue. They have frequently been suspected unjustly, for even at this stage there are no very obvious objective signs. The arch of the foot is not collapsed, but, on the contrary, slightly exaggerated. But if the surgeon makes a careful examination he will note tenderness beneath the metatarso-phalangeal range, and when the patient is asked to extend his toes the big toe responds to a disproportionate extent.

FIG. 2.—Claw-foot, second degree.

Treatment at this stage must be drastic. If the patient is to be rendered able to get about with ease and comfort, nothing less than operation will suffice. A radical attack may save the situation, and in a few weeks the soldier may return to duty. The operation consists in dividing and stretching the plantar fascia and then in making an incision over the tendon of the extensor of the great toe (extensor proprius hallucis), and the tendon is severed from its attachment. Two holes are drilled close to each other behind the metatarsal head, forming a tunnel through which the tendon is drawn by means of a catgut

FIG. 3.—Claw-foot, second degree. The surgeon's finger easily replaces the dropped head of the metatarsal bone of the great toe; a case in this stage is suitable for tendon transplantation.

ligature (Fig. 4). The tendon is then pulled so as to raise the dropped metatarsal head into position (Fig. 5), and its lower end is stitched to its upper part just above its entrance into the bone (Fig. 6). This completes the operation, but the foot must be firmly bandaged down to a metal sole plate with a thick roll of wool placed transversely just behind the heads of the metatarsals so as to flatten the arch as much as possible. The whole foot is then fixed in a shoe splint, which is bent to rather less than a right angle. After the stitches are taken out, the foot is put up in plaster-of-Paris in the fully corrected position, and the patient is allowed to walk in this for from three to six weeks. He should then for a few weeks wear boots with no heels, and a bar across the sole beneath the heads of the metatarsal bones so as to keep the foot dorsiflexed when walking.

FIG. 4.—Claw-foot, second degree. Operation by transplantation of tendon of the extensor of the great toe. The diagram shows how the tendon of the extensor proprius hallucis is introduced through the tunnel above the head of the metatarsal bone.

structures; the operation just described for the second degree would therefore be useless. Further, the other toes also are now dorsiflexed, and the characteristic deformity which at first was visible only in the great toe is now shared by all the toes. The movements of the toes are limited, and they are beginning to become rigid in the position of deformity. Corns and callosities are formed across the ball of the foot owing to the increased pressure of body weight, for in this stage the patient can hardly get his heel to the ground at all. The Achilles tendon and plantar fascia are still more contracted than in the first two stages.

Operative treatment has now to be carried out in two stages.

A. The first stage includes division of the plantar fascia and severe wrenching to flatten the foot as far as possible, but as at this stage all the metatarsal bones are very obliquely placed it is necessary also to remove bone. The operation consists in removing through separate incisions on the dorsum of the foot a half to one inch from the shafts of the first, second, third, and fourth metatarsal bones toward the bases without opening the joints. The fifth metatarsal is retained intact, as it forms a useful splint for the rest of the bones. Removal of the head of the metatarsal should be avoided. The extensor and flexor tendons should be divided.

FIG. 5.—Claw-foot, second degree. Operation showing the tendon of the extensor proprius hallucis passed through the head of the metatarsal bone of the great toe and pulled before fixing.

B. As it is impossible to correct all the cavus deformity in this way, at a later stage the Achilles tendon is divided by the sliding operation, and the foot wrenched into dorsiflexion. The after-treatment and alteration in boots follow the same lines as those already prescribed.

4. Fourth Degree of Claw-foot.

In the fourth stage, in addition to all the deformities already described the foot acquires a well-marked varus deformity (Fig. 8). Callosities are even more tender, and walking is painful and difficult.

Treatment has to be still more drastic. After dividing

and wrenching all tense structures so as to mould the foot towards the correct position, it will be necessary to divide also the flexor and extensor tendons, and then remove the astragalus. This releases the remaining tension on the sole, and the foot can be moulded into shape, so as eventually to carry body weight with comfort to the patient.

5. Fifth Degree of Claw-foot.

The last stage of claw-foot leaves the patient in a pitiable condition. The toes are blue and contracted, the callosities exquisitely tender. The deformity is that of equino-varus (Fig. 9). The patient longs for amputation. This should never be done, and I would recommend as a substitute an operation I have designed and practised with success on many occasions.

In such a case the astragalus should first be removed, and then a flap incision made along the base of the toes on the sole of the foot. A flap should also be raised from the dorsum of the foot, and the heads of the metatarsal bones exposed. The toes and the heads of the metatarsal bones are removed. The result of this operation is excellent (Figs. 10 and 11).

Although the various operative procedures I have described as necessary in the treatment of the later stages of "claw-foot" do not result in producing an efficient soldier, there is every reason that they should be known. The military surgeon

FIG. 7.—Claw-foot, third degree.

FIG. 8.—Claw-foot, fourth degree.

has to consider the usefulness of citizens when the war is ended, and operations such as I have described, with

FIG. 9.—Claw-foot, fifth degree. Front view after operation recommended in the text. The toes and the heads of the metatarsal bones, as well as the astragalus, have been removed.

appropriate variation, will be needed for many types of contracted feet following injuries received from the enemy.

FIG. 6.—Claw-foot, second degree. Operation for second degree, showing how the tendon of the extensor proprius hallucis, after traversing the tunnel in the bone, is attached to itself and secured.

HALLUX RIGIDUS, HALLUX VALGUS, AND METATARSALGIA.

The conditions known as hallux rigidus, hallux valgus, and metatarsalgia, or Morton's disease, are all frequently associated with flat-foot; they all have some features in common both as regards the nature of the pain experienced and the alterations required in the boot to relieve mild cases and to complete the after-treatment in cases which have required operation.

THE MARCHING BOOT.

Mobility of the Toe.

This is a convenient point at which to make a digression to discuss the importance of correct position and free mobility of the great toe in marching.

In young children of all races the great toe is directed slightly inwards towards the middle line of the body, in line with the anterior part of the inner longitudinal arch of the foot, to the structure of which attention was directed in the article on flat-foot published on May 20th (p. 709). In races who habitually go barefoot this position of the great toe is preserved in adult life. In civilized races—those, at least, who wear boots—the toes are often cramped into boots of unsuitable shape, so that the small muscles of the foot suffer atrophy from disuse, and the power to spread the great toe inwards in walking is much impaired. In a strong foot which has not been deformed by wearing pointed boots the great toe is spread inwards by the action of the abductor hallucis when balancing on one foot, when the weight of the body is on the fore part of the foot in walking, and still more so when carrying a pack on the shoulders.

Qualities of a Good Marching Boot.

A good marching boot should therefore leave the foot free to adapt itself to altering conditions of balance and strain.

First. The boot should fit comfortably and closely round the heel and ankle so as to avoid lifting of the heel in the boot, which results in chafing, ending in a blister of the heel.

Second. To save the arch from giving way and to avoid flat-foot the heel of the boot should be slightly higher on the inner side than on the outer. (See the article on flat-foot, p. 710.)

Third. The inner side of the boot should be straight right up to the tip of the big toe—that is to say, the inner sides of the two boots should be parallel to each other all the way along to the great toe. There should be no trace of pointedness, for pointedness tends to produce hallux valgus, and helps to cause flat-foot.

Fourth. The sole of the boot inside should be as broad as the foot with the weight of the body on it. In the case of a soldier it should be as broad as the foot is when carrying the weight of the soldier in full marching order—that is to say, the weight of the soldier himself, his pack, and all his accoutrements.

Fifth. The upper of the boot should not compress the fore part of the foot in any way. The toecap should be stiff and deep enough to clear the toes and allow free movement inside the boot. This stiffening should run back on the inner side of the boot to a point behind the metatarso-phalangeal joint of the great toe.

Sixth. The boot should be long enough to allow the foot to extend to its full length when the soldier is carrying his pack and all his accoutrements.

These last points, dealing with freedom of movement of the fore part of the foot, are essential to the full development of the small muscles of the foot on which the soldier's endurance and marching powers depend to so large an extent.

Corns do not develop in a foot encased in a boot which allows free play to the fore part of the foot. The regimental chiropodist is a most valuable asset, but his existence is, *ipso facto*, a confession that the fit of the men's boots is not all it might and ought to be. The man should not be allowed to judge of the tightness of his boot when his foot is cool. On the contrary, boots should be served out when men have come in from a long route march, and their feet are engorged with blood, and therefore at their largest. If this were done, interference with the circulation of the foot by the boot would less often occur. When a foot swells after a march, the

swelling is practically all in the fore part, not round the heel. To serve out boots, therefore, after a route march would not prevent a man from choosing a pair which fitted properly round the heel and ankle.

The present army boot is a great improvement on the boot served out at the time of the South African war, but it is still lacking in two points—namely, the straight inner side and the clear free stiffened arch in the upper of the fore part.

HALLUX RIGIDUS.

Hallux rigidus (Fig. 12) is a condition characterized by limitation of the power to dorsiflex the great toe at the metatarso-phalangeal joint.

If we remember that in straining on tip-toe or in stepping off with the foot in marching this joint must be dorsiflexed, it is evident that any limitation of the movement of dorsiflexion must, in the course of a long or hard march, result in straining the joint so that it becomes painful and inflamed.

As hallux rigidus and hallux valgus are both disorders of the same joint and are often intimately connected, the rigid toe may lead on to valgus deformity and a hallux valgus may become rigid. There is no essential difference in the pathological condition of the joint, but only in the direction of the deformity associated with it.

FIG. 12.—Hallux rigidus.

Treatment.

The treatment of hallux rigidus must be to restore the power of dorsiflexion of the great toe at the metatarso-phalangeal joint.

In the early stages, when the tenderness and inflammation either about the joint or in the joint has not resulted in osseous changes, palliative measures may still lead to recovery.

First the joint must be relieved of strain, so that the inflammation may be allayed. This can be brought about by arranging a bar like a football bar fully one-third of an inch thick and about an inch broad placed on the boot behind the head of the metatarsal bone. This causes the body weight to be borne on the neck of the metatarsal rather than on the tender joint, so assuring rest to the joint. As soon as the inflammatory tenderness becomes less the patient finds that the power to dorsiflex the toe begins to return. This is the moment to begin massage, movement, and hot and cold contrast bathing in order to hurry up the processes of repair.

In more advanced cases, and in cases resulting directly from trauma—as, for instance, dropping a weight on the joint or violently “stabbing” the toe, osseous changes due to formative periostitis occur round the joint. There may be lipping of the base of the phalanx, and usually some nodular thickening of the head of the metatarsal, especially in its upper aspect. This osseous outgrowth forms a mechanical block, preventing hyperextension. The impact of the bones on each other maintains the periostitis, and the condition gets progressively worse. Palliative measures may enable a civilian to go about his business with some degree of comfort, but he cannot do a day's shooting, and palliative measures are of no use for a man who must march.

Operation alone will remove the obstruction to movement and give permanent relief.

The operation follows exactly the lines to be described below for hallux valgus, and need not be described here.

HALLUX VALGUS.

Hallux valgus (Fig. 13) is a deformity of the first metatarso-phalangeal joint, the essential feature of which is that the great toe is deflected outwards, and in extreme cases may lie over or under the second toe.

One consequence of this position of deformity is that the head of the metatarsal and the base of the proximal phalanx form an undue angular prominence on the inner border of the foot. As a result of chafing and pressure by the boot a bursa, or bunion, forms over the thinned inner

part of the capsule of the joint. It may communicate with the synovial cavity.

The continued pressure and friction causes the skin over the bursa to become indurated and horny, and this greatly adds to the pain and discomfort suffered by the patient.

Frequently suppurative inflammation occurs in the bursa (septic bursitis); this may be followed by septic cellulitis with inflammatory thickening of the tissues round the joint or, in cases in which the bursa communicates with the joint cavity, it may lead directly to septic arthritis.

It has been a surprise to many surgeons that soldiers have been able to go through their training and even to serve in France with pronounced hallux valgus deformity. The reason is that the disability is not due merely to the visible deformity but to the addition of the following three conditions:

1. Inflammation of the bursa (bunion).
2. Traumatic arthritis, of the same type as the arthritis in cases of hallux rigidus.

FIG. 13.—Hallux valgus.

3. Tenderness due to pressure on digital nerves in every respect similar to the tenderness in a classical case of metatarsalgia or Morton's disease.

Of these three causes of disability bursitis is the most common; the dangers of septic bursitis communicating with the joint have already been noted.

Arthritis is much more rare, and is usually of the sub-acute type common in cases of hallux rigidus without the valgoid deformity. It is diagnosed by tenderness and pain on any movement of the joint, even gentle attempts at passive rotation of the toe.

The third variety, comparable to Morton's disease, is marked by acute pain on oblique pressure on the joint between the finger and thumb, and is due to excessive sensitiveness of the digital nerves and adjacent tissues outside the joint. It is not, as a rule, marked by any objective signs other than the valgoid deformity, and in cases of hallux rigidus of this variety there is no visible deformity—only tenderness on pressure on the joint.

It is difficult to make a sharp division between hallux rigidus and hallux valgus. The same types of pain and disability occur in both. It may, however, be said that with a distinct valgoid deformity it is comparatively rare to find rigidity, but that in cases of painful great toe without valgoid deformity—that is, in cases classed as hallux rigidus—arthritis and the resulting rigidity are much more common. Hence the difference in descriptive terminology—but to understand the conditions properly they should be taken together.

Treatment.

In mild cases palliative measures may suffice. First, the weight of the body should be taken off the joint by putting a bar—like a football bar—across the sole of the boot behind the head of the metatarsal. If the boots are specially made, this is worked into the thickness of the sole with a hollow in the sole for the great toe joint. The bar on the sole will, however, keep a man on his feet who would otherwise be disabled by pain in the great toe joint. The boot should, of course, be straight on the inner side, and the upper should spring clear up, leaving room for the large head of the first metatarsal—a feature unfortunately absent from the regulation boot. If the boots are roomy enough, a piece of felt with a hole in it to accommodate the bunion will afford relief.

Such measures, however, are only curative in the milder cases, and are not applicable to the man on service.

Operative Treatment.

Operative treatment of hallux valgus must not merely aim at correcting the deviation, but must also be directed to securing free dorsiflexion of the great toe, otherwise the patient will be left with all the disability of a hallux rigidus.

It follows, therefore, that, apart from the correction of the valgoid deformity, the operative procedure is practically the same in principle in both conditions, and one description suffices for both.

First let it be stated that there are two operations sometimes performed, which need only be mentioned to be condemned. The first is transplantation of the extensor proprius hallucis tendon to the inner side of the metatarsal head in the hope that it will correct the outward deviation. Experience has proved that this operation is generally useless; it is therefore a waste of time to perform it. The second operation—excision of the joint—cannot be too emphatically condemned, as it is liable to end in a stiff joint, bringing with it all the crippling disability of hallux rigidus in its worst form.

Finally, no operation should be performed while there is any inflammation of the bursa or surrounding tissues.

A. In early cases in which there is valgoid deformity but not much enlargement of the head of the metatarsal by bony outgrowths, osteotomy of the neck of the first metatarsal bone, either linear or cuneiform (Fig. 14), associated with tenotomy of the extensor proprius hallucis tendon will suffice.

B. In later stages, with bony excrescences round the joint, more free removal of bone and some form of pseudarthrosis must be performed to secure the free movement of the toe, which is essential to comfort.

1. Free excision of the head of the first metatarsal bone, with interposition of a flap of tissue, or of part of the bursa, is not satisfactory in a soldier, though it has proved satisfactory in civilians who do not have hard walking or marching to do. The reason is that the lower part of the head of the bone is an important part of the weight-bearing apparatus, and must be preserved.

2. The operation to be preferred is resection of the head of the metatarsal bone (Fig. 15), leaving as much as possible of the lower part, taking care to clear away all bony excrescences which obstruct dorsiflexion or full correction of the valgus deformity.

The bursal flap is then interposed as a covering for the raw surface of bone. At one time I used to interpose the whole bursal sac, but nearly twenty years ago several patients developed bursitis in the transposed bursa. The procedure I now adopt, therefore, is to open the bursa and interpose only one wall as a covering for the bone (Fig. 16), or obliterate the bursal cavity.

3. In some cases (more often in cases of hallux rigidus than in those of hallux valgus) it is possible to preserve the articular cartilage of the head of the metatarsal bone,

FIG. 14.—Hallux valgus. To illustrate osteotomy of the neck of the metatarsal bone, showing the wedge to be removed.

FIG. 15.—Hallux valgus. To illustrate resection of head of the metatarsal bone by oblique incision through the bone.

This may be done in two ways: The one method is to remove a wedge or slice from the posterior part of the head and then apply the cartilage to the raw surface of bone.

FIG. 16.—Hallux valgus. Showing flap to cover the end of the metatarsal bone in the operation illustrated in Fig. 15

The other is to cut a wedge of bone with the cartilage and mortise it into a cleft made in the bone further back, removing the intermediate bone.

In every case division of the extensor proprius hallucis is an essential part of the operation for hallux valgus,

otherwise the traction of this muscle will tend to reproduce the deformity.

Technique of the Operation and After-Treatment.

The skin incision should be a linear incision along the inner side of the joint. The flap incision round the bursa described by Mayo has not proved entirely satisfactory in my experience.

The skin having been freed and retracted, a flap incision is made in the underlying tissues with a second knife. The knife used for the skin may be infected with *Staphylococcus albus* from the skin; it is therefore a wise precaution never to use the skin knife for any deeper dissection, especially in plastic operations where the least infection may destroy the value of the operation.

The joint is thus opened, and the head of the metatarsal freely exposed. The surgeon can then decide how much bone he is to remove and exactly how the wedge is to be made so that the toe will be correctly in line after the operation. He can also decide whether he can usefully retain the articular cartilage or is to dissect out a flap of the wall of the bursa to cover the raw bone.

It should be noted that the sesamoid bones should rarely be removed, as they seem to form an essential part of the tread of the ball of the great toe. The pad of fat between the sesamoid bones is, however, sometimes thickened, red, and tender; if so it may be clipped away.

The whole operation must be carefully carried out with the most scrupulous attention to three points:

1. Preservation of part of the lower or weight-bearing portion of the head.
2. Restoration of free dorsiflexion, or the soldier will not march freely.
3. Correction of the valgoid deformity in cases of hallux valgus.

The valgoid deformity is purposely placed last, for in a sense it is the least important from the point of view of restoring the man's marching power.

A hallux valgus splint should be applied at the end of the operation. The splint I use is made of thin metal, as shown in Fig. 17. The hole in the splint fits over the inner side of the head of the metatarsal bone and prevents pressure from occurring at this prominent point. The base of the splint is strapped or bandaged to the inner side of the foot. The toe is then drawn inwards and secured to the narrow end of the splint, care being taken that the alignment is correct.

After-treatment in cases of hallux rigidus and hallux valgus is quite as important as the operation if we are to succeed in restoring function. Three

weeks after the operation the patient may walk, provided he has a proper boot. Gradual exercise and the correct bearing of the body weight in a properly designed boot is an essential part of the treatment.

The boot, in the first instance, should be made of soft material with a stiff leather sole. On the sole is put a

leather bar $\frac{1}{4}$ in. thick and $\frac{1}{2}$ in. to 1 in. wide behind the heads of the metatarsal bones. The body weight thus falls for the time on the necks of the metatarsals rather than on the heads. Further, the heel should be made $\frac{1}{2}$ in. higher on the inner side than on the outer side, in order to deviate body weight to the outer side of the foot and relieve strain on the inner side and great toe. This is, of course, also the appropriate treatment for the flat-foot so commonly associated both with hallux valgus and rigidus. The inner border of the boot must be straight, so as to allow the toe to be drawn inwards freely, so that no pressure of the boot will tend to reproduce the valgus deformity.

As a rule, patients shod in this way can walk at once with comfort. Later, an ordinary boot may be altered in the same way. The operation area is too tender to bear the pressure of leather for two or three weeks after operation.

It is while walking in these boots, with the body weight carried on the outer edge of the foot, that the real cure takes place. Under the normal physiological stimulus of walking repair is hastened, and the small muscles of the foot recover strength.

To let the patient get up in a slipper is absurd, for the weight falls then on the head of the metatarsal, and by irritating the new bone formed at the site of operation it sets up a fresh process of osteo-arthritis, which may leave him worse than he was before. The patient must therefore be strictly kept reclining, and never allowed to set foot to the ground till the time has come when he may be allowed to walk in a properly altered boot.

A CASE OF ARTERIO-VEIN ANEURYSM OF THE SUBCLAVIAN ARTERY AND VEIN

TREATED BY EXCISION OF THE SAC AND THE SECOND AND THIRD PARTS OF THE ARTERY.

BY

COMYNS BERKELEY, AND VICTOR BONNEY,

M.C. CANTAB., ETC.,

M.S. LOND., ETC.,

HONORARY SURGEONS IN CHARGE OF THE MIDDLESEX CLEARING HOSPITAL, EASTERN COMMAND, AT CLACTON-ON-SEA.

ARTERIO-VEIN aneurysm of the subclavian artery and vein has been until this war an unusual condition, and records of its treatment by operation appear to be very rare, if not entirely wanting.

A private of the Cameron Highlanders was admitted to the Middlesex Clearing Hospital, Eastern Command, Clacton-on-Sea, on October 1st, 1915. He had been wounded in Flanders on September 26th, a rifle bullet striking him just outside the axillary border of the right scapula near its inferior angle, and emerging just above the middle of the right clavicle. The wound of entrance was healed and the wound of exit practically healed, but underlying it in the subclavian triangle was a pulsating swelling about the size of a double walnut. There was a very marked thrill, which could be felt and heard even as far as the bend of the elbow. The right arm was entirely paralysed.

A diagnosis of arterio-venous aneurysm of the third part of the subclavian artery and vein and injury to the brachial plexus was made, and as the swelling in the neck was steadily enlarging and the patient was painfully conscious of the loud thrill, it was decided to operate.

Operation.

An angular incision was made: its lower limb ran along the clavicle, while the upper followed the middle line of the sterno-mastoid muscle; a skin flap was turned up which included the wound of exit. The external jugular vein, which was greatly distended, was ligatured in two places and divided. The deep fascia was then incised, but in doing so the sac of the aneurysm, which lay immediately underneath, was opened and a great gush of blood followed. This was restrained by pressure with a finger while the clavicular fibres of the sterno-mastoid were divided.

An attempt was now made to reach the artery on the proximal side of the sac, but owing to the cramped space and infiltrated state of the tissues it failed, and a second

FIG. 17.—Splint for hallux valgus after operation.

puncture was made in the sac, the outflow of blood from which was restrained by the pressure of a second finger.

The clavicle was resected between the costo-clavicular and the coraco-clavicular ligaments. The subclavian vein was then exposed at its junction with the internal jugular vein, and in the angle formed by that junction the first part of the subclavian artery was isolated and divided between two silk ligatures outside the origin of the thyroid axis.

By means of the outermost ligature (left long to act as a tractor) the distal portion of the artery was pulled forwards and outwards until the inner edge of the scalenus anticus was reached; the superior intercostal artery was divided in the process. The muscle being divided with scissors, the second portion of the artery was pulled up, and it became possible to insinuate the finger between the third part of the artery and the first rib, and raise it and the sac forwards.

One blade of a long artery forceps was thrust in behind the raised mass, along the upper edge of the subclavian vein, and the forceps being shut, the tissue was divided parallel with the blades.

The bleeding, which had been considerable in spite of the digital pressure exercised on the holes in the sac, now ceased, and it was possible to separate deliberately the sac from the lower cords of the brachial plexus. A ligature was then placed on the uppermost part of the axillary artery, and the mass of tissue, which consisted of the aneurysmal sac, and the third, second, and part of the first portions of the subclavian artery, was completely cut away. The forceps, which had been applied along the subclavian vein, and which controlled a small hole in its wall, was replaced by a lateral ligature.

All the bleeding now stopped; the exsected clavicle was wired into position, and the skin flap was sutured back after the exit wound had been excised. None of the cords of the brachial plexus appeared to have been divided by the bullet, but the patient's condition and the infiltrated state of the tissues precluded very thorough examination.

Dr. Beattie administered the anaesthetic most skilfully.

Description of Parts Removed.

The sac lay between the third part of the subclavian artery and vein, and communicated with both. The aperture into the vein was fortunately small, and was situated about the point where the external jugular joins it. The sac wall was very thin. Its front part was formed by the deep cervical fascia; behind and above it adhered to the brachial plexus, while the first rib and clavicle had limited it below.

After-History.

There was some shock, but although the pulse could not be felt either at the wrist or at the bend in the elbow, or in the line of the brachial artery, no gangrene or even discoloration of the arm occurred. Slight oedema of the upper arm appeared about a week after the operation, but subsided in a few days.

The result of the replacement of the exsected clavicle was not successful; suppuration occurred in the wound after the lapse of ten days, and the bone, failing to unite, had to be removed nearly a month later.

On the twelfth day fairly free bleeding from the wound took place; it was stopped by pressure. During November and December the patient had six further haemorrhages, the blood on each occasion flowing from a deep sinus that probably led down to the ligature on the end of the subclavian artery. The bleeding could always be stopped by

pressure on the mouth of the sinus. The amount lost varied; on the fifth occasion it was so severe that the patient required intravenous saline infusion, and as a result of these losses of blood he became extremely anaemic and ill.

Re-ligature of Subclavian Artery.

The last haemorrhage occurred at the end of December, in the early hours of the morning. The case appearing desperate, one of us (V. B.) who was on duty at the time, determined to tie the innominate artery. An incision was made along the anterior edge of the sterno-mastoid, and from thence downward somewhat over the sternum. The lower portion of the common carotid was exposed and freed from its sheath, and, by means of a loop of silk passed under it, the vessel was pulled up until the point of origin of the subclavian artery was reached. A second loop was then passed under the latter vessel, and by making traction on both loops the innominate artery was brought fairly into view. It was then found that traction on the loop passed under the subclavian artery arrested the pulsation which till then had been visible at the site of the sinus. The innominate artery was therefore not tied, but a catgut ligature was placed on the subclavian about one-quarter of an inch from its origin from the innominate.

No ill results followed this operation, although the new wound suppurated slightly, nor was there any further bleeding from the sinus. A small amount of haemorrhage from the new wound took place some three weeks after the second operation, but there was reason to believe it was caused by the patient fingering the part.

Present Condition. Both wounds are practically healed. No abnormal pulsation can be found in the neck, nor any pulsation at all in the arm, which is normal in warmth and colour. The arm, however, is still paralysed, though there is some return of power in the muscles of the shoulder and the flexors of the forearm. There is loss of sensation over that part of the hand supplied by the ulnar nerve.

PREVIOUS CASES.

Several cases of arterio-venous aneurysm of the subclavian have already been published during the present war, but none of these had been operated upon. From the South African war one case is recorded by Makins, the history of which is very interesting.¹

Arterio-venous Aneurysm of the Subclavian.—This patient had a pulsatile swelling with a thrill which was considered to be an arterio-venous aneurysm of the right common carotid, just at its origin from the innominate artery.

No operation was performed, and the man was invalided out of the service. After a considerable period he improved sufficiently to be able to do light work, and although the swelling still remained, the thrill gradually disappeared.

Nine years afterwards he began to have cerebral attacks deemed to be due to small emboli originating in the aneurysm sac. Distal ligature of the common carotid was therefore performed, but the patient died during the operation. *Post-mortem* examination showed a large aneurysm of the subclavian artery. The communication with the vein had closed.

Traumatic Aneurysm of the Third Part of the Subclavian Artery.—A case of this condition, not, however, communicating with the vein, has been recorded lately.² Ligatures were placed on the first part of the artery and on the brachial artery, but the patient died of respiratory failure before the operation was concluded.

REMARKS ON THE CASE HERE RECORDED.

We decided to operate because (1) the sac was obviously enlarging, and (2) if the enlargement continued the difficulties of the operation would speedily have become so great as to make any such attempt useless.

A perusal of Makins's case—the only one in which the

Diagram to show the position of the sac, and the ligatures. S = Scalenus anticus. R = First rib. (1) Position of first ligature applied to the subclavian artery; (2) ligature on uppermost part of axillary artery; (3) lateral ligature on subclavian vein; (4) position of second ligature applied to the subclavian artery.

after-history of an arterio-venous aneurysm in this situation is available—and the successful result we have attained appear to us to justify our decision.

We had to choose between, on the one hand, attempting to place a ligature on the artery on either side of the sac and, on the other, excising the whole sac and the involved portion of the artery. We chose the latter alternative because of the difficulty in isolating and ligaturing the artery sufficiently near to the sac (especially on the distal side, on account of the enormously dilated veins) to ensure against collateral channels re-establishing circulation into the sac.

If we ever have to perform the operation again we shall not replace the resected clavicle, for we think that if we had not done this the suppuration which determined the subsequent haemorrhages from the ligatured end of the artery might not have occurred. It would have been better not to have used silk for the main arterial ligatures. In military surgery, where asepsis of the wound can rarely with certainty be attained, catgut of an absorption rate of not more than twenty days should be used for large arteries, so as to minimize the duration of a ligature sinus if such occur, and which, so long as it exists, is a menace of haemorrhage.

NOTES ON A CASE OF PENETRATING WOUND OF THE HEART.

BY

R. GARSIDE DIXON, M.B., CH.B., CAPT. R.A.M.C.(T.F.),

SURGICAL SPECIALIST, CASUALTY CLEARING STATION (T.F.), ON ACTIVE SERVICE; HONORARY SURGEON, BINGLEY COTTAGE HOSPITAL;

AND

P. McEWAN, M.A., M.B., CH.B., F.R.C.S. EDIN.,

CAPT. R.A.M.C.(T.F.),

CASUALTY CLEARING STATION (T.F.), ON ACTIVE SERVICE; HONORARY ASSISTANT SURGEON, BRADFORD ROYAL INFIRMARY.

The following case is the only example of a wound of the heart in a series of 123 wounds of the thorax and its walls which have passed through this casualty clearing station during the last ten months. The great majority of penetrating wounds of the lungs have progressed sufficiently well to be sent to the base, and it is a recognized fact that most of these cases ultimately recover. Probably nearly all cardiac wounds produce death from haemorrhage too quickly to allow of the patients being removed alive even to a short distance from the battle-field.

In the case recorded here the patient was wounded, whilst in the upright position, by a rifle grenade, at 12.15 a.m., on March 23rd, 1916. He was admitted

to this hospital the same day at about 7 p.m., with a diagnosis of "gunshot wound of chest and right arm, compound fracture left elbow." His tally showed that he had had hypodermic injections of antitetanic serum (500 units) and of morphine ($\frac{1}{2}$ grain) at the field ambulance.

On admission, he was cold, suffering very severely from shock, short of breath, and cyanosed, but his lips were pale. Temperature 101° F., pulse 112, respiration 28. He was too ill for his wounds to be dressed then, but with brandy, salines, and hot-water bottles he improved sufficiently to have this done the following morning. His left arm, which was fractured, was transferred from a straight splint to a Thomas's, and the wound of his right arm, which was slight, was dressed. There was a small wound $\frac{1}{2}$ in. to the inner side and $\frac{1}{4}$ in. above the left nipple. A catheter was passed, and about a pint of normal urine drawn off. The patient was still very short of breath, and the dressing of his wounds was as much as his condition

In regard to ligature of the first part of the right subclavian artery, it is much easier, with an aneurysmal condition of the third part, to gain access to it inside the jugular vein and just outside its point of origin from the innominate, as was done at the second operation, than to secure it outside the jugular vein, as was done at the first operation.

At the bottom of the neck on the right side the jugular vein diverges outward from the carotid, leaving a small triangular space, crossing the base of which the subclavian artery will be found.

The upper end of the innominate artery and the root of the subclavian artery often lie well below the level of the manubrium sterni (they did in our case), but access to the latter can be attained by strong traction on the carotid and to the former by additional traction on the subclavian after this is found and isolated.

So resistant to trauma are large arteries that even strong traction on a considerable length of vessel stripped of its sheath and entirely isolated does not result in any harm.

would permit of. At 2 p.m. the pallor increased, he became more cyanosed, and his breathing more difficult. His temperature rose to 102° F., pulse 130, respiration 45. At 6 p.m. morphine $\frac{1}{2}$ gr. was given hypodermically to relieve the distress caused by the shortness of breath. He was semi-conscious all the time he was in this hospital. He knew his name, regiment, and home address, but kept on trying to get out of bed, and was often delirious. He never complained of any pain either in the chest or arm, but suffered considerably from thirst. The heart sounds were normal. There were signs of fluid in both pleural cavities, more on the right than on the left side. There was neither cough nor expectoration. The cyanosis deepened, the pallor and dyspnoea increased, and he died at 11.45 a.m. on March 25th, having lived 59 $\frac{1}{2}$ hours after receiving the injury, and having during that time been conveyed from the regiment to the field ambulance, and from that unit to this clearing station.

Necropsy.

The body, which was examined four hours after death, before the onset of rigor mortis, was that of a well-built man of medium height and good muscular development. The skin was pale, but cyanosed, and there were no wounds other than the three already mentioned. The wounds of the left elbow and right arm were of no pathological interest, and could not have been factors of any importance in causing death. A small external wound, situated just above and internal to the left nipple, was traced transversely inwards for about two inches through the subcutaneous tissue and chest muscle; its subsequent course was through the sternum, leaving the internal mammary artery intact; then through the edge of the left lung, the pericardium, the right ventricle, and the pericardium; finally the missile was found imbedded in the right lung. It was

not removed for examination, but its small size could be judged from an x-ray photograph.

The left pleural cavity contained a considerable quantity of blood, but the lung was of nearly the normal size; the right pleural cavity was almost full of blood, and the lung was found to be collapsed. The blood was fluid except for a single clot on the right side. The left lung had a slit-like wound of entrance, detected with difficulty, half an inch from the margin, at the inner and lower part of the anterior surface of the upper lobe, and a larger wound of exit through the margin of the inferior surface; about half an inch of the lung tissue had been passed through. There was a patch of recent fibrinous pleurisy between the upper and lower lobes, extending for about 2 in. on to the anterior surface of the lower lobe. On the under surface of the middle lobe of the right lung, about half an inch from the inner margin, a small piece of metal could be seen lying in the lung substance. There was no recent pleurisy, but the upper and middle lobes were almost completely fused by dense old adhesions.

A, Probe through wound in left lung. B, Probe through two wounds in pericardium. C, Probe through entrance wound in right ventricle. D, Probe through exit wound in right ventricle. E, Piece of metal in right lung. F, Wad of cotton-wool to evert margin of right lung to show piece of rifle grenade.

Description of Cardiac Wounds.

The pericardium showed an entrance and an exit wound over the right ventricle. On opening the sac a small piece of khaki cloth was found, together with a small quantity of clotted and fluid blood. The pericardium presented the appearance of early pericarditis. The left ventricle was distended, but the right was partially collapsed, and near the centre of its anterior surface was a small circular wound of entrance which passed obliquely through the muscle to a wound of exit very near to the right border of the heart; an interval of an inch separated the two wounds, and round each was a small circular area of bruised tissue. The right ventricle was opened posteriorly and found to contain some very bright red blood clot. No wound was visible from the interior, and on passing a probe it was found that the wound passed through one of the lacunae between the pillars of cardiac muscle, having just penetrated the ventricular cavity.

The cause of death was severe haemorrhage, complicated with pulmonary collapse and interference with the heart's action. The enormous amount of blood in the pleural sacs came from the heart; the lung wounds were not capable of causing much haemorrhage. With each systole some blood would be forced through the small openings in the right ventricle into the pericardial sac, and from there blood would ooze through the pericardial openings into the pleurae. There was no attempt at closure of the openings by clot. Their small size accounts for the length of time the patient survived.

The occurrence of pericarditis and pleurisy (the latter being curiously localized) showed the beginning of an infective process.

The wounds of the left lung were no doubt closed by blood clot, while that of the right was kept open by the shrapnel on the surface causing collapse.

An x-ray photograph of the specimen was taken by Captain F. H. Gibson, R.A.M.C., and no foreign body other than the one described was found.

The specimen has been sent to the War Museum of the Royal College of Surgeons, London.

WHITE GANGRENE.

BY

MAJOR A. J. HULL, F.R.C.S., R.A.M.C.

In addition to gas gangrene and gangrene due to direct interference with the blood supply, septic gunshot wounds may be attacked by a very acute infective process which is a form of gangrene. The condition appears to be an acute streptococcal infection, and is, in appearance, not unlike phlegmasia alba dolens, but is attended by the local circumstances associated with gangrene and the general effects of an acute toxæmia.

This form of gangrene has only been seen in the lower extremity.

The skin is glazed and white, moist, cold, and pits on firm pressure. A very firm oedema is present, and the distal pulse in the limb cannot be felt. The glazed white appearance of the distended skin, instead of the usual redness, seems particularly characteristic. Early in the condition the patient is extremely ill, with clammy, sweating face, and running pulse. The condition is extremely fatal, and death occurs in about twelve hours. The infection is so rapidly fatal that little change in the colour of the limb has been noticed. In those cases which have survived somewhat longer, it has been found that, during the last few hours, the limb has become mottled black and the discharge exceedingly foul. No gas has been noticed in the discharge, and no crackling has been detected in the tissues. The appearance is somewhat suggestive of deep-seated pus, owing to the tension of the skin, but, on making an incision into the limb, the wound merely oozes serum.

In the more severe and extensive forms the infection is so severe and the patient's condition so serious that no treatment appears practicable.

Amputation gives the only chance of recovery, and is successful when the infection is more localized, as happened in Case I.

White Gangrene of the Leg.

CASE I.—Pte. S., wounded March 9th with rifle grenade, dressed at field ambulance and transferred to base. Shell wound of left leg with comminuted fracture of upper third of tibia and fibula, and flesh wounds in the region of knee. Leg swollen and white, extending well up to thigh, and looking like

phlegmasia alba dolens. Foot cold, and no pulsation to be felt in distal vessels of ankle; wound foul with sanious discharge; temperature 102°, pulse 124. Bacteriological examination showed streptococcus. Amputation through lower third of thigh; recovery (Lieutenant S.'s case).

CASE II.—Pte. L. was shot through the calf on September 24th and admitted to a base hospital on September 25th. There was a small wound of entrance and a wound of exit the size of half a crown, through which muscle bulged; the leg was white, the skin tense and cold. Incisions, 3 in. long, were made on each side through the bullet track, capillary bandages were inserted, and continuous saline irrigation applied. The next day the skin was much more swollen, it pitted on firm pressure, and had the appearance of a limb containing deep-seated pus but was white in colour. Very little pus came from the wounds; a thin, foul-smelling discharge exuded. The patient's temperature was 103°; he was restless, and his general condition was very much worse. Numerous incisions were made into the subcutaneous tissue. The patient's condition did not improve, the pulse became rapid, shock was very pronounced. The limb turned blotchy black and was extremely foul. The usual remedies were employed, including rectal saline injection. The patient died eight hours after the second operation.

CASE III.—Cpl. W., admitted to hospital suffering from a shell wound of thigh. There was a compound fracture of femur and severe destruction of the knee-joint. The wounds had been cleaned and dressed with cyanide gauze at a clearing station. About fifty-six hours after the injury the patient had a rigor. His temperature rose to 104° F.; vomiting and collapse occurred. The limb became cold and no pulse could be detected. The skin was white in colour, and a firm oedema rapidly occurred in the whole limb. No crackling was present, indicative of gas. The patient's condition did not admit of surgical interference; and he died twelve hours after the appearance of the gangrene. Bacteriological examination discovered streptococci in the blood and in the discharge from the wound.

SIMPLE AND INEXPENSIVE METHODS FOR
FERMENTATION TESTS AND FOR
OBTAINING CULTURES OF
ANAEROBES.

By J. M. BEATTIE, M.A., M.D.,

PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF LIVERPOOL.

In most bacteriological laboratories the work during the war has been very much increased, and with the increased cost of apparatus and media various devices have had to be employed to reduce expenditure. It may, therefore, be of interest to record two methods which I am using, and which are simple, inexpensive, and, at the same time, efficient.

1. For Fermentation Tests.

For these I use small test tubes, which can be made in the laboratory from ordinary glass tubing of $\frac{1}{4}$ in. or $\frac{3}{8}$ in. diameter. Introduce into these tubes about $\frac{1}{2}$ c.cm. of any of the sugar media. These tubes, plugged and sterilized in the ordinary way, are inoculated with the organism whose reaction is to be tested, and then some sterilized vaseline, which has a melting point of about 55° C., poured into the tube. The vaseline solidifies and forms a plug, lying in contact with the fluid media. The tubes are then incubated in the ordinary way, and where gas is formed the vaseline plug is pushed up in the tube, and, if the media is cold when inoculated, there is sufficient absorbed oxygen to allow the free growth of the organism and to allow the reddening (the acid reaction) to show. In twenty-four hours, with the ordinary acid and gas-producing members of the typhoid-coli group, the reactions are very definite. Later, reduction takes place and the media becomes colourless, but if a hole is bored through the vaseline plug to allow ingress of air the red reaction reappears in a few minutes, starting at the upper part of the media and gradually spreading downwards. This method is simple and inexpensive, and it has the added advantage over the ordinary method that small quantities of gas, which may not be indicated by the ordinary Durham tube method, are always detected, the gas showing as small bubbles at the lower part of the vaseline plug. The method may be used for accurate estimation of the amount of gas produced by any given organism.

2. For Anaerobic Cultures.

Ordinary test tubes containing peptone broth or glucose peptone broth are used, and for the common anaerobes I find the peptone broth quite satisfactory. Melted sterilized vaseline is poured into the tube till it forms a

plug about $\frac{1}{2}$ to $\frac{3}{4}$ in. long. The broth and vaseline are then boiled for twenty to thirty minutes, so as to expel any absorbed air, and allowed to cool. The vaseline solidifies very rapidly and forms a very effective plug. The tubes can be kept for any length of time and are perfectly airtight.

When they have to be inoculated, they are put in a water bath at about 55° C. in order to melt the vaseline, and the infective material is introduced into the broth by means of a sterile pipette. Immediately after the tube has been inoculated it is my practice (though I think in most cases this is unnecessary) to heat the vaseline over the Bunsen flame before putting in the incubator, in case of infection of the surface vaseline during inoculation.

I have used the method for the common anaerobes, and I have never failed to get a good growth in twenty-four hours. The method has the advantage over the ordinary anaerobic methods of simplicity and cheapness, and I really adopted it because of the increased cost of and the difficulty of obtaining the reagents which are usually employed in anaerobic culture. It has a further advantage that the development of even mere traces of gas can be detected. For examination of the culture, the plan I use is to puncture the vaseline with a thinly drawn-out pipette sealed at the lower end, and constricted about half an inch from the sealed end. By pushing the pipette against the bottom of the tube it easily breaks at the constriction, and any quantity of the fluid culture can be drawn up. After the pipette is withdrawn the vaseline is melted and the tube is again tightly sealed.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE CAUSE OF APPENDICITIS.

PROFESSOR SHATTOCK'S paper in the Section of Pathology in the Royal Society of Medicine, which treats of the mechanical causation of appendicitis (p. 690), is of special interest to me. Having had it myself, a few facts as to my experience may help those who are trying to find out the true cause. Towards the end of 1881, when in practice at Eccles, I began to suffer from insomnia. If I fell asleep when I went to bed I awoke about 4 o'clock next morning, and could not sleep again; whereas if I did not sleep on going to bed, it was about 4 o'clock before I slept. That fact points to a periodicity which ought not to be overlooked. I did not feel ill, and went about my work as usual until about the middle of December, when I went to my ancestral home in Scotland for a holiday, hoping to get rid of the insomnia. While there I was out all day, generally with the gun. I ate as usual and the bowels acted every morning, but I was conscious that there was some difference in the motion. It was a spluttering motion, from flatus passing with the faeces. After ten days I returned to Eccles on December 24th. Having had breakfast before starting, I might have had a sandwich on the journey, and when I got home I had an egg, a slice of white toast, a cup of tea, and went to see a patient who was very ill. Going to bed at my usual time I fell asleep, and awoke about 4 a.m. with pain in the left side of the abdomen. I took a dose of castor oil, and was sick, but had no motion. In three days, having been in bed all the time, appendicitis was diagnosed by the late Sir William Roberts, who advised me to keep to peptonized milk as food and to have morphine to relieve pain. I had general peritonitis, and for twelve months afterwards could feel a lump, the size of a hen's egg, just inside the superior crest of the ilium, where, according to my observation, and not at McBurney's spot, the appendix lies. Having been about three weeks in bed I went to Scotland to recruit. I was astonished to find that my memory, which was very good before that illness, had failed. I have never had another attack, but ever since have had to be careful as to diet, and was induced to study the physiological action of foods for my own sake. As a result I published what I called *A Doctor's Discovery*, which, although not new, was quite original on my part; and there I think I prove that food is the chief cause of disease. Having got rid of all unnecessary fat I can feel my caecum, and, watching the effect of food on it, I find that vegetables

make it large and flabby, just like an uncontracted uterus after confinement; while on fruit it is small and firm, like the well-contracted uterus.

It was by mere accident that I came to the conclusion that animal food was not good for me, and I have been a vegetarian since 1896.

Professor Shattock from his researches concludes that vegetarianism—the recent rise of which he has recognized—may be the cause of appendicitis, leading to an increase in the formation of appendicular concretions. That conclusion, taken in connexion with my observations on the different effect of vegetables and of fruit upon the caecum, points towards food as having to do with the increase in the number of cases of appendicitis, and may help to direct the attention of physiologists to the physiological action of our common foods—a subject hitherto entirely neglected.

Denholm, Hawick.

JOHN HADDON, M.D.

Reports of Societies.

TOXIC CAUSES OF IDIOCY AND IMBECILITY.

At the ordinary quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland, held at the rooms of the Medical Society of London on May 16th, when Lieutenant-Colonel DAVID G. THOMSON, President, was in the chair, two papers were read by Dr. Orr (Prestwich) and Major Rows, R.A.M.C. (Maghull, Liverpool), on experimental toxic lesions in the rabbit's brain and their bearing on the genesis of acquired idiocy and imbecility in man. Dr. ORR said that the communication was a continuation of experimental work on the action of bacterial poisons on the nervous system. In the former work the induced toxic action was studied in the spinal cord only; in the present series the research had been extended to the brain, a capsule containing *Staphylococcus aureus* being placed in contact with the common carotid artery in the neck. The positive results so far obtained helped to explain the pathogenesis of certain obscure lesions of the central nervous system in man. Rabbits were used for experiment. The alterations seen as the result of the poison were typically those of coagulation necrosis. The neuroglia participated actively in the inflammatory reaction, and around the area of softening there was found to be much neuroglial proliferation and hypertrophy. There was a high degree of proliferation of the adventitia of the small vessels in the immediate vicinity of the softening. The research showed that the two factors, degree and situation, could produce dissimilar pathological results although the pathogenesis was the same. Applying this to clinical neurology it became evident that certain nervous syndromes, though widely different in symptomatology, were, pathogenetically, one and the same disease, the different symptomatology being largely due to the anatomical site of the lesion. The experiments also shed light on the genesis of the infantile cerebropathies, now regarded as due to toxic-infections of medium intensity contracted between the fifth and the eighth month of fetal life, or, more rarely, in early infancy.

Major Rows, M.D., said that the term "vegetative system" comprised both the sympathetic and the autonomic systems. Under the term "vegetative nervous system" were included all the fibres which went to the organs having smooth muscles, such as intestines, blood vessels, glands, ducts, and skin, as well as the nerve structures exerting a secretory influence upon glands; it also embraced certain organs with cross-striated muscles, such as the heart, the beginning and the end of the alimentary canal, and the muscles of the genital apparatus. Anastomoses were common among the nerve fibres of the vegetative system. This system also had a much more independent action, and it reacted to drugs in an altogether different manner; indeed, it was from the latter that so much had been learnt about it. A sort of balance seemed to be maintained between the autonomic and the sympathetic systems, so that one assumed an exaggerated action if the influence of the other were interfered with. Both systems were much affected by the secretions of various endocrine glands. Dr. Orr and he had demonstrated that changes could be produced both in the vegetative system

and in the central nervous system by placing a capsule containing pathogenic organisms in the neck, near the carotid artery, or in the abdominal cavity, and they suggested that the disturbances in this system were closely connected with the origin of the lesion in the central nervous system, a view which was supported by clinical evidence, instances of which were given.

Rebieloz.

ABYSSINIAN MEDICINE.

ABYSSINIA is a country virtually untouched by political, social, or scientific evolution; it remains as it was three thousand years ago, without any change beyond a superficial Christianity. The native lives a simple life in a healthy climate at an altitude of 3,000 metres. He is not the prey of alcohol, and is comparatively free from cancer and tuberculosis. His natural indolence makes him patient in illness, and this is an aid to recovery. He holds scientific medicine in contempt, and places his trust largely in amulets, charms, and superstitious rites. But he also has a traditional pharmacopoeia of his own. An interesting account of Ethiopian medicine is given by Dr. MÉRAB,¹ whose position as private physician to the Emperor of Abyssinia, Menelik II, and head of the dispensary installed in the palace at Addis Ababa, gave him ample opportunities of studying the peculiarities of the native constitution. The most common disease in Abyssinia is tapeworm (*Taenia saginata*). The favourite remedy is koussou, which has sufficient reputation as an anthelmintic in this country to be maintained in the *British Pharmacopoeia* 1914. Notwithstanding the severity of its purging action it is often taken at regular intervals by Abyssinians who are free from the worm. Unwelcome visitors are told that the master of the house has taken koussou, as a formula equivalent to "not at home." Butter which has become rancid from long keeping—it may be ten years or more—is next in favour, either alone or mixed with honey. This "medicated butter" is largely used as a remedy for all sorts of ailments, notably for malaria. Syphilis is common, but the disease is generally mild among natives, though it is very severe in Europeans who contract it from Abyssinian women. Arterio-sclerosis, gout, and rheumatism are rare. Mérab estimates that there are one or two lepers in every thousand of the population of Abyssinia, making a total of 20,000 in the whole country. No measures are taken to stamp out the disease. Bone-setting of a rough nature is largely used among some tribes, who have also a certain skill in eye surgery. Massage is used in cases of recently consolidated fractures, unreduced dislocations, sprains, contusions, and neuralgic pains. Bullets are said to be extracted with the aid of a fly called *Ouagimbit*, which is placed on the wound and kept there till, in four or five days, it has eaten its way through to the foreign body, which is then removed with forceps! In battle bleeding is stopped with fresh dog's dung and a tight bandage or with boiling oil. On the whole Mérab's testimony goes to show that the Abyssinian suffers from few diseases in any way peculiar to himself, and is enviable free from many which afflict more highly civilized peoples.

OBSTETRIC EMERGENCIES.

THE call for a second edition of *The Difficulties and Emergencies of Obstetric Practice*,² by Dr. COMYNS BERKELEY and Dr. VICTOR BONNEY, within two years of its appearance shows that the profession in general has shared the favourable opinion of it which we expressed in the review of the first edition. The only changes in the present volume are the addition of some illustrations and the supplementing of the letterpress in some points. The whole work has been thoroughly revised at the same time.

¹ *Médecine et Médecine en Éthiopie*. Par le Docteur Mérab. Paris: Vigot Frères. 1912. (Demy 8vo, pp. 218. Fr. 4.)
² *The Difficulties and Emergencies of Obstetric Practice*. By C. Berkeley, M.A., M.D., M.C. Cantab., F.R.C.P. Lond., M.R.C.S. Eng., and V. Bonney, M.B., M.D., B.Sc. Lond., F.R.C.S. Eng., M.R.C.P. Lond. Second edition. London: J. and A. Churchill. 1915. (Roy. 8vo, pp. 818; 302 figures. 24s. net.)

To those who are unacquainted with it the book may be cordially recommended as an entirely practical work of reference. The authors have been careful never to lose sight of the aim of the book as expressed in the title, and have scrupulously avoided making it anything of a textbook. The arrangement and printing are excellent, the index is full and exact, and the numerous illustrations combine as much scientific accuracy as is compatible with the almost diagrammatic clearness essential in a work of the kind. The result is that the busy practitioner who wishes to refresh his knowledge or to receive guidance on any difficulty or emergency likely (or unlikely) to be met with in his obstetric practice may do so with the minimum of trouble and a maximum of profit.

HANDBOOKS OF MEDICINE.

DR. WILSON's admirable *Handbook of Medical Diagnosis*,³ first issued in 1909, is now in its fourth edition—a fact that may be taken as proof of the practical merits of the book. It is divided into four parts. The first and shortest of these is on medical diagnosis in general. The second, 350 pages in length, describes the methods of physical examination and laboratory procedures useful in diagnosis. The third, on symptoms and signs, is rather shorter, and gives an account of the ways in which diseases of the various systems of the body should be investigated. The fourth part, 800 pages in length, is to all intents and purposes a textbook of medicine from which all descriptions of treatment have been omitted. Thus it appears that this *Handbook* covers the ground usually occupied by two volumes—one on methods of diagnosis, the other on medicine in general, barring treatment. The text is clearly written, and errs perhaps on the side of undue fullness; it would be more impressive and convincing if the sentences and paragraphs could be made shorter. The matter of the text attains a high level of excellence, and seems well up to date. It is satisfactory to note that Dr. Wilson recognizes Poynton and Paine's *Diplococcus rheumaticus* as the cause of rheumatic fever; this recognition has long been delayed in America. We are not sure that we agree with the author in his estimate (p. 179) of the frequency with which double aortic disease (stenosis and reflux) occurs, as compared with the frequency of the double aortic ("to-and-fro") murmur. No reference to Graham Steel's diastolic murmur of relative pulmonary incompetence seems to be made, although the murmur is not rare in cases of well-marked mitral disease with considerable hypertrophy of the right ventricle. The book would gain if the magnifications of the figures of microscopic appearances were always inserted, so that the student could form some estimate of the real size of the objects depicted. These, however, are but unimportant defects in what is an excellent manual for advanced students and practitioners of medicine, and may be warmly recommended to such readers.

The fifth edition of *Wheeler's Handbook of Medicine*,⁴ edited by Dr. W. R. JACK, has been revised, added to, and brought up to date. It gives a brief and workmanlike account of the subject in the condensed and tabulated form that is believed to be appreciated by medical students. It contains a great deal of useful information for examinees, and a fair amount of space is given to treatment. Like all books of its class it appeals to the memory rather than the intelligence.

BIOLOGY.

PROFESSOR CALKINS has produced a work on *Biology*⁵ which should be read by medical students early in their careers. It does not attempt to cover the ground of any English examination; it is valuable because it is a sound introduction to the principles of biology and the essential results of modern thought and experimental work. Various

³ *A Handbook of Medical Diagnosis*. In Four Parts: I, Medical Diagnosis in General; II, The Methods and Their Immediate Results; III, Symptoms and Signs; IV, The Clinical Application. For the Use of Practitioners and Students. By J. C. Wilson, A.M., M.D. Philadelphia and London: J. B. Lippincott Co. 1915. (Med. 8vo, pp. 1463; 14 plates, 408 figures. 25s. net.)

⁴ *Wheeler's Handbook of Medicine*. By W. R. Jack, B.Sc., M.D., F.R.F.P.S.G. Fifth edition. Edinburgh: E. and S. Livingstone. 1916. (Cr. 8vo, pp. 566. 8s. net.)

⁵ *Biology*. By G. N. Calkins, Professor of Protozoology in Columbia University. New York: H. Holt and Co.; London: G. Bell and Sons, Ltd. 1915. (Demy 8vo, pp. 249; 101 figures. 7s. 6d. net.)

types of invertebrate animals and one or two plants are described, not always exhaustively, but rather as illustrations of some general principle of biology. Thus, in the description of the anatomy of the earthworm, emphasis is laid on the nervous system, the significance of the neurone, and of a reflex arc. Again, the chapter on classification and the phyletic significance of homologous organs leads on to a description of the lobster, a well-chosen example of serial homology. It is natural that Professor Calkins should explain the conjugation and division of *Paramecium* in terms of the cell theory, the individual, and sex, but it should not be forgotten that an increasing number of biologists oppose him in this, and refuse to describe these phenomena as sexual, regarding the protozoa as non-cellular rather than unicellular. Professor Calkins has the valuable gift of explaining matters of theory clearly to the unlearned, and within this short volume he introduces his pupils to all that is of highest importance in the principles of zoology, botany, and physiology; his subjects range from the differentiation of cells and tissues, the action of crystalloids, and the effect of enzymes on protoplasm, to parasitism, immunity, and the Mendelian theory of heredity. The index is adequate and the stereographic drawings of internal anatomy are excellent.

Dr. CHARNOCK BRADLEY'S *Structure of the Fowl*⁶ deals with its subject quite accurately, system by system, but we do not understand for what class of student it was written. Some of the common stumbling-blocks, the disposition of the peritoneum and the nature of the coelom, for instance, are slurred over, while other matters are discussed in a manner suited to a student who has not yet mastered the anatomy of the much-dissected frog. It is a pity, too, that an occasional word is not given to the physiology of the parts described; we notice, for instance, that when the author describes the anatomy of the syrinx he makes no mention of the fact that it is the bird's organ of voice. The author does not always express his meaning with clarity, and in a few cases is definitely careless—for example, in his use of "cranial" for "anterior," or, as the Americans would say, "cephalad." The chapter devoted to the embryology of the fowl is one of the most successful in the book, and the subject is by no means an easy one to summarize. It would perhaps have been better to say either a little more or a little less about the organogenesis of the urinogenital system, and the pro-, meso-, and meta-nephroi and their ducts. The figures are good, and the diagrams of sections, histological and embryological, are an unusual but not unsuccessful feature of the book; if a fault must be found, it is that they are a little too simple; some of the cells lack walls, others nuclei. The book has an adequate index.

The *Textbook of Economic Zoology*,⁷ by KELLOGG and DOANE, gives a broad outline of the whole animal kingdom, introducing the student first to a few types, the amoeba, the frog, and others, and then to each phylum in systematic sequence. Special attention is given to parasites and species of economic importance; the second part of the book is mainly devoted to insects which carry disease, or attack the orchard, the crops, or "garden truck." Short outlines are also given of some of the methods usually employed in controlling insect pests. All this information appears to be reliable, but the book undoubtedly suffers from a fault which is common to many elementary textbooks. Too much ground is covered; its educational value would have been greatly enhanced if the authors had been content to omit some of the smaller phyla and given more space to selection, variation, heredity, parasitism, and other general topics, some of which are discussed so shortly that they will hardly interest the elementary student, to whom the book is addressed. The illustrations, taken mainly from common American animals, are excellent, and the authors evidently desire to make their pupils study in the field, and think for themselves. Those parts of the book which are devoted to the pathogenic protozoa and the transmission of disease by insects are

rather uneven; for instance, the majority of the trypanosome diseases of domestic animals are mentioned, but there is no reference to the fact that lice carry typhus. As the field which this excellent manual covers is so wide, its value would have been greater if a select bibliography had been appended to it.

Under the title of *Modern Problems of Biology*⁸ Professor MINOT of Harvard University has published a very interesting course of lectures delivered by invitation of the Grand Duke of Saxe-Weimar at Jena, in December of 1912. The lectures were given before a mixed audience, a fact which must have added considerably to the difficulty of explaining so clearly the results of the latest research into the most intricate problems of biology. Special prominence is given to the work of American investigators, in view of the probability that such work would be less known in a foreign country than that of its own men of science. An introductory chapter deals with "the new cell doctrine," identifying as the chief problem of biology the investigation of the structure and composition not of cells as such, but of the living substance of which they are composed. The second lecture deals with cytomorphosis, the foundation of morphology, and its four stages—the undifferentiated or embryonic, the differentiated, the degenerative, and the culmination of this last in death. In the two succeeding lectures facts are adduced in support of the natural immortality of unicellular organisms, death being, in the author's opinion, the price paid by multicellular organisms for that higher form of existence which they owe to co-operative differentiation. The question of the function of conjugation is raised, the author citing the observations of H. S. Jennings as to the increased variability of *paramecium* after conjugation, as compared with ordinary division. On this view sexual reproduction may be conceived as a modified form of conjugation, as it also favours variability. In a chapter dealing with the determination of sex, an account is given of the important discovery by Professor C. E. McClung of the part taken by the accessory chromosomes in the sexual cells of certain insects. In the second division of the spermatocytes the accessory chromosomes each pass undivided into one of the daughter cells. Thus there are produced two distinct forms of spermatozoa, and, contrary to McClung's first conclusion, it has been demonstrated by E. B. Wilson that those which contain an accessory chromosome determine the formation of females. In his last lecture Professor Minot, dealing with the conception of life, expresses the conviction that the phylogenesis of vertebrates is dominated by the evolution of consciousness. Consciousness he regards not as a form of energy but as a something *sui generis*, revealing itself by the transformations of energy which in some unknown way it brings about.

NOTES ON BOOKS.

THE handbook, *Alcohol and the Human Body*,⁹ by Sir VICTOR HORSLEY and Dr. MARY STURGE, has now reached its fifth edition. It is issued at a price which places it within the reach of all. The case against alcohol could not be put more forcibly and fully than in these pages. The attitude assumed is very uncompromising, as may be judged from the statement on page 326, that "what is commonly described as moderate drinking has a most injurious influence on health and life."

The third part of Mr. JACKSON CLARKE'S book on *Protozoa and Disease* came out in 1912. The fourth part has now been published, under the title *Rhizopod Protozoa*.¹⁰ The author now finds himself in a position definitely to affirm that the protozoa he finds to be the cause of such diseases as cystic ureteritis, molluscum contagiosum, and cancer are in truth protozoa akin to

⁶ *Modern Problems of Biology*. By C. S. Minot, LL.D., D.Sc. Oxf. Philadelphia: P. Blakiston's Son and Co. 1913. (Demy 8vo, pp. 132; 53 figures. 1.25 dols. net.)

⁹ *Alcohol and the Human Body*. By Sir V. Horsley, F.R.S., F.R.C.S., M.B., B.S. Lond., Hon. M.D. Halle, etc., Major R.A.M.C., and Mary D. Sturge, M.D. Lond.; with a chapter by A. Newsholme, C.B., M.D., F.R.C.P., D.P.H., and a chapter written in collaboration with Sir L. Rogers, K.C.I.E., Lieutenant-Colonel I.M.S., M.D., F.R.C.S., etc. Fifth edition, enlarged. London: Macmillan and Co., Ltd. 1915. (Cup. 8vo, pp. 367; 39 figures. 1s. net.)

¹⁰ *Rhizopod Protozoa: The Cause of Cancer and other Diseases*, being Part IV of *Protozoa and Disease*. By J. Jackson Clarke, M.B. Lond., F.R.C.S. London: Baillière, Tindall, and Cox. 1915. (Cup. 4to, pp. 101; 67 figures. 7s. 6d. net.)

⁷ *The Structure of the Fowl*. By O. C. Bradley, M.D., D.Sc., M.R.C.V.S. The Edinburgh Medical Series. London: A. and C. Black. 1915. (Cr. 8vo, pp. 164; 75 figures. 3s. 6d. net.)

⁸ *Elementary Textbook of Economic Zoology and Entomology*. By V. L. Kellogg and R. W. Doane. London: Constable and Co., Limited. 1915. (Cr. 8vo, pp. 542; 245 figures. 6s. 6d. net.)

mycetoza. He holds that our imperial attack on the cancer problem has been a failure. His book is excellently illustrated; the problems with which it is concerned are largely matters for microbiologists and microscopists to decide, for they turn on the interpretation of microscopical appearances, a subject on which opinions are notoriously likely to differ.

A Manual for Midwives,¹¹ by Drs. C. N. LONGRIDGE and J. B. BANNISTER, is a practical book written in clear language, and with the essential points printed in strong type so that they cannot be easily overlooked. That the book has already reached a second edition proves that it has met a real want. We are inclined to think that the frontispiece, excellent though it is, may be a little confusing to some of the readers, as it shows the head of the fetus in the upper part of the fundus uteri. An illustration in so prominent a place is seen before the text is read, and may lead a beginner to think that this is the normal position of the fetus *in utero*. We feel that in all manuals for midwives every possible element of confused thought should be avoided.

Chestnut pudding on the dinner table is all very well and is in its place, but such chestnut pudding as Mr. GEOFFREY RHODES¹² offers us in literary form is neither appetizing nor digestible. His book *Mind Cures* is made up mainly of Early Victorian platitudes interspersed with anecdotes from John Abercrombie, W. B. Carpenter, Hack Tuke, and other worthies. If the anecdotes do not illustrate the thesis that Mr. Rhodes seeks to inculcate, that is not the fault of the anecdotes, many of which are quite good, or were, until they were worn out, but because it is not clear what thesis he desires to inculcate.

¹¹ *A Manual for Midwives*. By C. Nep an Longridge, M.D. Vict., F.R.C.S. Eng., M.R.C.P. Lond., and J. B. Bannister, M.A., M.D., B.C. Camb., M.R.C.P. Lond., F.R.C.S. Edin. Second edition. London: J. and A. Churchill 1915. (Cr. 8vo, pp. 339; illustrated. 3s. 6d. net.)

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the committee, held on May 9th, twenty cases were considered and £195 voted to fifteen of the applicants. The following is a summary of the cases:

L.S.A. Lond. who had practised at Hereford. Has now joined the R.A.M.C., and his inclusive pay is 18s. 6d. a day. He pays 17s. 6d. per week for a cottage. He gave up a practice worth £80 a year. Is married, and has one son, aged 16, at school at Dover, where the fees are £120. Applicant requires help to finish the education of his son. The boy has gained two scholarships worth £30, and if the Fund could provide £30 he could manage. His income is not sufficient to meet his expenses, which he puts down at—son £120, wife £100, self £100. Case sent by the Professional Classes War Relief Council. Voted £10 from the Emergency Fund and referred to the Guild.

Widow, aged 60, of L.R.C.S. Ire. who practised at Little Sutton and died in 1900. Applicant received about £25 per annum from property which was mortgaged, but owing to this being recalled, and the rate of interest on the new one increased and heavy repairs, it has taken the proceeds (£25). She has also taken in boarders, but recently has not been successful. Owing to this, the high price of food, and failing health, she finds herself in financial difficulties. Rent paid, £42 11s. per annum. Voted £10.

Widow, aged 56, of M.R.C.S. Eng. who practised at Bradworthy and died in 1908. Applicant has lost through bad investments all her late husband left. Has now lost her mental faculties. Has two daughters, aged 30 and 21, both governesses, who earn together £90, and one son, aged 26, single, an engineer with £160 per annum, and who provides a home for his mother, and the daughters give her £32 10s. Friends give £39. Referred to the Guild.

Widow, aged 70, of M.R.C.S. Eng. who practised at Liverpool and died in 1880. After the death of her husband she earned a living by taking in lodgers. One of her sons qualified as a medical man, and she kept house for him, but owing mainly to overwork through the war he died early this year, and all he left was an insurance of £250 which went to his mother. The applicant proposes to try and take lodgers again, but for the present has her son's house rent (£71 10s.) on her hands. Voted £10.

Widow, aged 57, of L.R.C.P. Edin. who practised at Blackburn and died in 1902. Used to earn a living by looking after children while their parents worked in the cotton mills, but owing to ill health has had to give this up. Has one daughter, aged 19, a shop assistant, who earns 15s. per week. This is their sole income apart from the fund. The Manchester Branch of the Guild speak well of this case and help a little. Previous relief, twice, £24. Voted £15 in twelve instalments.

Daughter, aged 69, of M.R.C.S. Eng. who practised at Cranbrook and died in 1890. Applicant is not very bright mentally,

and quite unable to work. She has an annuity from another charity, £30. She has to pay £1 per week for board and lodging, and as the landlady with whom she lived has just died she may have to pay more. She is a difficult person to get on with. Previous relief, five times, £60. Voted £12 in twelve instalments.

Daughter, aged 54, of M.R.C.S. Eng., L.R.C.P. Dublin, who practised at Rickmansworth and died in 1901. Applicant was left quite unprovided for, and suffers from arthritis and fibrosis, etc. Only income £39 from a relative. Pays £13 for rent of one room. Relieved three times, £30. Voted £10 in two instalments, and referred to the Guild.

Widow, aged 62, of M.D., Ch. McGill, who practised at Waterloo, Liverpool, and died in 1914. Owing to the very long illness of her late husband he was unable to provide for his family. There are five children, aged 30 to 38. The two sons are abroad and unable to help, and of the daughters, one is suffering from tuberculous kidney, another is dyspeptic, and the eldest is the only wage earner, and has £91 per year; £29 paid in rent. Relieved once, £18. Voted £18 in twelve instalments, and referred to the Guild.

Daughter, aged 69, of L.S.A. Lond. who practised at Christchurch and died in 1880. Has a life interest in an old house at Christchurch, but owing to increasing expenses does not benefit from it. Lived with a sister, recently dead, who had an artist's pension of £50, which went into the general fund. Applicant earns a little as an artist, but finds it very difficult to obtain commissions at present, and her eyesight is failing. Relieved once, £18. Voted £18 in twelve instalments.

Daughter, aged 44, of M.D. Aberd. who practised at Glasgow and in Australia and died in 1891. Applicant was without any means, and trained as a masseuse, and was able to earn her own living until her health became impaired two years ago, and was then only able to take occasional work. Has recently had diphtheria, and is now recovering, and hopes to work again soon. Relieved twice, £20; last 1914, £10. Voted £10.

Daughter, aged 60, of M.R.C.S. Eng. who practised at Blackheath and died in 1880. Applicant mentally deficient, and has to be provided for by a sister who has an interest in a girls' school, and has a difficulty in making ends meet, and the help previously given has been greatly appreciated. Strongly recommended by the Guild. Relieved eight times, £69; last £10, April 2nd, 1915. Voted £10 in two instalments.

Widow, aged 40, of L.R.C.P. and S. Edin. who practised at Clifton, co. Sligo, and died in 1912. After her husband's death applicant opened a sweet shop in Edinburgh, and managed to get on until she had to undergo an operation in May, 1915. The Fund then made her a grant of £10. In April, 1916, her shop was blown up by a bomb from a Zeppelin, and all her stock and furniture destroyed, and she was not insured. Now wants help to re-establish herself. Postponed for further inquiries.

Daughter, aged 61, of L.S.A. Lond. who practised at Cheadle and died in 1874. Was left totally unprovided for, and, owing to ill health, has never been able to undertake permanent work. Earns a few pounds a year by sewing, and a friend provides £25 per year. Rent 4s. 9d. per week. Relieved ten times, £88; last £12 12s., May, 1915. Voted £12 in twelve instalments.

Daughter, aged 65, of M.D. St. Andrews who practised at Dover and died in 1881. Has endeavoured to earn a living by conducting a servants' agency, but during the last two years, and especially since the war, has been very unsuccessful. She has also been in the habit of taking in some boarders, but these have ceased. Relieved twice, £20; last £10, May, 1915. Voted £10.

Widow, aged 49, of L.S.A. Lond. who practised at Leyton and died in 1914. Was left without any means with five young daughters. On the death of her husband it was discovered that the practice was much involved, and had to be sold to pay the creditors. Her brother, a medical man, bought the practice with a view of helping his sister and her children, but owing to the high salary that had to be paid to a locum, and the increased cost of drugs, the practice was not paying. Help wanted towards the education of the children. Previous relief, three times, £25. Voted £10.

M.R.C.S. Eng., married, and who had practised at Manchester and London. Owing to ill health unable to earn anything, and has lost all his savings. Only income an old age pension. Relieved twice, £19 10s. Voted £18 in twelve instalments, and referred to the Guild.

Wife, aged 50, deserted by her husband, who is an M.R.C.S. Eng. Has no means, and is a chronic invalid. Has one daughter, aged 22, who nurses her mother, and has a few day-school pupils, from whom she receives 6s. 6d. per week, of which 5s. has to be paid in rent. Relieved three times, £36. Voted £12 in twelve instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

British Medical Journal.

SATURDAY, MAY 27TH, 1916.

THE ENROLMENT SCHEME AND THE MILITARY SERVICE ACT.

THE Military Service Bill, when it left the House of Commons last week, contained no provision for dealing with the special circumstances attending the recruitment of medical officers for the army. In the House of Lords a new clause was introduced into the bill by the Government spokesman, Lord Sandhurst, at the instance of the Army Council. In the House of Commons it was carried, after a division, by 163 to 42. It forms part of the scheme of the Army Council for obtaining doctors for the army. They are needed to serve as doctors with commissions in the R.A.M.C. and not as ordinary combatants. The clause provides means whereby medical officers needed for service in the army may be selected with due regard to each of three considerations—the needs of the medical services of the forces; the medical needs of the civil population; and the financial and other circumstances of the individual doctor. The necessary adjustments can only be effected by a body which, in the first place, can make arrangements for carrying on the work for the civil population of the man selected to accept a commission in the medical service; which, in the second place, has local knowledge at its disposal; and which, in the third place, is capable of considering the problem as it arises in the different areas, from a central standpoint and on a comparative basis. The local tribunals under the Act are obviously not bodies capable of adjusting the matter, for they can only consider each case from its strictly individual and local aspects, and can do nothing in the way of providing for the carrying on of the work of the doctor who joins the medical service of the army or navy. Nor are they in a position to discover the real facts as to his position. They will not, for instance, know whether arrangements can be made for his work to be done by neighbouring colleagues, or for part of the income from that work to be secured for him or his wife during his absence. A local tribunal, being unable to judge whether a doctor could be spared without grave injury to the civil needs or without involving him in undue financial hardship, might therefore decide to exempt a doctor who could really be spared, with the result that some other practitioner would be taken whose departure would be seriously injurious to the medical needs of the civil population, or to whom the personal hardship would be much greater.

The new clause provides "for the establishment of professional committees to deal with claims for exemption made by duly qualified medical practitioners," and directs that any application made by a medical practitioner on any ground other than that of conscientious objection shall be referred by the tribunal to the appropriate professional committee, and that the recommendation of this committee shall be binding on any tribunal. The necessary machinery already exists in the professional committees which, at the request of the War Office, have been for some time past organizing the medical profession for war

purposes. The enrolment scheme which they have established is designed to enable the medical services of the navy and army to obtain the medical men they need and to ensure that the medical officers shall be selected in a manner to avoid needless injury to the medical requirements of the civil population, while having regard to the individual doctor's circumstances.

As readers of this JOURNAL are very well aware, enrolment under the scheme means that the enrolled doctor gives an undertaking to accept a commission in the Royal Army Medical Corps or, if he prefers, in the Royal Naval Medical Service if and when he is offered one. Though a large proportion of the doctors of military age and capacity have accepted this obligation, there is still a substantial number who have not done so. The reasons for this abstention no doubt vary in individual cases, but it is believed that the total number has been considerably affected by the possibility of resort to the local tribunals in the expectation of obtaining exemption from service, or the offer of service.

It is believed that the clause will also influence the decision of doctors between 41 and 45, who, though not within the compulsion of the Military Service Act, are eligible for commissions in the R.A.M.C. As is well known, a considerable number of men between these ages, both single and married, have already enrolled, but some have made the not unnatural condition that their offer of service should be contingent on the younger men being selected first. Evidence, in fact, has been afforded during the last few months that medical men between 41 and 45 may be deterred from enrolling by the apprehension that younger and perhaps unmarried members of the profession in the district may obtain exemption from the local tribunals. It is stated that some have in certain districts already done so, to the detriment of the enrolment scheme. It is clearly of great importance to secure as large an enrolment list as possible, since the wider the field of selection the better can the medical needs of the army be met, and the smaller will be the risk of endangering the civil needs in any area, or inflicting avoidable hardship on individual practitioners.

The only professional committees in England and Wales which possess the knowledge required to formulate recommendations to tribunals are the Central Medical War Committee and the reference committee appointed by the Royal Colleges of Physicians and Surgeons for the special consideration of the consultant and teaching staffs of the metropolitan hospitals. In Scotland the body corresponding to these is the Scottish Medical Service Emergency Committee. These two committees have been working for the War Office for nearly a year, and also for the Central Tribunal, of which Lord Sydenham is chairman, established under the principal Act (the first Military Service Act, 1916). The work of the Scottish Medical Service Emergency Committee is very thoroughly organized, and it has obtained accurate information with regard to all localities in Scotland. In England and Wales the Central Medical War Committee has the assistance of local Medical War Committees established in all parts of the country, from which it has obtained and can continue to obtain full and accurate information.

We learn that the War Office has decided to recognize, under the regulations to be made in fulfilment of the new clause, these three existing professional committees—namely, the Central Medical War Committee, and the reference committee of the Royal Colleges, for England and Wales, and the Scottish

Medical Service Emergency Committee for Scotland. We are informed that an Order in Council to this effect will be issued at once.

Thus, under the new clause, any application by a medical man to a tribunal for exemption from military service on any ground other than that of conscientious objection will be referred to the appropriate professional committee, and its decision will be final and binding on tribunals under the Act.

In its practical working, however, the new clause will apply only to those medical men who have not taken the precaution of enrolling, or do not enrol within such time as may still be available, either with the Central Medical War Committee for England and Wales (429, Strand) or the Scottish Medical Service Emergency Committee (at the Royal College of Physicians, Edinburgh).

Under the instructions issued by the Army Council the enrolled man is not to be called up by the recruiting department; if, by inadvertence, an enrolled man is so called up, it will be sufficient for him to produce his certificate of enrolment to stop all proceedings. The unenrolled man will have to go through a more roundabout process. He will have to apply for exemption to the tribunal under the Act, which will be bound to refer the matter to the professional committee—that is to say, his case will, in the end, go before the same professional committee as it would go before directly were he enrolled, and, as has been said, the recommendation of the professional committee is binding on any tribunal constituted under the Military Service Acts.

THE MORTALITY AMONG EDUCATED INDIANS.

UNDOUBTEDLY the death-rate in India, judged by the better of the European standards, is unduly high. More than 90 per cent. of the Indian population lives and dies without any adequate sanitary care or control; in 1911 more than four million of the inhabitants of India died of preventable fevers, malaria accounting for at least a million deaths; of the sixty-four largest towns in India, seven have an annual death-rate exceeding 70 per 1,000, and in only twenty-five was the rate below 30; in England the death-rate is now below 15. The Indian male at birth has an expectation of less than twenty-three years of life, whereas the Englishman's expectation of life is over forty-six years. In England the annual death-rate is lower in the upper classes than it is among the proletariat; in India, contrariwise, the educated classes have an even higher death-rate than the uneducated and poorer masses.

The chief conditions that prejudicially affect the health of the inhabitants of India have recently been subjected to a searching analysis¹ by Lieutenant-Colonel Prasad, I.M.S.(ret.), more particularly as they affect the educated classes of the population. Any one, he says, who is acquainted with modern India and has been in the country for any length of time, must have been struck by the frequency of premature and sudden death among young Indians of the well-to-do and educated classes. His essay is based on the recently collected experiences and opinions of the chief Indian medical and lay authorities who may have had occasion to consider the matter in its various bearings. Dr. Prasad is himself a Hindu and has worked as a medical officer

for many years in India, and so is able to write with authority upon this very complicated question. The high mortality he connects exclusively with the lack of adequate hygiene, using the term in its widest sense, that is still inevitable in the lives of almost all the inhabitants of India.

He illustrates this lack of hygiene by considering in turn all the various departments of Indian life and up-bringing. In the case of marriage, he notes that 98 per cent. of Indian girls are married before they reach the age of 15; the bridegroom is likely to be of much the same age. But in the upper classes a man can hardly complete his education before he is 25. Dr. Prasad would therefore have him defer marriage until about this age; yet if a boy remains unmarried until he has passed all his examinations, parents argue that they will not be able to secure for him a girl of good family, as no one wishes to give a girl of 15 to a man of 25. None the less, the common early marriages are, he holds, ruinous to the health of the contracting parties and are the chief cause of the terribly high mortality among the first children born to these youthful parents. Dr. Prasad points out that there is crying need for improvement in the sanitation of Indian towns and dwelling houses, in respect particularly to the supply of fresh air and good potable water. He holds that the average Indian diet is too nearly vegetarian and that it is lacking in protein, with the result that diabetes mellitus is of common occurrence. Here he enters upon a question that is nowadays widely discussed in India, and still far from settled. He is in favour of increasing the number and improving the quality of the games used for exercise, and gives a number of admirable instructions in personal hygiene that deserve general adoption.

The essay contains many severe comments on the low position of women, the lack of training and education in the all-important duties of motherhood, the survival of the *purdah* system, as well as on the deplorable effect of the system of early marriage. In Bombay the infantile mortality for the first year of life varies between 379 and 419 per 1,000, and it stands at 213 for the whole of India; in Norway, Sweden, and Hampstead, according to Dr. Prasad, it is only 50 per 1,000, but it is not quite fair to take the very special population of that suburb as a standard of comparison for the great population which includes all ranks and occupations.

He has much to say as to the changes that seem necessary in the education of Indian children, and in the local schools and colleges; only five in a thousand Indian women, it is said, can read and write.

The final conclusion to which he comes is this—that sanitation is the crying need in India at the present moment. He hopes to see the sanitary administration of the country put upon the same governmental basis as the departments of Public Works and Education, and extended downwards until it comes into touch with a proper staff of sanitary labourers in every town and village. As he says, sanitation "is the ultimate basis of all prosperity, and should be the first plank in the platform of every scientific and civilized government." He is inclined, perhaps, to make light of the difficulties and inertia that must impede the progress of modern improvements in a conservative population, but his essay is worthy of full consideration by those who have to deal with the problems raised, and is written by one who has the advantage of a full knowledge of the special obstacles that will have to be met and overcome if the high death-rate among Indians of all castes and classes is to be lowered.

¹ *Health and Mortality amongst Educated Indians*. By K. Prasad, M.D. Edin., Lieutenant-Colonel I.M.S. (retired). Bahadurganj, Allahabad: The Panini Office. 1915. (Med. 8vo, pp. 178, Rs.2.8.)

THE CHEMICAL TREATMENT OF CEREBRO-SPINAL MENINGITIS.

It is notorious that the curative treatment of cerebro-spinal meningitis is at present very unsatisfactory. In certain hands the use of antimeningococcal serum has proved satisfactory up to a certain point; many, however, of the practitioners who had to deal with epidemics of the disease in this country in 1915 came to the conclusion that treatment by repeated lumbar puncture was as good as treatment by lumbar puncture combined with the injection of antimeningococcal serum. Perhaps the serums available were not homologous with the types or strains of meningococci that were being met with. The possibilities of the treatment of the disease by intrathecal injections of chemical antiseptic drugs have recently been brought once more to the front in America. In 1902 Seager reported very favourably on the use of lysol in this way, on the strength of his experience of an epidemic of cerebro-spinal fever at Lisbon. The first results were not confirmed by later observations, and the treatment was dropped. Subsequently protargol was employed in the same way, in place of lysol. Drs. Flexner and Amoss¹ have studied the effects of these drugs in the treatment of experimental infections in monkeys and young guinea-pigs with meningococci. Neither protargol nor lysol proved to have any curative action on the experimental peritoneal infection of young guinea-pigs with young cultures of the meningococcus, and protargol was without curative action in subarachnoid meningococcal infections in the monkey. On the contrary, these authors point out that both drugs are antileucocytic and antiphagocytic in their influence on the leucocytes, and are potent protoplasmic poisons. Recovery from meningococcal infections in both man and experimental animals is accomplished chiefly through the process of phagocytosis. The specific antiserum acts curatively by increasing the emigration of leucocytes, by directly promoting phagocytosis, by agglutinating the meningococci, and also by neutralizing the bacterial endotoxin; lysol and protargol have none of these actions to their credit. Hence, whatever the theoretical bactericidal advantages drugs possess, it is more than offset by the harmful effects they cause. What is wanted in the treatment of cerebro-spinal meningitis is an antiserum that represents the several types and many strains of meningococci. The authors say that this problem is now in a fair way to being solved; there is nothing to show that treatment by chemicals or antiseptics has any future before it.

RESULTS OF SANATORIUM TREATMENT.

In a somewhat belated report the Council of King Edward VII Sanatorium at Midhurst present the account of their stewardship for the twelve eventful months ending July, 1915. Disturbed in the even course of its work by the requirements of the War Office, the sanatorium made provision for consumptive soldiers during the early months of 1915, but since the assumption of responsibility by the Insurance Commissioners during the month of June, 1915, the normal routine has been resumed. The absence of the first assistant medical officer and of the pathologist on military duty has necessitated the curtailment of some of the pathological and research work, and no reference to it appears in the report. The results of the treatment of 352 patients are recorded, and these include 94 military patients. The use of tuberculin was discontinued at the end of the year 1914. It had been employed in treatment for three complete years, and a long time must now elapse before its effect can be estimated with any certainty. Thus far it has not been shown to increase the efficiency of sanatorium treatment to any appreciable extent. In the tables of results the details of cases in which the

presence of tubercle bacilli were demonstrated are kept separate from those in which they were not. Every effort would appear to have been made to follow up the after-history of cases discharged, and the tables showing the number of patients alive for each successive year after discharge, with and without bacilli, are highly instructive. Of 1,461 patients discharged (with bacilli) in eight years, 714 were dead, 608 still living, and 139 lost sight of, while of those without demonstrable bacilli only 47 out of a total of 369 were dead, 271 still living and 51 lost sight of. These figures point once more with great force to the paramount need for treatment of the disease before the process of destruction has begun and the escape of bacilli rendered possible. Until this great lesson has been thoroughly instilled into the public mind, the relative success of sanatorium treatment will continue to be very far below the level at which it aims.

THE PROBLEM OF INSTINCT.

To what extent is the view still prevalent among biologists that instinct is a rudimentary form of the function which culminates in reason justifiable? Professor Bergson, a pioneer critic and opponent of this interpretation, regards it as a legacy from the doctrine of Aristotle, who saw in vegetative, instinctive and rational life three successive degrees of one and the same tendency, whereas they are, in his own opinion, "three divergent directions of an activity that has split up as it grew," the difference between them being one of kind, not merely of degree. The fact that we may all agree in regarding man as the masterpiece of Nature hardly justifies the conclusion that all organisms are to be appraised in terms of their approximation to the human type. Evolution is too vast and multiform a process to be fitly compressed within the conception of a linear process; there is much to be said for Bergson's contention that in the plant, the animal and man life reveals itself as a trichotomy, branching off at its outset in three main directions, and further subdividing in pursuit of many diverse goals. In Mr. N. C. Macnamara's *Instinct and Intelligence*, recently reviewed in these columns, the traditional view of instinct as a stage on the ascent towards reason is tacitly assumed, and the capacity for intelligent behaviour shown to increase with every advance towards the higher complexity and specific mechanism of the nervous system characteristic of man. This view is, we gather, endorsed by Colonel Kenneth Macleod in an able paper on *Instinct and Reason*, contributed to the April number of the *Caledonian Medical Journal*. Colonel Macleod even stigmatizes as a fallacious abstraction "the radical distinction commonly postulated between instinct and reason." Bergson's contention is that neither instinct nor reason are met with in experience in their purity, and that there is always an element of rationality in "instinct," of instinct in "reason," and we are inclined to support the author of *L'Évolution Créatrice* in making the distinction one of kind, not degree. If a generalization might be ventured, it would be that the typical instinctive act finds the means through the end, the typical rational act the end through the means. It is questionable whether the definition as "instinctive" of actions intelligently learned and become by force of habit automatic, may not have prejudiced the issue, for many truly instinctive actions reveal an almost transcendent precision and complexity, and yet cannot be ascribed, either from an evolutionary point of view or from that of immediate inception, to intelligence as commonly understood. Nor is it easy to believe that the power of instinctive reaction in its higher and more complex manifestations can have been built up piece-meal out of tentative reactions, under the sole guidance of natural selection. Even if it be admitted with Colonel Macleod that in a general way and in the human organism "certain portions of the nervous tissue subserve certain functions; the most

¹ S. Flexner and H. L. Amoss, *Journ. Experim. Med.*, Baltimore, 1916, xliii, 683.

distal elements simple reflex acts, intermediate parts, such as the basal ganglia, instinctive adjustments, and the cerebral lobes ratiocination," a caveat must be entered against the assumption that instinct is in itself and in its own sphere nothing more than we find it in ourselves. For there are good grounds for suspecting that we have developed reason not by the perfection but at the expense of instinct. And that being so, the elucidation of the problem of instinct should be sought not so much by the study of man, or of the higher mammalia as by that of organisms in which its guidance is, if not *unmixed*, at any rate predominant.

FOOD AND DRINK.

We have received a copy of the *True Temperance Annual*, 1916, issued by the True Temperance Association, Caxton House, Westminster, S.W. We know nothing about the association beyond what is to be gathered from this annual, but it would appear to be inspired by the same motives as the Public House Trust Company. Its two chief aims are "to create a healthy and reasonable public opinion on the subject of temperance in drinking," and to encourage the development of the public house into a place adapted to the social needs of the people, which to-day it is not. The community contains a certain proportion of persons who are so unfortunately constituted that, if they drink alcohol at all, they cannot resist the temptation to drink too much; there are those also who enjoy getting drunk, and set out on a holiday with the deliberate intention of returning home drunk. At the other end of the scale are persons so impressed by the evils arising from the use of alcoholic beverages that they would stop their sale altogether. Between these two extremes there is a very large number of persons who are in the habit of taking alcoholic beverages with meals, and who, judging from their own personal experience and observation, do not consider total abstinence necessary for themselves or total prohibition a sound national policy. But they hold, or the majority of them hold, that the ordinary public-house with its stand-up bar—a mere drinking place—is a national evil. Their view has been well stated by the Bishop of Birmingham when he said, in a diocesan address last November, that the remedy for drunkenness in this country lay very greatly with the improvement of the public-house itself, and that in countries where food and non-alcoholic drinks had the same attention paid to them in the public hosteleries as alcoholic drinks there was less likelihood of over-drinking. This opinion seems to be confirmed by the experience of France, where there has been a serious decay of the "café habit" and a growth of drinking bars, with a corresponding increase of the number of alcoholics. The evil and its remedy were recently discussed very fully by the Académie de Médecine, which reported in favour of stopping the sale of spirituous liquors containing over 50 per cent. of alcohol and of imposing a supertax on all drinks containing more than 15 per cent. of alcohol. Two or three members objected to the issue of a wine ration to French soldiers, but this was not approved by the large majority, and the ration is still being issued, though the sale of spirits is subject to severe restrictions. Cardinal Bourne, last February, said that in this country we needed, to take the place of public-houses, institutions providing recreation and the equivalent of home comfort. If by the last phrase food is intended to be included then the views of bishop and cardinal appear to be very nearly identical. The Central Control Board (Liquor Traffic) seems to hold a very similar opinion, for its first report contained the following paragraph: "The Board, however, attach very considerable importance to the constructive side of their work, and this side has received their careful consideration. The Board incline to the view that excessive drinking may often be traced to the want of adequate facilities for food, refreshment, and recreation, particularly in conjunction with long hours and overtime. The improvement of

public-houses and the provision of canteens may therefore do much to render less necessary the imposition of purely restrictive measures. The Board are accordingly encouraging by all the means in their power the efforts which are being made, whether by employers or by public-spirited voluntary societies or by other bodies interested, to improve the conditions under which adequate facilities for food and drink can be secured in munition and transport areas." The policy here outlined is one which could be applied everywhere, and, to put the matter on the lowest ground, we believe that there are not wanting abundant signs that the licensed trade will find it to its interest to abandon its present attitude. The evil of drunkenness and the failure of dealers to do anything to mitigate it have so impressed themselves on the minds of the people of Canada that total prohibition is now in force in many States, and will, it is thought, before long apply to the whole Dominion. Another sign of the times is that the Central Control Board has, at the request of the naval authorities, made an order prohibiting entirely the sale of spirits in the western parts of Inverness-shire, Ross-shire, Cromartys-shire, Skye, and all the outer islands from Lewis to Barra.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.¹

THE greater part of the current section of the *New English Dictionary* is the work of the late Sir James Murray, the remainder having been completed by the Scriptorium staff, with editorial revision by Dr. W. A. Craigie. The part of the alphabetic rubrics included in it runs from *turnadun* to *tzirid*, neither of them familiar words. A *turnadun* is a bull-roarer or rhombus, and a *tzirid* a jerid or wooden javelin. It is only when the last few pages of this section are reached that medical terms appear in any profusion. This is to be explained by the fact that in them only do words derived from the Greek make a show. They all begin with *ty*, and they come from *τύλος*, a knob, or *τύλη*, callus; from *τύμπανος*, a drum; from *τυφλός*, blind; from *τύφος*, smoke, vapour, stupor, or conceit; and from *τύρός*, cheese. There is, for instance, *tylosis*, the name given to three medical states—to an inflammatory disease of the eyelids, to an affection of the mucous membrane of the lips and mouth, and (most commonly) to a callous condition of the skin of the palms and soles. The earliest illustrative quotation goes no further back than 1890, but *tylotic* is illustrated from the year 1883. *Tympanum*, a drum, has given rise to a large group of very interesting medical words, including the obsolete *tympan* ("a dysease in the bely, enfleure"), and the more modern *tympanectomy* and *tympanic*, and *tympanites* and *tympanitic*, and the big group of the *tympano-* compounds. The *Dictionary* illustrates interestingly the curious figurative meanings which have been attached to some of these medical terms. There is *tympanize*, for instance, whose original meaning was to affect with a tympany or to distend the abdomen with gas, but which came to signify to be puffed up, to be proud; and so, for example, came C. Harvey's line, "My windy thoughts with pride are tympaniz'd," and Nashe's statement, "The therd sonne of Pride is Atheisme, which is when a man is so tympaniz'd with prosperity . . . that he forgets he had a Maker." *Tympany*, too, has had a wide use in medicine, and, figuratively, outside of it. It has not been restricted to distension of the abdomen by gas or air in the intestine, but has sometimes been employed for any morbid swelling or tumour. Thus, although John Wesley in his *Primitive Physic* (a very popular book in its day) referred to "the Tympany or Windy Dropsy," Cotgrave (in 1611) wrote of "Mole, a timpanie, or Moone-

¹ *A New English Dictionary on Historical Principles*. Edited by Sir James A. H. Murray, Henry Bradley, W. A. Craigie, and C. T. Onions. Vol. X, *Turnadun-Tzirid*. By Sir James A. H. Murray. calfe, a shapelesse lump of flesh, or hard swelling in the wombe." But it was further extended to mean a pregnancy, and a quotation of 1590 says "The maid fell sicke, and her disease was thought to be a tympany with two heeles." Davenant (1649) has, "Midwives believe that it foretells A hopeful tympany to come." Donne (1610) is, of course, using it figuratively when he speaks of "this Tympany of false conception, by which" spiritual power is blown up, and swelled with temporall." How *typhlitis* comes from the Greek word meaning blind, and *tyroma*, *tyrosin*, and *tyrotoxin* from the Greek name for cheese, is plainly told, but the reader is left rather in doubt as to the connexion existing between *typhus* meaning pride, haughtiness, or conceit, and the "fever characterized by great prostration and a petechial eruption, and occurring chiefly in crowded tenements." The connecting link is to be found in the fact that whilst the Greek word *typhos* meant smoke or vapour and therefore vanity or conceit (mental smoke!) it also signified stupor, and that symptom is common in typhus fever. The distinction between *typhoid* and *typhoid fever* is well and clearly drawn, and it is to be noted that the earliest illustrative quotation of typhoid fever given is dated 1845 (Budd, *Diseases of the Liver*). There are not a few other interesting medical or semi-medical terms in this part of the great *Dictionary*, which has now reached the end of T, with some blanks in S to be filled in.

TELESCOPIC SIGHTS FOR RIFLES.

RECENTLY when discussing trench warfare with a sergeant on furlough from France, he was asked whether the German snipers were better shots than the English. He stated that the Germans were more successful because their snipers were provided with telescopic sights which were illuminated at night. This device, he stated, placed them at a great advantage as compared with our own men, who, he stated, had no such aids to efficient marksmanship. We are well aware that telescopic and mirror sights are delicate and easily damaged, and are in consequence not well suited for general military use. There seems, however, no valid reason why picked shots detailed for special duty should not be provided with the most effective sights which exist, even if the rifle so fitted require special care. Several optical sights have been devised, and some of them have done excellent service in match shooting. They may be divided into three classes—the use of lenses without any tube, as in the early aerial telescopes; the employment of lenses to give a reference line, with or without optical aid, the so-called collimating sights; and finally, telescopes, prismatic or otherwise, complete in themselves with arrangements for elevation and deflection, and with means for ready attachment to the rifle. The best known telescopic sight is that of Dr. Common, which he perfected in 1901; as regards principle it has not been improved on. The Zeiss prism telescope sight is really a small periscope; it has the disadvantage that considerable light is lost in the prisms, far more than in a simple telescope. In this sight, and in the similar Goerz prism sight, means are provided for illuminating the cross wires at night. An illustrated article on telescopic sights is to be found in *Nature* for February 3rd, 1916.

EXTINCTION OF BOMB FIRES.

THE committee appointed by the Home Secretary to make experiments to test the value of dry powder fire extinguishers, as compared with water and other "first-aid" appliances for extinguishing or effectively controlling fires such as are likely to be caused by bombs, has reported generally against the use of such powders, which it considers to be inferior to water.¹ Experiments were conducted by dropping an incendiary bomb through the first floor of a condemned house and allowing it to burn

for forty-five seconds. The original intention of the committee was to allow the fire to burn for three minutes before attacking it, but it was found that it had in the interval become so fierce that the operator was unable to approach near enough to apply the powder extinguishers. In one such experiment the fire was extinguished in six minutes by the application of 18 gallons of water from a small hose jet. The general conclusion of the committee is that none of the agents employed, including water, could be said to have any material effect on the combustion of the bomb itself, but that there was a great general difference between those experiments in which water was used and those in which dry powder was used. The spread of the fire caused by the bomb was greatly limited, and in some cases totally prevented, by the application of water, whereas after the application of dry powder the fire continued to burn, although at each application some temporary check to the fire was noted. Analyses made for the committee in the National Physical Laboratory showed that dry powder fire extinguishers generally contained as their main constituent sodium bicarbonate, the amount of which varied in the different samples examined from about 42 per cent. to nearly 56 per cent. Some of the powders analysed contained also varying proportions of calcium carbonate. Sodium bicarbonate when heated gives off a certain quantity of carbon dioxide gas, but the committee thinks it doubtful whether the quantity generated has a materially effective influence on the action of the powder as an extinguisher, except possibly in small fires of a special nature and limited extent. Water, though failing to extinguish the bomb itself in its earlier stages of combustion, was found far more effective than dry powder, the wetting of the surrounding material preventing the spread of the fire. Water proved itself also much the more effective extinguishing agent for the fires caused by bombs. The analyses of the dry powders made for the committee showed that if the whole of the carbonic acid available on heating were given off suddenly when the powder was thrown upon the fire, approximately 1 cub. ft. of gas would be formed for each pound of powder used. The smothering effect of this quantity of gas is contrasted with that of the enormously larger volume of steam generated by the vaporization of 1 lb. of water, which gives over 25 cub. ft. (or over 1,600 times its volume) of steam at atmospheric pressure. The committee states "that most of the dry-powder fire extinguishers sold in this country are retailed at prices which can only be described as extortionate considering the cost of their constituents. The substance said to be the vital constituent—bicarbonate of soda—may be bought at present for 4s. 6d. per cwt., or almost exactly ½d. per lb. Thus the cost of the bicarbonate of soda contained in a tin of powder of the usual size could not exceed 1½d., the other constituents being still cheaper." The committee also made some experiments with sand, which it found to be less effective, weight for weight, than the dry powder, though three buckets full of sand (about 144 lb.) extinguished a fire which three tubes of a dry powder, weighing nearly 13 lb., failed to do. The committee considers that similar smothering effects could probably be obtained from almost any dry inert substance in sufficient bulk. In conclusion, the committee expresses the confident belief that by far the best extinguishing agent is a plentiful supply of water applied in the manner most convenient, and that the use of powder fire extinguishers is to be deprecated not only because they give a misleading sense of security, but because they are practically useless for extinguishing or effectively controlling fires likely to be caused by bombs. As to the best way of applying water, the committee ascertained that the same amount of water was more effective when directed in a jet from an extinguisher than when applied by buckets. This was probably due to the greater force of the jet and to the easier means of directing it. The committee adds a word of caution as to using only

¹H.M. Stationery Office. [Cd. 8250.] Price 1d.

extincteurs of reliable make, since fatal accidents have occurred from the employment of extincteurs of faulty construction or unsuitable type.

BENEVOLENT FUND FOR THE R.A.M.C. TERRITORIAL, SPECIAL RESERVE, AND NEW ARMIES.

A MEETING of medical officers of the Territorial, Special Reserve, and new armies to consider further the advisability of establishing, for the benefit of the widows and orphans of officers, non-commissioned officers, and men, some kind of benevolent organization similar to that which exists in the regular Royal Army Medical Corps, will be held at the Royal Army Medical College on Thursday next, June 1st, when Director-General Sir Alfred Keogh will take the chair at 2.45 p.m. Meantime, we understand that Lieutenant-Colonel G. St. C. Thom, R.A.M.C., War Office, S.W., will answer inquiries as to the purpose of the meeting.

PATHOMETRY.

At the meeting of the Royal Society on November 11th, 1915, as was noticed in our columns at the time, Sir Ronald Ross read an introductory paper on pathometry, indicating the method he proposed to follow in studying the nature of the functions according to which the number of individuals infected with some disease should vary from time to time, on the supposition that the laws governing the rate of transference were already known *a priori*. The Royal Society, which published this first part of his paper in its *Proceedings* of February 2nd, has now made a special Government grant to assist him in carrying out the detailed calculations necessary for the second part of his paper. Miss Hilda P. Hudson, Sc.D., lecturer on pure and applied mathematics in the London University Department of the West Ham Technical Institute, has been appointed to assist in the work, which will be partly carried on in the Marcus Beck Laboratory of the Royal Society of Medicine.

AMERICAN MEDICAL MISSION.

THE United States authorities have appointed a medical mission to study war conditions in Europe. Its members—Colonel Bradley, Major Lyster, and Major Ford, of the United States army, and Surgeon Pleadwell, of the United States navy—have already arrived in this country. The members of the mission were entertained to dinner at the Athenaeum Club on May 24th by Director-General Sir Alfred Keogh and Sir William Osler, when they had an opportunity of meeting a number of officers of the Royal Army Medical Corps, the Canadian Army Medical Corps, and the Medical Service of the Royal Navy. Among the guests was the American Ambassador, who paid a striking tribute to the work done by officers of the Medical Services of the United States Army and Navy in the suppression of yellow fever and malaria, and in bringing ankylostomiasis under control in Puerto Rico and the Southern States. Sir Alfred Keogh endorsed this tribute, and had some weighty words to say on the importance of the study of administrative work and the too common neglect of it by men of science. The plans arranged for the mission include an inspection of the system of dealing with the sick and wounded in this country, to be followed by a study of the hospitals and other medical arrangements in France.

SIR JAMES ALFRED EWING, K.C.B., F.R.S., has been elected Principal of the University of Edinburgh, in succession to the late Sir William Turner. Sir Alfred Ewing, who is a graduate of the University (M.A. and Hon. LL.D.) has been for the last thirteen years Director of Naval Education; before that he had been in succession Professor of Mechanical Engineering in the Imperial University, Tokyo, of Engineering in University College, Dundee, and of Applied Mechanics in the University of Cambridge. His scientific work has been chiefly in the investigation of magnetism and the physics of metals.

Medical Notes in Parliament.

Military Service Bill.

THE Military Service Bill was read a second time in the House of Lords on May 18th. In moving the second reading Lord Sandhurst said that the Government had only two amendments to propose. One of these had reference to the recruitment of members of the medical profession. The amendment took the form of the following new clause, which was introduced into the bill in Committee on May 22nd:

Provisions as to Exemption of Medical Practitioners.—Regulations made under the second schedule to the principal Act shall provide for the establishment of professional committees to deal with claims for exemption made by duly qualified medical practitioners; and any application made by such a medical practitioner on any ground, other than that of conscientious objection, for a certificate of exemption shall be referred by the tribunal to whom it is made to such a committee in accordance with those regulations; and the recommendation of the committee on the application shall be binding on any tribunal constituted under the principal Act.

The amendment was accepted, and the bill containing this and other amendments was read a third time and passed on May 23rd. On the motion for the third reading Earl Kitchener made a statement, in the course of which he said that when the bill had received the Royal assent the process of recruiting would be carried out with the minimum possible inconvenience to the men themselves. The idea, he said, had apparently been prevalent in certain quarters that, for some wholly inexplicable motive, the military authorities were prone to crowd and even to congest the ranks with men physically unfit to bear arms. No suggestion could be wider from the truth. The power given under the bill to call up men for medical re-examination would be used not to absorb the physically unfit, but to secure the physically efficient. Some men were undoubtedly sheltering behind certificates acquired in an unsatisfactory way, or under a temporary condition of ill health. The terms of the bill would make it possible to use the men who were discarded on account of physical disability for active service but who were suitable for home service, clerical work, and the like. In a word, the bill made directly and unmistakably for equality of sacrifice in the national cause. The Army Council would use every effort to render it as easy as possible for the men to be called up. The groups would be kept open for voluntary attestation until the appointed date. There was no doubt that the armies in the field would welcome the measure with intense satisfaction. Generals and staffs would be able to count with greater certainty on the necessary drafts for reinforcements, and the rank and file would be encouraged by the thought that all their countrymen at home were prepared to support them to the utmost of their power.

The Lords' amendments were considered by the House of Commons on Wednesday, May 24th. In moving the clause as to the exemption of medical practitioners, Mr. Long said that it was the result of very patient examination by the War Office and representatives of the civil members of the medical profession in this country. The War Office had reason to be greatly anxious as to the provision of medical men for the army without undue depletion of the supply of medical men for civil work at home. The clause was supported by Mr. Rawlinson, but opposed by Mr. King, partly on the ground that doctors were not entitled to a special tribunal of their own profession, partly because the medical men already employed by the army were being wasted by being put to unsuitable work, and in other ways, partly because he did not consider that the Central Medical War Committee was sufficiently representative of the profession, and partly because it was another example of the wild militarism of the Government. Mr. King was called to order by the Speaker, on the ground that his speech had ceased to have any relevance to the clause. The clause was also opposed by Mr. Holt, on the ground that it was an attempt to enable the army to lay hands on doctors more freely than the local tribunals had permitted, and also because medical students had been taken away from their studies in the early days of the war, so that if it went on for another year or so the position would be very serious. He proposed to move an amendment, but was ruled out of order by the Speaker. Mr. Boyton also

opposed the clause, on the ground that the House had not sufficiently clear and definite knowledge of the real opinions of the profession. Sir F. Lowe objected to the tribunals being bound to accept the recommendations of the medical committees, and proposed to leave out the sentence at the end of the clause making this provision. Mr. Whitehouse supported Sir F. Lowe on the ground that it would limit the rights of medical men as compared with the rights of other men to go before local tribunals. Mr. Long agreed that the clause did not give a right of appeal, but it was clear that if a special tribunal was appointed *ad hoc*, there could be no appeal from it to another body which had general powers and was appointed to deal with general cases. The main reason for the clause was that the supply of medical men for military purposes throughout the country had been unequal. In some districts as many medical men had been taken as could possibly be spared; indeed, the margin had perhaps been too nearly approached. In other districts medical men could be spared. There was a strong desire, which did great honour to all concerned, that there should be a definite plan worked out by those who could survey the whole ground, and look not only at the particular case and the particular district, and would endeavour to maintain the supply for the R.A.M.C., and at the same time run no risk of depriving the civil population of the medical attendance they needed. Mr. Ronald McNeill inquired as to the nature of the recommendations to be made, and also appealed for further information. Mr. Charles Roberts, who replied to this appeal on behalf of the Government, said that the medical profession was in an exceptional position; it had special obligations to the civil population, especially that part which was insured. In order that all the circumstances of the medical profession in the various areas might be looked into a special committee of professional men, with local committees in different parts of the country, was a better authority to deal with the problem than a local tribunal, which could not really know the civil medical needs as well as the Central Medical War Committee, which for a year had been carefully watching the enlistment and enrolment of doctors, both from the point of view of the army and of the civil population. That Committee did not represent only the British Medical Association, but had been carefully chosen to represent every section of the medical profession. It could look into the case of each area, and was bound to prevent a breakdown of the medical service, at all events as far as the insured population was concerned. Mr. Pringle opposed the clause on the ground that there was nothing in the case of the medical profession more than other professions which entitled a professional committee to have the absolute decision as to which man in a particular locality should go to the front and which man should be left. He also urged that doctors had been used by the army with reckless extravagance. Mr. J. M. Robertson said that the cases were quite different, for, as a matter of fact, the army did not want lawyers as lawyers, nor shopkeepers as shopkeepers, but it did want doctors as doctors. Those who opposed the clause could not have it both ways: they could not argue that medical men were not to be specially considered or to have a special tribunal any more than any other profession, and then assert that we were in special straits as to the economizing of medical force. The medical body itself, acting locally, and a central body, with knowledge of the whole medical strength of the country, was best able to secure a total economy of the medical forces. He considered that the case for a special medical tribunal to say what persons shall go to the army and who are wanted for professional and not for combatant purposes was a very strong case indeed. After some other members had spoken against the clause the House divided, and the clause was carried by 163 to 42.

We learn that the War Office has decided to recognize, under the Regulations to be made in fulfilment of the above new clause, the three existing professional committees—namely, for *England and Wales*, the Central Medical War Committee (whose offices are at 429, Strand); and the Committee of Reference (appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England); and, for *Scotland*, the Scottish Medical Service Emergency Committee, whose offices are

at the Royal College of Physicians of Edinburgh. These committees have already, for some time past, been approved and recognized by the Government in the matter of arranging for the selection of medical men for service as doctors in the naval and military forces of the Crown, and in connexion with the work of the Central Tribunal. We are informed that an Order in Council under the new Clause and Regulations will be issued at once.

In practice the new clause will apply only to medical men who have not enrolled or do not now enrol. Army Council Instruction 485 (SUPPLEMENT, March 11th, 1916, p. 43) directed that after March 31st, 1916, the procedure should be as follows:

(a) If a qualified medical practitioner who is attested under the Group System, or is in one of the classes under the Military Service Act, 1916, and who is enrolled under the scheme of the Central Medical War Committee or the Scottish War Emergency Committee, or has been provisionally accepted by the War Office, receives a notice paper calling him up, he should return it to the recruiting officer, together with his certificate of enrolment or War Office letter. The notice will then be cancelled, and the practitioner will remain in reserve until selected for a commission in the Royal Army Medical Corps.

War Taxation and Finance.

The past week has not added much to our knowledge as to the final form of the Government's fiscal proposals for the current financial year. On the occasion of the second reading of the Finance (No. 2) Bill, the Chancellor referred to the hardship imposed on those persons who, receiving income taxed at the source at 5s. in the £, have, under present conditions, to wait until the end of the financial year before they can obtain a part or the whole of the tax so deducted, even though the title to repayment may be clear and indisputable. As a measure of redress, he promised that steps should be taken to provide for repayments in such cases being made half-yearly. The bill contains a clause, which has not attracted much comment in the daily press, but which throws an interesting light on the hardships arising from the operation of sharply defined lines of demarcation in a system of graduation. In the absence of special legislation, it is obvious that persons whose incomes just exceed any of the critical amounts—as, for instance, £600 or £1,500—are really worse off after payment of their increased tax than others whose incomes are just below the corresponding limits. The bill therefore introduces a novel principle, which is that a person may calculate his liability as if it did not exceed a particular limit, and pay over to the revenue officials the amount of tax so computed *plus* the sum by which his income does exceed the limit. The clause is certainly an ingenious means of avoiding hardship, but it introduces a complication which will make the calculation of an income tax liability more than ever of the nature of an arithmetical puzzle. It is to be noted that the Chancellor foreshadowed some readjustment of the scales of duty to bring the rates on small earned and small unearned incomes into closer relation with each other. We referred to this point in discussing the text of the bill, and it would now seem that some amendment of the rates of tax had then already been decided upon, if not actually settled.

War.

Invalid Prisoners in Switzerland.—On May 18th Mr. Theodore Taylor asked what steps were being taken to bring into operation the agreement under which British prisoners were being transferred from Germany to Switzerland, and German prisoners from Great Britain to Switzerland. Mr. Tennant replied as follows: "In order that there may be no unavoidable delay, an agreement has just been made with the German Government whereby the selection of those who are unquestionably included in the category of disabilities as justifying transport to Switzerland may be made by the medical authorities of the country where the prisoners are interned. The necessity for the majority of medical men on these selection boards being of Swiss nationality will be waived in this fresh selection. The necessary instructions have been issued." The Foreign Office has since made the following announcement:

In connexion with the transfer to Switzerland of British and German wounded and invalid combatant prisoners of war, whose disabilities do not bring them within the scope of the

agreement for repatriation, the decision whether a prisoner is eligible for transfer rests with medical boards on which Swiss medical opinion will be largely represented. The boards will visit all the camps where British or German combatant prisoners of war are interned, and all such prisoners will have the right to present themselves before the Board.

It will not be possible to bring individual cases to the notice of the Boards in any circumstances.

Medical Officers of Voluntary Military Hospitals.—Captain Douglas Hall asked on May 17th whether, in view of the fact that it was now proposed to give commissions and grant military rank to officers of volunteer corps, the War Office was prepared to grant similar privileges to medical officers in charge of voluntary military hospitals. Mr. Tennant replied that commissions had already been given to all medical men doing work which rendered military rank necessary. It was not proposed to recommend any further extension of the granting of temporary commissions in the R.A.M.C., except under this principle.

Temporary Officers R.A.M.C.—Mr. Joynson-Hicks asked, on May 18th, whether instructions had been issued that the contracts with temporary officers in the R.A.M.C. were not renewed unless the officers were passed fit for general service at home and abroad; and whether officers who were quite fit for home service could be utilized to release others on service abroad. Mr. Tennant's reply was to refer to the answer he gave on February 22nd, which was to the effect that temporarily commissioned officers of the Royal Army Medical Corps under 45 years of age and unfit for foreign service were not permitted to retain their commissions after the period of service for which they engaged had expired. No further commissions were being given to men under 45 years of age unless they were physically fit for active service. It was hoped by these methods to set free men who were physically capable of undertaking general military duties, and who had hitherto been employed in war hospitals in this country, or had been engaged in private practice.

Medical Practitioners' Chauffeurs.—On May 18th Mr. Boyton asked a question as to the difficulty experienced by consulting physicians and operating or consulting surgeons who devoted the whole or part of their time to work at the various military hospitals in getting chauffeurs of non-military age, and inquired whether the War Office would find soldiers to drive the cars of such physicians and surgeons as might apply and be approved. Mr. Tennant said that it would not be possible to release soldiers for this work. He had been told that women drivers had been employed in certain cases, and suggested that this was the solution of the difficulty. At the same time he desired to express his warm appreciation of the valuable assistance which had been given by consulting physicians and operating or consulting surgeons at the various military hospitals.

Position of Officers Resigned.—In reply to Sir C. Kinloch-Cooke, on May 17th, Mr. Tennant said that officers who had been found for various reasons inefficient in the discharge of their duties and had been allowed to resign their commissions became liable, if within the age limit, to be called to the colours under the Military Service Act.

Ration Allowance.—In reply to questions, on May 23rd, the Financial Secretary to the Treasury said that in those cases in which officers, to suit their own convenience, elected to take a money allowance instead of the ration in kind, the cash allowance was reduced in 1915 from 1s. 9d. a day to 1s. 5d. Following on a reduction in the meat ration by a quarter of a pound, the allowance had been further reduced to 1s. 3d.

R.A.M.C. Officers in German Typhus Camps.—On May 17th Mr. Malcolm asked whether the R.A.M.C. officers whose gallant behaviour at Wittenberg had been rewarded by His Majesty were volunteers for that particular work, or were detailed by the Germans to do it; and whether other British doctors in other typhus camps in Germany would be recommended for similar recognition. Mr. Tennant said that the three officers mentioned were detailed by the Germans for duty in the typhus camp at Wittenberg. It might be assumed that if other officers had done equally good work they would receive equal recognition.

Medical Examination of Recruits.—On May 15th Mr. Tennant said that he was inquiring into the facilities afforded to married men for submitting themselves to medical examination in order to ascertain whether their services would be required by the army. The War Office now announces that unattested men who desire can, by appointment, be medically examined by the medical board at the head quarters of the recruiting area in which they reside. It will be necessary for the man to apply by postcard to the recruiting officer nearest his place of

residence, so that arrangements may be made for an appointment, and he should wait until he is notified that such arrangements have been made.

Soldiers Physically Unfit.—On May 17th Mr. Cecil Harma-worth asked what was being done to release from service with the colours men physically unfit for any sort of arduous military duty, and whose return to civil employment was desirable in the interests of the army itself and of the trade of the country. Mr. Tennant said that men who were physically unfit for arduous military duty, but who could be usefully employed in the army to relieve men under training to go overseas, were retained in the service for this purpose. At present the number of these lower-grade men was insufficient to relieve from employments and fatigues all the fit men under training. Men who could not usefully be employed in the army were discharged unless they were likely to recover soon. In reply to Mr. Ashley, he added that many women clerks were being employed as substitutes for men in military indoor departments.

Artificial Limbs.—In reply to Mr. Hazleton, who asked whether disabled soldiers provided with artificial limbs would be required to renew such limbs, when worn out, at their own expense, Mr. Forster stated in a written answer, on May 18th, that repairs and renewals of artificial limbs were made at the public expense under the authority of paragraph 418 of the Regulations for the Army Medical Service.

Meat Prices.—In a written answer, on May 10th, Mr. Runc-man said that the price of South American beef had risen from 4d. for fores and 6d. for hinds on August 1st, 1914, to 8d. and 10d. respectively on May 1st, 1916. South American mutton had risen from 3d. to 9d., and South American lamb from 5d. to 9d.

THE WAR.

NOTES FROM SOUTH-EASTERN FRANCE.

(From an Occasional Correspondent.)

A CASE OF ARTIFICIAL ABSCESS.

A DOCTOR in charge of a French ambulance relates a case of simulation that has come under his notice which presents several points of interest. A soldier, aged 26, was hospitalized on account of a patch of "eczema" on the site of a former wound represented by a scar on the outer side of the knee. The skin over the affected area was uniformly red and dry, with flakes of desquamated epithelium corresponding to healing pustules, but its appearance at once excited suspicion on account of the sharply-defined edges, which were not raised, and the curiously symmetrical square shape. As, however, this might have been caused by an irritating dressing of some kind no comment was made. A few days later, when the man was about to be dispatched to his regimental dépôt, he suddenly developed another patch of dermatitis over the bursa patellae. The skin was florid, hot, and thickened, and there were a few small blisters filled with pus, without any thickened bases. Fluctuation could be felt, and, on squeezing, a grumous, sanguinolent pus welled out of two minute apertures such as would be made by a hypodermic needle. He was at once accused of having provoked the abscess, and ultimately admitted having injected paraffin. Our correspondent points out that the originators of these artificial abscesses often escape detection, because such cases are rare; it is not until, encouraged by their success, others seek to emulate their feats that suspicion is excited, whereupon close observation reveals the nature of the lesion. The substances employed for this purpose are, in the order of frequency: turpentine, paraffin, and petrol essence. The features to be remarked in this connexion are that these artificial abscesses are curiously painless, there is no glandular enlargement, and little constitutional reaction. The pus is grumous, non-homogeneous, containing much necrosed tissue, and is blood-stained. On evacuation of the pus, healing takes place with remarkable rapidity in the absence of secondary infection. Then, too, the pus, if examined bacteriologically, is found to be sterile. Pus from a paraffin abscess presents the characteristic odour, but from an abscess induced by turpentine or petrol essence the odour is faint. As a matter of fact, however, in the absence of a compromising odour, there is no absolutely pathognomonic sign, merely a group of highly suggestive features, so that a definite conclusion can only be arrived at by police methods, including close observation, inquiry, and exploration of the soldier's belongings (hypodermic syringe, phials smelling of the particular irritating agent, etc.). In view of the very grave consequences

Involved by such a charge, it is greatly to be desired that more trustworthy means of chemical or pathological identification could be devised.

A CASE OF EMOTIONAL MUTISM.

A robust young soldier was buried by the explosion of a shell at Verdun, and on being disinterred was found to have lost the faculty of speech. He was still mute when received at the inland ambulance a week later, though he understood what was said to him without difficulty, and could reply by signs. When directed to pronounce easy words, as "mamma" and "papa," he did not even move the lips, but with a little perseverance he was induced to whisper them. On laryngoscopic examination the vocal cords were seen to be completely paralysed in extreme abduction, and it was possible to see several tracheal rings. He was apparently quite unable to approximate them in the slightest degree. Judging from the absence of any reaction on the part of the pharyngeal mucosa, in spite of prolonged examination, there was also some anaesthesia. He remained in this state for a fortnight from the date of the traumatism, although on one occasion, not having bolted the closet door, he was startled by the nurse rushing in, which elicited an audible "Oh! pardon, madame." Even so the mutism persisted on his returning to the ward. He was sent to work in the vineyard, where, under the influence of plenty of wine and hard work, speech suddenly returned. This, indeed, is the universal experience—namely, that hard manual work is the best remedy for such functional incapacities of traumatic origin.

THE WAR AND THE BIRTH-RATE.

In all the belligerent countries, and not improbably in many others, the war is likely to have a disastrous effect on the birth-rate. In spite of the periodical issue of "tickets of leave" to men at the front, and notwithstanding a great, but probably much exaggerated, increase in the number of illegitimate births, the drop is simply tremendous. Evidence of this has been forthcoming from prolific Germany, and a correspondent who discharges the responsible functions of public vaccinator "somewhere in France" shows that the falling off is phenomenal. His observations bear on country parishes far removed from the sterilizing influences of urban life; so that the drop may fairly be attributed to absence of conception. The outbreak of war would naturally not greatly affect the number of infants coming up for vaccination in 1914, the year of the declaration of war, so this year may be taken as the standard. He finds that in a number of hamlets the infants eligible for vaccination in the years 1914, 1915, and 1916 were as follows:

1914.	1915.	1916.	1914.	1915.	1916.
7	4	2	16	10	9
11	4	3	11	2	1
15	8	5	10	6	3
7	1	1	22	13	7
12	9	1			
Total	106	57	11

In the town in which he resides the number of births, which was 173 in 1913, fell to 140 in 1914 and 86 in 1915. Taking the annual number of births in France as 775,000, and assuming that the decrease of vaccinifers corresponds to a paucity of babies, the fall during the year 1915, calculated on the above figures, which may probably be taken as a fair average for the provinces (outside the big towns where the returns are still more unfavourable), would amount to a loss of close upon 340,000, while in 1916 the loss will be not less than 541,000. If to this we add the direct loss of life on the battlefield and the enhanced mortality among the civil population owing to under-nourishment of infants, lack of adequate medical attention, and overwork among women, the sum total must be appalling in its magnitude. Nor is it to be hoped that the deficit will be made up after the war is over, because the immensely enhanced cost of living and the crushing taxation will infallibly make for voluntary sterility. The only consolation for France is that the sterilizing influence will tell on all countries and on all classes alike, though no doubt in variable degrees.

AUSTRO-GERMAN EXPERIENCES.

TWO UNFAMILIAR FEVERS.

Obscure Five-day Fever.

In a German field hospital on the east front Professor H. Werner¹ observed thirty-four cases, at first diagnosed as influenza, which subsequently showed a distinctive five-day type of fever. In each bout of fever the temperature rose to 38° to 40° C. for twenty-four hours, but sometimes for forty-eight hours. During the three- to four days' interval the temperature was steady. After a succession of such bouts the temperature ceased to rise and convalescence set in. The fever was accompanied by headache and pain in the limbs. The spleen was painful and the bones, particularly the tibiae, were tender. The patients were very tired and nervous. The rigor accompanying the rise of temperature was followed by a sense of excessive heat and perspiration, suggestive of malaria. The enlargement of the spleen was hardly demonstrable between the attacks of fever, during which the patients were flushed. In the afebrile interval they were pale and sometimes slightly jaundiced. The pain in the limbs increased during the febrile period and did not completely cease even when the temperature was normal. The micro-organisms of typhoid fever, malaria, and relapsing fever were not found. Possibly this five-day fever was an aberrant form of relapsing fever; and it was presumably identical with the "febris Wolhynica" described by His early in 1916. The following table is an example of the temperature in a typical case:

	A.M.	P.M.
December 25th ...	36.4° C.	39.4° C.
December 26th ...	36.9° C.	37.1° C.
December 27th ...	36.6° C.	37.0° C.
December 28th ...	36.5° C.	36.9° C.
December 29th ...	36.7° C.	37.0° C.
December 30th ...	37.2° C.	39.5° C.
December 31st ...	37.3° C.	36.7° C.

Gaiter-pain Fever.

Under the heading "Gaiter Pain" several Austrian writers have described a condition the most characteristic feature of which was severe pain in the shins. More than 200 such cases were observed by Dr. A. Grätzer² alone, from December, 1914, onwards, when his battalion was stationed on the Nida. In conjunction with Dr. Zanko he found that this "gaiter pain" was only one symptom, among many others, of a condition to which they gave the term "influenza polonica." The onset of the disease was acute, the temperature being sometimes over 40° C. at the outset. Severe headache was accompanied by stabbing pain in the region of the left costal arch, by great exhaustion, and frequently at first by constipation. Apart from the high temperature and considerable enlargement of the spleen, there was little objective evidence of disease. The spleen was strikingly hard, its lower border was sharply defined, and it was very tender. Herpes labialis was observed in a few cases. After three to four days, when the temperature had fallen below 38° C. and the headache had almost ceased, pain developed on the inner surface of the tibiae, of equal intensity on both sides. It was variously described as dragging, compressing, and throbbing. Its intensity was moderate in the morning, greater in the afternoon, and often unbearable at night. During the next few days the temperature became subfebrile or normal, and the spleen smaller and less tender. Large doses of salicylates and complete rest were alike useless, and it was only with a combination of morphine and veronal that a few hours' sleep could be secured. The disease sometimes lasted four to six weeks, during which the intensity of the pain showed slight variations, and the temperature was normal, or almost normal. At the end of this period improvement or recovery occurred, but in most cases during the following months there were frequent relapses accompanied by only slight rises of temperature, and hardly ever by any swelling of the spleen. The duration of a relapse was seldom as long as three weeks, but the pain was, as a rule, just as severe as at the first attack. Dr. Grätzer found large doses of quinine, given over a long

¹ Muench. med. Woch., March 14th, 1916.

² Wien. klin. Woch., March 9th, 1916.

period, shortened the course of the disease, and in many cases aborted relapses. The majority of the patients had never worn any kind of gaiter, and only in the case of an officer did the distribution of the pain coincide with the area covered by his gaiters. The disease was equally prevalent in marshy and in healthy districts; and while most of the cases occurred during the cold seasons, some of the worst were observed during the fine weather in June and July, 1915. The disease had certainly nothing to do with the wearing of gaiters, and it showed no definite relation to seasonal or local factors. It was certainly infectious, but the mode of its transmission from one patient to another was not ascertained, though Dr. Grätzer was inclined to suggest that it was conveyed by lice, as it flared up more frequently in some companies than others, although the whole battalion was living under the same sanitary conditions. The rarity with which officers developed this disease pointed in the same direction. The disease died out when the soldiers were on the march and slept in the open.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN ARTHUR CYRIL ALBERT JEKYLL, R.A.M.C., was reported as killed in action, in the casualty list published on May 20th. He was educated at Sydney University, where he graduated M.B.; he joined the army as a temporary lieutenant on March 15th, 1915, and was promoted to captain on completion of a year's service. He was attached to the Royal Scots, who lost nine other officers in the same casualty list—four killed, four wounded, and one missing.

Wounded.

Captain H. A. Pallant, R.A.M.C., temporary.

Lieutenant W. J. E. Stuttaford, R.A.M.C., temporary.

DEATHS AMONG SONS OF MEDICAL MEN.

Crawford, A. B., Captain West Yorkshire Regiment, son of Dr. A. D. Crawford, of Stanton Hill, killed in action, was educated at Oundle School, and was in practice as a solicitor at Boston. When the war began he enlisted in the Lincoln Regiment, and got a commission in the 14th service battalion of the Notts and Derby Regiment (Sherwood Foresters) on February 15th, 1915. He was a well-known cricketer, having played for both Notts and Warwickshire, and once made 51 against the Australians at Trent Bridge.

Daunt, Giles V., Second Lieutenant South Lancashire Regiment, youngest son of Dr. F. E. H. Daunt, of Clapham Road, London, S.W., killed in action on April 9th. His commission was dated December 29th, 1914.

Madge, Charles Albert, Lieutenant-Colonel South African Imperial Force, fourth son of the late Henry Madge Madge, M.D., of Upper Wimpole Street, killed on May 10th, aged 41. He was educated at Westminster, and went to South Africa with his regiment, the Royal Warwickshire, in 1900, served through the South African war, took part in the advance on Pretoria, was mentioned in dispatches, and gained the King's and Queen's medals with five clasps. In 1902 he was seconded for service under the Colonial Office, and in 1904 joined the Transvaal Consolidated Land and Exploration Company, and settled at Johannesburg. He served on the head quarters staff of General Botha in the campaign in German South-West Africa, and was mentioned in dispatches. On the conclusion of that campaign he came to Europe, and when killed was attached to the staff of a division. In 1910 he married Barbara, youngest daughter of Mr. H. Hylton-Foster, of Foxbury, Dorking, and Tolworth Hall, Surrey; and leaves a widow and two sons.

Mathews, R. H. F., 12th Yorkshire and Lancashire Regiment (Sheffield Battalion), in his 21st year, the second son of Dr. R. H. Mathews of Sheffield. He was educated at King Edward VII School, and had completed his first year as a medical student of Sheffield University, having obtained a scholarship. He joined immediately after the declaration of war.

Mitchell, Arthur Gorman, Second Lieutenant Royal Irish Rifles, son of Dr. A. B. Mitchell, of Belfast, killed in action, aged 19. He was educated at Campbell College, Belfast, and at Queen's College, Belfast, where he was studying medicine, and was a member of the O.T.C. He got his commission on May 8th, 1915.

Owen, Bruce Lloyd, Lieutenant-Commander R.N., fourth son of the late Dr. Lloyd Owen of Southsea, died at Newcastle-on-Tyne on May 16th. He attained that rank on June 30th, 1911, and was acting as commander at the time of his death.

Vardon, Evelyn F. Claude, Second Lieutenant Royal Dublin Fusiliers, only son of the late Dr. Evelyn Vardon, M.D., killed in action on May 12th, aged 36. He got his commission last July.

NOTES.

MR. T. YOUNG SIMPSON, F.R.C.S., of Plymouth, has been appointed Chirurgien Chef to the Hôpital Anglais 249 bis, Rhône, France. The hospital has 300 beds.

A committee of American surgeons and dentists has issued an appeal for funds to establish another special hospital in France for the treatment of wounds of the face and jaw. Accommodation for 500 patients is to be provided, and many well-known surgeons have offered their services. The French Minister of War has agreed to place a suitable building in Paris at the disposal of the promoters, and the American Red Cross will furnish supplies.

BRIGHTON HOSPITAL FOR OFFICERS.

Baths for the *eau courante* treatment of injuries of the arm and leg have been installed in connexion with the Red Cross Auxiliary Hospitals for Officers, Brighton. The apparatus was generously presented by H.R.H. the Princess Royal.

THE KUT GARRISON.

Mr. Edmund Candler, representative of the British Press with the Expeditionary Force in Mesopotamia, writing from the Mesopotamian front on May 9th, gives some account of the sufferings of the garrison at Kut, based on information given to him by four officers who had been in hospital there. The real privations of the garrison began in the middle of February. When the milk gave out the hospital diet was confined to corn-flour or rice water for the sick and ordinary rations for the wounded. On April 21st the 4-oz. grain ration gave out, and from April 22nd to 25th the garrison subsisted on the two days' reserve ration issued in January; and from April 25th to 29th on supplies dropped by aeroplane. The rations were supplemented to a certain extent by fish caught in the river. During the last days of the siege eight deaths were occurring daily among the British and twenty-one among the Indians. All the artillery horses and transport animals were killed for food, and mule flesh, it was said, was generally preferred to horse. Fortunately just before the force was besieged in Kut a large consignment of warm clothing had been received from the British Red Cross Society. This probably saved many lives, as the garrison had only the summer kit they stood up in. In addition to the four British officers, about six Indian officers, 100 British rank and file, and 963 Indian soldiers and followers were brought down from Kut in hospital ships, Turkish prisoners being given in exchange.

BRITISH RED CROSS MANUALS.

We are indebted to Mr. Hastings, secretary of the British Red Cross Society, for a set of the manuals¹ issued by the society at the price of 1s. each. No. 1, *First-aid Manual*, No. 2, *Nursing Manual*, and No. 3, *Training Manual*, are by Mr. James Cantlie, Honorary Surgeon-Colonel, R.A.M.C.(T.F.). They were all first published three or four years ago and are well known; since the war began they have been reprinted on many occasions. No. 4, *Hygiene and Sanitation Manual*, is by Lieutenant-Colonel S. Guise Moores, and was first published in January, 1914; it has been twice reprinted. It bears as motto the very true aphorism of Florence Nightingale: "You cannot improvise the sanitary care of an army in the field." All these manuals are well illustrated, coloured plates being inserted where necessary. No. 5, *Cookery Manual*, published last year, is by Mr. C. Herman Senn, and is intended for the members of voluntary aid detachments who undertake commissariat or kitchen duties, or who act as cooks. It consists for the most part of selected recipes, but contains notes on the preparation of camp kitchens, on the care of camp stores, on water supply, and on emergency utensils, including appliances for so-called fireless cooking.

GERMAN CASUALTIES.

An official announcement of the German casualties, as reported in German official lists, puts the total German losses from the beginning of the war to the end of last month at 2,822,079. This number includes corrections. The enemy losses during April (exclusive of corrections) numbered 91,162. The details are as follows:

	April.	Total.
Killed and died of wounds	17,455	664,552
Died of sickness	2,395	41,325
Prisoners	1,221	137,798
Missing	6,217	197,094
Severely wounded	14,557	385,515
Wounded	4,001	254,627
Slightly wounded	39,679	1,023,212
Wounded remaining with units	5,537	117,956
	91,162	2,822,079

The above figures include all German nationalities—Prussians, Bavarians, Saxons, and Württembergers. They do not include naval casualties or casualties of colonial troops.

Information has been published in France to the effect that the total casualties among officers in the German army number 71,857, including:

Killed	22,636
Wounded	43,334
Missing	3,762

¹ Published for the British Red Cross Society by Cassell and Co., Ltd., London, New York, Toronto, and Melbourne. 1915. (1s. net.)

England and Wales.

HEALTH CONDITIONS IN LONDON.

THE rise in the price of milk in London is generally believed to be in excess of what the economic conditions require. The price used to be 4d. a quart; it was then advanced to 5d., and is now 6d. in many districts. It is alleged that there is no scarcity of milk, that the recent rise in price is not justified by the conditions of the industry, and that it has merely resulted in greatly increasing the profits of farmers and milk dealers, probably mainly the latter. There can be no doubt that the rise has aggravated the problem of the artificial feeding of infants among the children of the poor, but it is satisfactory to find that the Board of Trade is making inquiries, which, we hope, may result in early action, for with the recent plunge into summer weather the problem is becoming acute. Another matter affecting the health of persons of all ages is also to be the subject of official inquiry. It has been stated recently that several metropolitan borough councils propose to abandon street watering during the summer in the interests of economy. The President of the Local Government Board informed the House of Commons on May 22nd that his medical advisers do not endorse the proposed policy, although he thought they would probably agree that there were cases where the amount of watering done in ordinary times might be reduced without risk. This may be so, although the experience of dry summers does not seem to make it probable. It would have to be shown that the total economy was very considerable in order to justify the stoppage of watering, more especially along routes much frequented by motor omnibuses and lorries. Apart from the discomfort inflicted on individuals at all sensitive to dust, and the extra domestic work caused by the inrush of dust through every open window, there is good reason to believe that dust is often the carrier of pathogenic organisms, especially of those which produce catarrhs of the upper respiratory passages. There is, indeed, a suspicion that recent outbreaks of acute anterior poliomyelitis may have been due to infected dust, and the fact that the county councils seem to be abandoning the tarring of the surface of many of the main thoroughfares out of London increases the importance of the whole matter. In reply to another question in the House of Commons Mr. Long said that the number of infant deaths in London and the large towns was this year below the average of the five preceding years and the infantile death-rate for London itself for the first quarter of 1916 was lower than that of the corresponding quarter during each of the last ten years; it has, however, to be remembered that the first quarter of this year was abnormally cold and wet. Mr. Long added that the Local Government Board was taking active steps, and with much success, to induce local authorities to adopt and carry out comprehensive schemes for maternity and child welfare, and that such schemes were already at work in nearly all the large towns and throughout a number of the counties. This general statement, however, does not meet the particular cases of the increase in the price of milk in London and the probable increase in the amount of dust in the air should the watering of streets and roads or their adequate tarring be suspended.

THE SYPHILIS DEPARTMENT OF THE LONDON HOSPITAL.

We published in December, 1913, a fairly full account of the scheme for the establishment at the London Hospital of a special department for the treatment of syphilis, and in February, 1914, we were able to announce that the Grocers' Company had generously promised to provide the necessary indoor accommodation at the cost of £7,000 to £10,000. It was then determined to add another floor to the existing isolation block, the cost of which, owing to structural difficulties, amounted to £10,000. The building was delayed on account of the war but was completed by the end of 1915. Owing to financial stringency it was at first proposed to postpone opening the department until the end of the war; but, in view of the great increase in the number of patients presenting themselves for treatment, the House Committee determined to open it on March 1st, 1916. It provides eight beds for men and eight for women in separate rooms, with

bath-rooms and accommodation for sister and nurses, as well as a well-equipped laboratory for clinical investigations. It is worked in connexion with the skin department of the hospital, and is intended specially for the treatment of syphilis in the acutely infective stage. The President of the Local Government Board has taken a great interest in the work, and recently paid a visit to the department, which fulfils in all respects the recommendations of the Royal Commission on Venereal Diseases.

MEMORIAL TO THE LATE DR. FREDERICK LAWRENCE OF HAMMERSMITH.

On Sunday afternoon, May 21st, the Bishop of London, at a service in St. Peter's Church, Hammersmith, dedicated a chime of bells and unveiled a marble tablet which had been subscribed for by friends and patients of the late Dr. Frederick Lawrence, who died in his 85th year on May 1st, 1915. A medallion portrait of him is carved upon the tablet, and beneath it is an inscription referring to his attendance at the church for over fifty years, to his services as churchwarden since 1906 until his death, and to his practising in the neighbourhood for over half a century. After the bells had been blessed a short peal rang out from them, and the tablet was unveiled. The bishop, in an eloquent address, spoke of the supporting influence of the Christian faith to the community at home as well as at the front, and the purging effect of the war. In the course of it he several times referred to "our dear old friend." Besides the clergy engaged, Sir William Bull, M.P., the Mayor and Corporation of Hammersmith, and many friends and patients of the late Dr. Lawrence were present at the service. There were among them soldiers, in hospital dress back from the front, some in khaki, and a guard of honour formed by the St. Peter's Company of the Church Lads' Brigade.

TREATMENT OF SCHOOL CHILDREN IN LIVERPOOL.

The city council has finally decided to take measures to secure efficient treatment of school children suffering from adenoids and tonsillar affections. There was some slight opposition to the recommendation of the Education Committee on the ground apparently that it was thought that such treatment did not come within the purview of a committee whose object was solely educational. There also was not absent a feeling that parents might have a conscientious objection to such treatment as being an infringement on their rights. The recommendation was, however, approved and a clinic will shortly be established, and one more step towards medical treatment as a natural corollary to medical inspection under municipal control has been taken. At present nothing has been done for the treatment of diseases of the skin in school children, and that, it is considered, should be the next step.

LIVERPOOL ROLL OF HONOUR WEEK.

During the week May 7th-13th the Lord Mayor of Liverpool made an appeal to all classes of the community with the object of establishing a fund for the widows, orphans, and dependants of Liverpool men who fall in the war. The medical profession, through the Liverpool Medical Institution, has contributed £600, free from any deduction connected with collection. This sum is regarded as most satisfactory when it is considered that many medical men are away on active service. Mr. William Jones, the resident librarian, was untiring in his efforts for the fund, and his services deserve to be placed on record. Down to May 22nd the city's Roll of Honour Fund amounted to £52,586 5s. 4d.

Scotland.

THE plans for the Royal (Dick) Veterinary College, Edinburgh, have been completed by the architect, Mr. D. M'Arthy. The front portion of the building will provide for the teaching and administration, and will contain laboratories, lecture theatres, and a hall to seat three hundred persons, as well as a museum, photographic rooms, students' reading and smoking rooms, and rooms for the professors. The clinical department, which will be in the rear part of the building, has been designed for the treatment of all kinds of animals, there being special

accommodation for horses, cows, and sheep, wards for dogs and cats with enclosed runs, and operating theatres for large and small animals respectively. X-ray and photographic rooms will be provided for both departments.

It was announced in the JOURNAL of April 1st, p. 503, that an assistant county medical officer and tuberculosis officer had applied to the tribunal for the Lorn district for exemption from military obligations on the ground that he believed war to be morally wrong and indefensible, and that he was unwilling even to serve in the R.A.M.C. The tribunal refused the application, and an appeal to the Argyllshire Appeal Tribunal has been dismissed.

HOSPITAL FOR MAIMED SOLDIERS AND SAILORS.

Good progress is being made with the establishment of the Princess Louise Scottish Hospital for Soldiers and Sailors. A house was placed at the disposal of the committee for the period of the war and twelve months afterwards by Mr. Thomas Aikman, with the option of purchasing the house and certain land about it on moderate terms. The committee did not consider it advisable to spend any part of the money subscribed by the public in acquiring land, but a citizen of Glasgow (who remains anonymous) has arranged to purchase the house and about 350 acres of land and to present it to the committee. The offer was gratefully accepted on May 16th. It was made through Mr. William Guy, one of the honorary secretaries, 146, Buchanan Street, Glasgow.

MATERNITY AND INFANT WELFARE SCHEME FOR DUNDEE.

The Public Health Committee of the Dundee Town Council at its meeting on May 18th adopted a scheme for maternity and child welfare centres. The convener, Mr. Simon Fraser, said that the record of infant mortality in Dundee during the last twenty years put the city in a most unenviable position. It was the worst in Scotland, and last year had been particularly disastrous. The scheme provides for the extension of the system of visiting mothers by the appointment of additional health visitors, who would also visit homes from which measles and whooping-cough were reported, and advise the mothers as to the measures necessary for the prevention of the spread of these diseases and of their complications. The M.O.H. is empowered to engage trained nurses temporarily for the work of visiting all infected homes whenever the necessity arises, and the Local Government Board for Scotland is to be asked to make the notification of measles and whooping-cough compulsory, as it is in England. The medical staff of the Royal Infirmary is to be asked to institute pre-natal clinics in connexion with the Maternity Hospital. It is intended to co-operate with the Infant Welfare Committee of the Social Union in attending to the health of expectant and nursing mothers and providing baby clinics and baby hospitals. A central institution for maternity and child welfare will be established where the inspector of midwives and the lady health visitors will reside. In addition there will be three baby clinics in different parts of the city. Dr. Templeman, M.O.H., said that it was desirable to place at the head of the work a medical woman who would be required to devote her whole time to it. She would get into touch with the cases reported by the health visitors, so that there would be continuity of treatment. The estimated cost of the scheme for the first year is about £1,000.

Canada.

THE INTERNATIONAL JOINT COMMISSION.

A MEETING of the International Joint Commission on Boundary Waters was held at Washington, D.C., on March 8th and 9th, to consider the final report on the engineering investigations which have been made during the past year. The Commission consists of three members from Canada and three from the United States, and is a permanent tribunal for the adjustment of boundary matters between the two countries under the terms of the treaty between Great Britain and the United States of January 11th, 1909, which states that "the waters therein defined as boundary waters and the waters flowing across the boundary shall

not be polluted on either side to the injury of health or property on the other." In 1913, as the result of complaints that the terms of this treaty were being violated, the Commission was asked to determine whether or not this was so, and, if it was, to what extent, at what points, and by what causes; and, secondly, to report on the remedies considered advisable. In January, 1914, a progress report was published, which stated that the boundary waters were grossly polluted to the detriment of the public health; in the Great Lakes, however, the pollution was found to be confined to the shore fronts. This part of the inquiry was conducted under the direction of Dr. Allan J. McLaughlin, of the United States Public Health Service, with whom were associated Dr. J. W. S. McCullough, Dr. J. A. Amyot, and F. Dallyn, of the Provincial Board of Health of Ontario. The second part of the inquiry is in the hands of Professor Earle B. Phelps, consulting sanitary engineer, who has just completed his report.

THE CANADIAN RED CROSS SOCIETY.

At the annual meeting of the Canadian Red Cross Society in the Convocation Hall of the University of Toronto, when the Duke and Duchess of Connaught and the Princess Patricia were present, as well as the Lieutenant-Governor of the Province and Lady Hendrie, the chair was taken by the President of the society, Surgeon-General G. Sterling Ryerson, who expressed to Her Royal Highness the Duchess of Connaught the desire of the members that she should become its president. This she graciously agreed to do. Favourable comment on the work of the society was made by His Royal Highness, who also expressed his satisfaction with the harmonious relations existing between that body and the St. John Ambulance Association and Brigade. The society is to be congratulated upon having as its president the Duchess of Connaught, who ever since the commencement of the war has shown the greatest interest in its work. General regret, however, is felt upon the retirement from the presidential chair of Surgeon-General Sterling Ryerson, to whom the society owes its inception. The Canadian branch of the British National Society for Aid to the Sick and Wounded in War was founded in 1896, and was incorporated under its present name in 1909. Its success has been due in large measure to the active support and unflinching energy of such men as Surgeon-General Ryerson and the late Lieutenant-Colonel Jeffrey Hale Burland. As a mark of appreciation of the services rendered to the society by Surgeon-General Ryerson during his two years' occupancy of the presidential chair, the following resolution was passed unanimously at a meeting of the Central Council on February 1st:

That on the retirement of Surgeon-General George Sterling Ryerson from the office of president of the Canadian Red Cross Society in order that the society may be honoured by H.R.H. the Duchess of Connaught graciously accepting that position, the Council desire to place on record an expression of appreciation of the long and active service of General Ryerson in connexion with Red Cross affairs and administration in this country. As the original promoter of the foundation of the society in Canada, as chairman of the Executive Committee, as the Special Commissioner to South Africa representing the Canadian Red Cross Society during the Boer war, and as the president of the society for the last two years, he has all through been a leader in Red Cross work, and has evinced great enthusiasm as well as ability in serving the society. The Council further expresses the hope that Surgeon-General Ryerson's close connexion with the society and the administration of Red Cross work will long continue, so that we may have the benefit of his great experience and familiarity with Red Cross matters generally.

It will be remembered that Mrs. Ryerson lost her life in the *Lusitania* disaster. Miss Laura Ryerson, who also was on board, has been made Lady of Grace of St. John of Jerusalem, in recognition of her "courage, fortitude, and unselfish devotion in the *Lusitania* disaster." Miss Ryerson was thrown into the water from one of the boats. She swam about for three hours, during which time she went down twice. Finally she succeeded in reaching a raft on which one member of the crew was standing. He pulled her out of the water. Subsequently they caught a lifeboat, which was drifting past, and with it saved the lives of many of the women who were clinging to preservers. All of the women, with the exception of Miss Ryerson, collapsed when they were taken from the life-

boat by the destroyer. Miss Ryerson undressed the women, wrapped them in blankets, and took care of them.

Correspondence.

IN MEMORY OF THE THREE BRAVE DOCTORS WHO DIED AT WITTENBERG.

SIR,—Many of us must feel deeply that some memorial should be put to the memory of the three brave doctors who died at Wittenberg camp of typhus fever while doing their utmost to alleviate the terrible suffering and misery of which we have all read with a thrill of horror from the reports of Major Priestley, R.A.M.C., and Captains Vidal and Lauder.

His Majesty has voiced all our wishes by the honours he has graciously bestowed on these gallant men who mercifully survived, and we now feel that the names of those who died—Major W. B. Fry and Captains A. A. Sutcliffe and S. Field—should be remembered in the years to come. I think all will agree that if possible the memorial should take the form of helping to alleviate suffering and do some permanent good, but that must necessarily depend on the amount received. I will gladly receive and acknowledge the smallest sums, as I feel all men and women will wish to join in honouring the memory of such men.—I am, etc.,

CONSTANCE PARKER OF WADDINGTON.

Aldworth, Haslemere, May 20th.

HOW MEDICAL WRITINGS MAY BE GIVEN A MARKED DEVELOPMENT.

SIR,—Dr. Mercier has gone to considerable trouble and taken up valuable space in abusing medical writers in general merely on account of a passage in which the word "marked" is used so frequently and at such short intervals as to render the passage as unnecessarily tautological as such repetition is ridiculous. Dr. Mercier, however, seems totally unaware of the fact that the verb "to mark" and its adjective, "marked," are perhaps as capable of as many shades of meaning as any words in the language. A few minutes' study of any good dictionary should convince him of this. Dr. Mercier has therefore no right to take upon himself the attempt to limit either adverb or adjective to their most primitive meaning—that is, to mark as with a line or dot, a fact which he plainly infers in the following sentence: "If he wishes to say that a rash is copious let him say that it is copious and not that it is marked, which it is not." The word "copious" is only adequate in the case of a rash when the rash is diffuse or distributed widely over the surface. It does not convey the same meaning as to intensity as the word marked does. We can say slightly marked, deeply marked, well marked. The word copious, on the other hand, has no such flexibility, being too closely bound to the superlative degree to be capable of modification by adjectives or adverbs to the extent which may be required, and hence is totally inadequate as a substitute.

If Dr. Mercier will go to the trouble to look up the word "development" in the *Imperial Dictionary*, vol. ii, he will find the following definition: "The exhibition of new features; a gradual growth or advancement through progressive changes." Surely Dr. Mercier must admit that there could be no better justification than this definition for the use which the majority of the best medical writers make of this word, and its verb and its adjective, whether in connexion with pneumonia or cancer or any other pathological change. Dr. Mercier should have remembered that the verb "develop" has both a transitive and an intransitive meaning, and that the transitive meaning is of far wider application than its mere connexion with a certain process in photography, and that it was used in a transitive sense long before photography was ever thought of or heard of.

I would like also to point out that the expression "he was given a pill," whatever its faults may be, is far less offensive to an educated intellect than the somewhat vulgar and meaningless combination "sloppy English." Had the costermonger's adjective been substituted for the word "sloppy" the expression would have conveyed neither more nor less meaning. Such an expression, to

adopt the phraseology which Dr. Mercier considers more elegant or intelligible than "markedly worse," is "a thundering sight worse" than anything we have been accustomed to see in the *BRITISH MEDICAL JOURNAL*.—I am, etc.,

Liverpool, May 21st.

WILLIAM BRAMWELL.

SIR,—I think Dr. Mercier errs in attributing to Tennyson the words, "Evil is wrought by want of thought as well as want of heart." They certainly occur in the *Lady's Dream*, by Hood, and I cannot remember them in any of Tennyson's writings. I am glad of the opportunity of saying that gratitude is due from us to Dr. Mercier for his plea on behalf of greater clearness in medical writings, and for clearness of thought in general. Slipshod speech and slang expressions are constantly being thrust upon the better educated by the less educated class, and it is to be feared that the tendency of many educational reformers will not be in favour of purity of speech and writing. All the more honour to Dr. Mercier!—I am, etc.,

May 22nd.

M.D.

THE MEDICAL OFFICERS MERCANTILE MARINE.

SIR,—1. In my opinion no shipping master in any British port should enter the name of any medical officer on a ship's articles without a certificate from the medical officer of the local port sanitary authority that he has verified the status of the medical officer and communicated the name to the Registrar of the General Medical Council in London for entry on a temporary list of medical men employed in the mercantile marine—to be kept by the General Medical Council.

2. When a mercantile company discharges a medical man from its employment it should send in his name to the medical officer of the port sanitary authority, so that this official may inform the Registrar, General Medical Council, of the occurrence.

3. When a medical man has served six months at sea he should be permitted to go through a course of instruction in naval hygiene at the Royal Naval classes for medical officers, R.N., at Greenwich, and, if successful, get a commission in the Royal Naval Reserve, as do the ordinary deck officers of the mercantile marine. The only way that I can see to give protection and defined status to the medical officers, mercantile marine, is by following some such lines as these. The cost to the State would not be greater in proportion than is the cost of training the ordinary Royal Naval Reserve deck officers, and in a similar way a war reserve would be developed for the Royal Navy.

4. The cry of the ship surgeon class for just conditions cannot be longer ignored.—I am, etc.,

GEORGE J. H. EVATT, M.D.,

London, S.W., May 19th.

Surgeon-General.

THE INDIAN MEDICAL DEGREES BILL.

SIR,—In the report of the annual meeting of the Bombay Medical Union that appeared in your issue of April 29th (p. 632), I was very pleased to notice that the members of that union held an open mind as regards the Government recognition of the Yunani (Muselman) and Ayurvedic (Hindu) systems of medicine. While in India about two years ago I was much impressed with the good work carried on by many Ayurvedic physicians, some of whom are qualified men with medical diplomas from the Indian universities. The Ayurvedic colleges in India are training men in anatomy, physiology, pharmacy, and medicine, and are doing research work by translating Sanskrit medical works and reinterpreting them in the light of modern medical science. When I drew the attention of Lord Pentland, the Governor of Madras, to the scientific work carried on by the Ayurvedic colleges in Madras, His Excellency showed his sympathy by his visit to the college. Any indigenous attempt to bring together the European and Indian medicine ought to be welcomed by all well wishers of India. For it is only by this way that the great mass of the Indian people will take kindly to Western medicine and a lasting union between England and India will be made. It is therefore I plead that the work of the Ayurvedic colleges should be encouraged and should find recognition in the Medical Degrees Bill now before the Indian Government.—I am, etc.,

Wells, May 7th.

G. MUTHU.

TREATMENT OF CHLORINE GAS POISONING.

SIR,—I have not noticed that it has occurred to any of the R.A.M.C. men at the front to try the effect of venesection in acute poisoning by chlorine gas. It appears to me, seeing that the fatal effects are due to obstruction in the pulmonary circulation and oedema of the lung tissue, that copious blood-letting is the only remedy which could be expected to produce any immediate effect. It is at any rate worth trying, if it can be applied soon enough.—I am, etc.,

Edinburgh, May 24th.

E. A. SCHÄFER.

THE SPELLING OF "NEURON" AND "AXONE."

SIR,—I have to apologize for an error of confusion in my review of Gaskell's *Involuntary Nervous System* in last week's issue of this JOURNAL. While the "o" in "axone" is clearly long (ἄξων) that in νεύρον is, of course, short. It is only, therefore, for the sake of uniformity if the final "e" is added to "neurone." On the whole, perhaps, as Professor Sherrington has suggested to me, it would be better if neurologists agree to spell "axone" with the "e" and "neuron" without it. The latter word should, of course, be pronounced as if ending in the preposition "on."—I am, etc.,

University College, W.C., May 22nd.

W. M. BAYLISS.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on May 11th, when Sir Watson Cheyne, President, was in the chair.

Diplomas.

Diplomas were given to ninety-nine candidates found qualified for the Membership of the College at the recent examinations.

The Cartwright Prize.

The subject for this prize for the period ending December 31st, 1920, is, "The treatment of injuries of the jaws, and the restoration by mechanical means of parts of the jaws lost as a result of injury, or removed on account of disease." The prize consists of a bronze medal and an honorarium of £85, and is open to persons engaged in the study or practice of dental surgery, and possessing qualifications capable of registration under the Medical Acts of the United Kingdom. (A diploma or licence in dental surgery, without a medical or surgical diploma or degree, will not be a sufficient qualification.)

In reference to a letter from a correspondent published last week criticizing the present arrangements for the election of the Council of the Royal College of Surgeons, we are informed that the President and Council are not empowered to arrange for any temporary modification of the rules, and that the alteration of a by-law is a lengthy and complicated procedure.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following have been admitted Fellows: Dines Chandra Chakravati, W. W. Hoare, G. R. Livingston, A. C. Sandstrom, N. F. Sinclair, H. M. L. Staley, Muhammed Abdul Wajid.

The Bathgate Memorial Prize in materia medica, consisting of bronze medal and microscope, has been awarded to Miss Marguerite R. Sterling.

The Ivison Macadam Memorial Prize in chemistry, consisting of bronze medal and set of books, has been gained by Miss Janet Grant.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SURGERY.—H. H. Bailey, *A. Glen, *H. M. Hobson, *E. G. D. Murray.
 MEDICINE.—*H. H. Bailey, *P. C. C. Fenwick, *R. F. Jarrett, *E. G. D. Murray, *H. F. Pain, *M. B. M. Tweed.
 FORENSIC MEDICINE.—R. F. Jarrett, L. A. B. Moore, E. G. D. Murray, A. W. North, L. F. Pain.
 MIDWIFERY.—M. Dwyer, H. T. Lamb, E. A. Leak, A. W. North, S. L. Szpigner, M. B. M. Tweed, H. St. H. Vertue.
 * Section I. † Section II.

The diploma of the Society was granted to Messrs. M. Dwyer, A. Glen, A. W. North, and L. F. Pain.

THE United States Government's "safety first" train left Washington, D.C., on May 1st, on an educational tour through all parts of the United States. It carries hundreds of exhibits illustrative of the methods employed by the Federal Government for saving human life and property. It is believed that the number of deaths and injuries from accidents can be reduced by one-half through "safety first" methods.

Medico-Legal.

SENTENCE FOR PRETENDING TO BE A QUALIFIED PRACTITIONER.

ACCORDING to a report in the *Scotsman* for May 17th, a young man named George Bowie Farquhar was charged before the sheriff of Linlithgow on May 16th with having pretended to Dr. W. T. Lindsay, of Blackridge, that he was a duly qualified medical practitioner, and thus inducing Dr. Lindsay to engage him as locum-tenent, and to pay him £6 5s. a week for a period of six weeks and three days. The accused pleaded guilty. It was stated on his behalf that he had a knowledge of chemistry, had taken some preliminary examinations in medicine, and despite the want of qualification had given satisfaction. The sheriff said that he would not be doing justice in the public interest if he failed to impose the highest sentence in his power, which was imprisonment for three months.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Deputy Surgeon-General D. J. P. McNabb and Fleet Surgeon J. F. Hall have been appointed respectively Deputy Director-General and Assistant Director-General of the Medical Department of the Admiralty.

EXCHANGES.

LIEUTENANT R.A.M.C.T., with considerable surgical experience, is anxious to be transferred to a casualty clearing station, preferably in the Southern Command. Address, No. 2050, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

M.O. to Divisional Train, Army Service Corps, probably at home for some time, desires immediate exchange with M.O. in 50th Division abroad—Apply No. 1950, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Obituary.

WE regret to announce the death, on May 12th, of Dr. JOHN HEPBURN LYELL of Perth. He had been in indifferent health for some months. He was a native of Newburgh, Perthshire, was educated at Perth Academy, studied medicine at St. Andrews and Glasgow Universities, and graduated M.B., C.M. in 1896 and M.D. in 1901. Dr. Lyell was closely identified with Perth and its institutions. He was for a period house-surgeon to the Royal Infirmary, and after he commenced practice was appointed one of the visiting physicians to that institution, acting also as medical electrician and radiologist. Dr. Lyell was assistant medical superintendent to Perth Prison. He took a keen interest in the affairs of the British Medical Association, and was secretary to the Perth Branch for some years; he was also joint secretary to the Local Medical and Panel Committees of Perth and Perthshire. A keen lover of science, he was identified with the Perthshire Medical Science Society, and contributed several papers on scientific subjects. Dr. Lyell is survived by a widow and three children, to whom the sympathy of a large circle of friends will be extended.

DR. JAMES BRUCE RONALDSON, who for many years practised in Haddington, died in retirement at his residence in Colinton, Midlothian, on May 17th, aged 65. He received his professional education at Queen's College, Belfast, Dublin, and Edinburgh, and took the diplomas of L.R.C.P. and L.R.C.S. Edin. and L.A.H. Dubl. in 1874. In 1884 he became F.R.C.S. Edin. and in 1890 D.P.H. He graduated M.D. St. Andrews in 1895. He was for a time M.O.H. for the Burgh of Dunbar, and for many years held the appointment of medical superintendent of Haddington District Asylum, besides conducting a large private practice. For upwards of thirty years he served in the 8th Battalion of the Royal Scots, attaining the rank of honorary surgeon-colonel, receiving the Volunteer Decoration for long service. Dr. Ronaldson contributed to the JOURNAL (vol. ii, 1907, p. 1826) a report of the death of a gamekeeper from a single pellet wound. The pellet had passed through the conjunctiva on the nasal side of the eyeball, splintered the orbital plate of the ethmoid, traversed the left cavernous sinus, divided the internal

carotid artery, run along the substance of the pons, and lodged between the lobes of the cerebellum. Dr. Ronaldson was held in high esteem alike among his friends and in professional circles. He leaves a widow and a son—a member of his father's profession, at present on war service.

DR. CHARLES CHAPMAN SKARDON died at his residence in Audley, North Staffs, on May 14th, aged 62. He was a native of Plymouth, and after studying at the medical schools of St. Bartholomew's and St. Mary's he took the diploma of L.S.A. in 1883. He settled in practice at Evershot, Dorset, and later in London. For the last six years he practised in Audley, Staffs, where he was highly esteemed by his patients.

DR. JAMES ANDERSON of Poulton-le-Fylde, Lancashire, died on April 9th, aged 64, of acute pneumonia. He was born in Johnston, Renfrewshire, and took the degree of M.B.Glasg. and the diploma of L.R.C.S.Edin. in 1877. After holding the appointment of resident surgeon to the Paisley Infirmary he went into practice in Poulton-le-Fylde, where he remained for thirty-eight years. In April, 1901, he was appointed a member of the Poulton Urban District Council, resigning his seat in 1902, when he was elected medical officer of health, an appointment which he held till his decease. He was also medical officer for the Poulton district of the Fylde Union.

DR. BARTHOLOMEW EDWIN MCKENZIE, of Toronto, who died on April 21st, was one of the first Canadian surgeons to devote himself to the study of orthopaedics. He was born at Oak Ridges, Ontario, in 1851, and was educated at the Cobourg Collegiate Institute. In 1877 he graduated at Victoria University and was awarded the silver medal for mathematics. He then entered the medical school of McGill University and received the degrees of M.D., C.M. in 1880. He subsequently did post-graduate work in London, Glasgow, Berlin, and Vienna. After engaging for a few years in general practice in Toronto, he specialized in orthopaedics. He was the founder of the Orthopaedic Hospital and was actively connected with its work almost up to the day of his death. In 1905 he was elected president of the American Orthopaedic Association. He was also associate professor of clinical surgery at the Medical College for Women, Toronto. Dr. McKenzie was a strong advocate for temperance and believed in advanced temperance legislation. He was the opponent of Dr. Pyne at the last provincial elections, but was defeated on the "banish-the-bar" issue.

COLONEL WILLIAM LITCHFIELD CHESTER, Army Medical Staff (retired), died at Coney Green, Upper Hatherley, Cheltenham, on May 5th, aged 65. He was born on February 17th, 1851, and educated at Trinity College, Dublin, where he graduated B.A. in 1872 and M.B. and M.Ch. in 1874. Entering the army as surgeon on March 31st, 1875, he became surgeon-major on March 31st, 1887, surgeon-lieutenant-colonel on March 31st, 1895, and full colonel on August 19th, 1903, retiring on February 17th, 1906. He served in South Africa in 1881 in the first Boer war, taking part in the campaign in the Transvaal, and in the Sudan in 1884-85, in the Nile campaign, receiving the medal with a clasp and also the Khedive's bronze star.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Henry L. Elsner, professor of medicine in the University of Syracuse, New York, aged 60; Dr. Giuseppe Magini, professor of histology and general physiology in the University of Rome, aged 64; Dr. R. H. Whitehead, professor of anatomy and dean of the medical department of the University of Virginia, Charlottesville, one of the leading anatomists in the United States, author of *The Anatomy of the Brain* and of many contributions to anatomical literature, aged 50; and Dr. Elphège Hamelin, sometime professor of therapeutics in the University of Montpellier, aged 75.

AN anonymous donor has offered the sum of £100,000 towards the establishment of a psychopathic hospital in New York.

Medical News.

THE Cavendish Lecture before the London Medico-Chirurgical Society will be delivered by Sir John Bland-Sutton, F.R.C.S., at the West London Hospital on Friday, June 23rd.

THE Royal Dental Hospital, Leicester Square, has received a donation of £400 from the trustees of Smith's (Kensington Estate) Charity and £100 from the executors of the late Mr. William Johnston.

DR. THOMAS LEWIS (London) requests us to state that he has retired from practice.

IN accordance with the will of Professor J. William White, of Philadelphia, an obituary notice of whom appeared in the BRITISH MEDICAL JOURNAL of May 20th, his brain has been placed in the Wistar Institute of Anatomy of the University of Pennsylvania, where it will be kept in the laboratory for scientific study.

THE London Committee of the French Red Cross (9, Knightsbridge, S.W.) has arranged for another course of first aid lectures in French at the French Hospital, Shaftesbury Avenue. It is thought that ladies who hope to work in France will be glad to take advantage of this opportunity.

THE Henry Saxon Snell prize of the Royal Sanitary Institute for 1915 has been awarded to Dr. William Hanna, assistant port medical officer, Liverpool, for his essay on improvements in the sanitary arrangements and appliances suitable on board ship for passengers and crew, and cattle and other live stock respectively. The prize consists of a purse of 50 guineas and the silver medal of the institute.

THE New York State Legislature has passed a bill providing for the training, registration, and licensing as dental hygienists of women who have gone through a course of study at a properly equipped dental dispensary. The new law has been made in view of the bad condition of the teeth of school children in New York, at least 90 per cent. of whom, it is said, need treatment. The dental hygienists may be employed by public institutions and school authorities, and may remove lime deposits, accretions, and stains, but they will not be allowed to perform any other operation on the teeth or tissues of the mouth. Similar enactments are already in force in Massachusetts and Connecticut.

THE President of the Royal Meteorological Society announces that, in accordance with the provisions of the Summer Time Act, Greenwich mean time will continue to be used for all meteorological observations and publications, so as to avoid discontinuity. In addition, however, to the work of regular observers, observations of many meteorological phenomena, often of much interest and importance, are recorded or reported by others. The society asks that any person making such reports will be careful to specify whether the time given is Greenwich mean time or summer time, as the omission of this information may render records valueless.

AT a meeting of the Paris Académie de Médecine, on May 9th, Dr. Taraskevitch presented a report on anti-typhoid vaccination in the Russian army. The union of zemstvos and cities, impressed by the results of this method in Great Britain and France, recommended its adoption, and millions of men have been inoculated. Down to February, 1916, more than 20,000 litres of vaccine had been used. Reports received since then from all parts of the front showed a considerable reduction in typhoid mortality. It has been decided to extend the use of the protective measure to paratyphoid affections and to cholera. About 500,000 soldiers have already been protected against the latter disease, although the method has not yet received official sanction.

THE eighth annual meeting of the Society for the Propagation of the Gospel Medical Missions was held at the Church House, Westminster, on May 10th, the chair was taken by Mrs. Scharlieb, M.D., M.S., who in some opening remarks said that only five per cent. of the population of India received proper medical attendance, and it would be a blot upon the fair fame of our country if means were not taken to relieve their suffering. Dr. Hugh Weir, late of Corea, now secretary of the S.P.G. Medical Missions, said that three doctors and six nursing sisters had taken service with H.M. Forces, and practically all the candidates who would naturally have been ready to sail were similarly occupied. In India the responsibility for the medical work connected with the Cambridge mission to Delhi had been transferred to the S.P.G., the Cambridge Committee contributing to the cost.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) **EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aitology*, *Westrand*, *London*; telephone, 2631, Gerrard. (2) **FINANCIAL SECRETARY** AND **BUSINESS MANAGER** (advertisements, etc.), *Articulate*, *Westrand*, *London*; telephone, 2630, Gerrard. (3) **MEDICAL SECRETARY**, *Medisecra*, *Westrand*, *London*; telephone, 2634, Gerrard. The address of the Irish office of the *British Medical Association* is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

TAXPAYER, a practitioner at A., started a practice at B. in 1912. In 1912 and 1913 this new branch showed a loss, in 1914 it just paid expenses, and in 1915 yielded a profit of £1,000. He has now sold the original practice, and is devoting his whole time to work at B. In the past his income tax returns have been prepared by amalgamating the results at B. with those for his original practice. How should the return be prepared for 1916-17?

On the average of the profits and losses at B. for the three years 1913, 1914, and 1915, as Taxpayer suggests; the average adheres to the business or practice rather than to the individual proprietor. In the same way, the purchaser of the practice at A. is liable on the average profit there, excluding any reference to the past losses at B., even though they were formerly properly included by our correspondent. We may perhaps add that the authorities may require Taxpayer to prepare his statement on the basis of the value of the total bookings at B., on the ground that as the practice there is in effect a new one, the cash receipts fall short of the full income accruing. It should also be borne in mind that any special expenses incurred in starting a branch—for example, cost of fittings, furniture, legal expenses in connexion with leasing new premises, etc.—are of a capital nature, and are therefore inadmissible as professional expenses for income tax purposes.

SIGNING CERTIFICATES.

F. K. wishes to know if other practitioners have had a like experience to his own in signing certificates for young working men who have met with an accident in their work and want compensation. Such certificates, he writes, often contain questions which, it is stated, these young men are to answer in writing themselves. Some of the questions are so simple that no one could fail to understand them, being mere inquiries as to name, residence, age, occupation, and so forth; yet when these certificates are presented to me to be signed I find that not one of the questions have been answered. If I point this out, one young man will say that if I don't write the answers for him he must get a clerk in an office to do this for him and another his father. These young men must have had an elementary school education somewhere. Surely, it must be, not because they cannot write, but because they won't write if they can find somebody more proficient in wielding a pen to write for them! Is this so?

LETTERS, NOTES, ETC.

DYSENTERIC ARTHRITIS.

DR. S. K. CHAUDHURI (Lovett Hospital, Ramnagar, Benares State) writes with reference to Captain Moorhead's note on dysenteric arthritis (April lat, p. 483): I have to record my personal experience. I had a virulent attack of dysentery in March, 1913. It was diagnosed as amoebic by Lieutenant-Colonel H. B. Melville, I.M.S., and Dr. B. N. Mukerje, honorary physician, King Edward VII. Hospital, Benares. This was confirmed by the fact that it was brought under control after nearly a dozen injections of emetine hydrochloride had been made, other remedies having failed. During my convalescence in the third week the metatarso-phalangeal joint of my right big toe became swollen and painful. The onset was quite sudden. I thought the condition to be an acute attack of gout, especially as it is in my family. A course of aspirin, hot fomentations and local antiphlogistic remedies, cleared it up in less than a week. Further injections of emetine hydrochloride were not made for the purpose. I

must mention that I have not had a similar trouble in my joint since then. It did not strike me as a sequel peculiar to dysentery. I cannot recollect coming across any such complication in hospital or private practice.

QUININE AND MALARIA.

DR. JAMES DUNBAR-BRUNTON (Cairo, Egypt) writes: Many times in the course of tropical practice I have been grievously disappointed with the results of quinine treatment administered orally. When the already enfeebled stomach of a sufferer from malaria is still further deranged by quinine in powder thrown into it, and is expected to put forth acid from its glands to dissolve the drug, this is surely to expect too much. A few grains may be absorbed, and the remainder passed through the pylorus interned in mucus and inert to fight. To enlarge the dose is equally unsound treatment. It is better to give frequently a small dose dissolved in weak acid. In 1891 I introduced the use of quinine in suppositories, finding an easy way via the rectal mucous membrane of giving a relatively large dose without upsetting the stomach. But undoubtedly the best way is by the intramuscular injection of quinine bichloride. I have read that it may produce abscesses. Such I have never seen in a long course of many injections. The essential part is to heat the ampoule of the solution over a flame till over blood heat. This is taken into a sterilized all-glass syringe with a long needle, also flame-sterilized. The skin is washed with ether. The injections are given deeply into the gluteal muscles, and no pain is felt afterwards, or alternatively under the shoulder blades between the muscles. The number of injections depends on the amount of malarial infection. With such administration of quinine cures will be effected, and in all cases it gives better results than by intravenous injection. Possibly in the veins the quinine is carried too rapidly to the portal circulation, and possibly made inert. Intramuscularly the absorption goes on more slowly.

HEREDITY.

MR. CASPER L. REDFIELD, of Chicago, has offered the American Genetic Association £200 for evidence as to the transmission of acquired characters. He will pay £40 for evidence that any one of the two or three thousand intellectual men or women of history is the product of an ancestry representing on the average four generations to a century; and £40 for evidence that any one of the two or three hundred intellectually very great men or women of history is the product of an ancestry representing on the average three generations to a century. He will pay £40 for a case "from live stock breeding where the parents made acquirements below the standard, in respect to performance and the offsprings surpassed the parents," and for a case in which "decline in powers of the offspring failed to follow acquirements, in the parents, which were clearly and distinctly below the standard of performance of the breed." He will pay £40 if it can be shown for any group of animals that the amount of improvement or decline in animal powers was not, as nearly as can be determined by actual measurements, exactly proportional to the amount of acquirement by ancestors above or below the normal or standard. Further information as to the method of procedure in these investigations may be obtained on application to the Editor of the *Journal of Heredity*, Washington, D.C., U.S.A.; or to Dr. Redfield, Monadnock Block, Chicago, Ill.

LIGHT BEERS.

LIEUTENANT-COLONEL RUSHTON PARKER, R.A.M.C.(T.) (Professor of Surgery in the University of Liverpool), writes: Ever since I first tasted French beer I have had agreeable recollections of the "bock," dating from a stay of two months in Paris in 1870. But at my last visit in 1914 it seemed to me that there was uniformity in the light, palatable, and cheap beer met with in Paris and at inns and wayside "cafés," as well as in private houses. This beer is to be procured in bottles, closed by a stopper of porcelain and rubber, clamped on with a stout wire grip, easily released or instantly closed again, exactly as we have in this country, each bottle costing a very few pence, and fit for use over and over again. No doubt this beer has resulted from the labours of Pasteur in standardizing the ferment so as to secure an invariable product, possibly controlled by the State. It is greatly to be desired that a similar light, palatable, and cheap beer of uniform quality should be procurable in this country, as it is in France, by all classes of the community whose condition permits the use of such refreshment to quench thirst. The stronger ales hardly quench thirst, but in fact rather tend to promote it.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

ON THE INFLUENCE OF ANTISEPTICS ON THE ACTIVITIES OF LEUCOCYTES AND ON THE HEALING OF WOUNDS.

By C. J. BOND, F.R.C.S., HON. COL. R.A.M.C.(T.),

HONORARY CONSULTING SURGEON TO MILITARY HOSPITALS IN THE NORTHERN COMMAND; MEMBER OF THE MEDICAL RESEARCH COMMITTEE; HONORARY CONSULTING SURGEON TO THE LEICESTER ROYAL INFIRMARY.

PART I.

IN the BRITISH MEDICAL JOURNAL, March 6th, 1915, I recorded some observations which seemed to show that the application of various antiseptics (even in a concentrated form) to the surfaces of aseptic wounds at the time of operation did not prevent primary healing. In the course of that inquiry certain effects on the blood were observed which suggested the desirability of a closer analysis of the problem.

In the first place, if any antiseptic in a concentrated form is applied to the tissues of a wound, efficient drainage of that wound is necessary, and it seemed important to devise some method of drainage which would not only carry off the blood and effused lymph but which would also serve as a trap to catch the emigrating leucocytes. In this way the cells could be recovered for microscopic examination at various intervals after operation, and the influence of various antiseptics could be observed on the behaviour of the leucocytes towards inert pigment particles, and albuminoid and other organic substances introduced into the wound.

A cotton thread of standard thickness and known number of fibres is boiled in water containing powdered indigo in suspension. By this means the thread is uniformly permeated with indigo granules, and can either be dried or kept in the indigo mixture and boiled before use on each occasion. A convenient length of this indigo thread is laid in the wound before suture and one end brought out at one angle of the wound. The usual sterile gauze dressing is applied.

If such an indigo thread drain be removed from an aseptic wound, say twenty hours after operation, and examined in warm normal saline, the fibres of the thread will be found glued together and covered by coagulated lymph containing in its meshes large numbers of living leucocytes, of which a certain percentage will have ingested the indigo granules. The percentage of such indigo-loaded cells will depend on (a) the time the thread has lain in the wound, and (b) the treatment of the wound by antiseptics or other reagents at the time of operation.

If a wound made for the radical cure of hernia or for the removal of varicose veins be so drained under aseptic conditions, and if the indigo thread drain be removed after an interval of twenty-four to forty-eight hours, the portion of the thread which lies in the cavity of the wound will be decolorized. The extent to which this decolorization has been effected affords an indication of the activities of the leucocytes in three directions: (a) Their capacity to leave the vessels and to enter the thread; (b) their capacity to ingest the pigment granules; (c) their capacity to leave the thread and carry the indigo particles with them.

The objection will, no doubt, be made that the decolorization of the thread is not due to phagocytosis, but to the washing out of the pigment granules by the flow of lymph from the wound. The following experiment, however, shows that this is not the case.

Two small beakers were filled, one with normal saline and one with human serum. One end of an indigo thread was placed in each solution, and the other end was allowed to hang over the glass in contact with white gauze; in

each case the fluid was drained out of the beaker into the gauze without washing the indigo out of the thread or depositing it on the gauze (Fig. 1). This shows that the decolorization of the thread drain while lying in the wound is not due to the flow of lymph or blood on to the surface of the wound, and further observations show that it is due to phagocytosis by leucocytes.

We may now ask what becomes of the leucocytes which have ingested the pigment granules. We know that in aseptic wounds the phagocytes do not leave the wound in the form of pus; they must, therefore, after entering the thread and ingesting the pigment, either (1) render the indigo granules unrecognizable by decolorization, or (2) eject the granules after temporary ingestion, or (3) transport the pigment from the thread back to the blood or lymph stream or the tissues. This question of the fate of leucocytes of different kinds, after emigration and phagocytosis, is a point of much interest about which it will be desirable to say more later; meanwhile, having shown that the decolorization of the thread is due to the vital activity of wandering cells, and is not merely a physical question of irrigation by fluids escaping from the wound, we are in a position to use this fact of decolorization and transportation of pigment as a means of testing the influence of various antiseptics on the activities of leucocytes while still living in the wound. The fact that the observations are carried out in the wound itself has considerable advantages. It serves to check observations made *in vitro*, and it is free from some of the fallacies inherent in experiments carried out under more abnormal conditions.

I have made a large number of observations on a considerable number of wounds under strict aseptic conditions in the human subject, and many antiseptics in different degrees of concentration have been tested by this method of the decolorization of the indigo thread. Further, the behaviour of leucocytes in relation to other substances such as egg albumin, serum albumin, starch albumin, glycogen, lecithin, has also been observed in wounds treated with and without antiseptics, though in this paper I propose to deal only with pigment particles. In some cases the wound itself has been washed out before closure with the antiseptic solution; in others the indigo thread alone

FIG. 1.—Drawing from a photograph showing non-decolorization of indigo thread by capillary flow of serum or saline fluid. 1, Serum; 2, saline.

has been saturated before introduction with various antiseptics in a concentrated form. By the first method the tissues from which the leucocytes emigrate are acted on by the reagent, and by the second method the pigment thread into which they pass.

The Effect of Antiseptics on the Decolorization of an Indigo Thread.

Without entering into the details of each case it may be stated in general terms that the application of a fairly strong antiseptic like mercury biniodide 1 in 1,000, or carbolic acid 1 in 20, to a wound such as that made for the radical cure of hernia, or for the removal of varicose veins, does delay to some slight extent the decolorization of an indigo thread placed in it as a drain.

In a wound to which no antiseptic solution has been applied an indigo thread of standard thickness will be almost decolorized in forty-eight hours, and will show very definite sign of partial decolorization twenty-four hours after insertion into the wound. If, on the other hand, the wound be treated before closure with any of the strong antiseptics, or if the thread itself be soaked in any of the same solutions, there will be only slight evidence of decolorization after twenty-four hours, and the thread will still show a blue tinge forty-eight hours after insertion.

The effect of salt solution, both in the 5 per cent. concentration and as normal saline, on decolorization, is about the same as in wounds in which no reagent at all has been used. This occurs when the wound is treated with the solution and when the thread is soaked with it before introduction.

Little difference could be detected (Figs. 2 and 3) in the effect on decolorization between the 5 per cent. salt solution and the 0.9 per cent. solution; and this, indeed, we should expect, because the stronger solution doubtless undergoes rapid dilution by the blood and lymph poured into the wound.

There is some evidence pointing to the fact that different individuals under similar conditions of wound treatment vary in the rapidity with which decolorization is effected; in other words, individual patients vary in the capacity of their leucocytes to (1) emigrate, (2) to ingest foreign particles, and (3) to transport the pigment granules so ingested under the stimulus of injury.

In its clinical aspect this fact is of course familiar to surgeons, and it is no doubt associated with the observed differences in the rapidity with which blood and other effusions are absorbed in persons of different ages and in different states of health. It is a problem of much interest, and will, I hope, be the subject of further inquiry.

FIG. 2.—Drawing from a photograph showing indigo thread after forty-eight hours in wounds treated—1, without antiseptic; 2, with carbolic acid 1 in 20; 3, with salt solution 5 per cent.

FIG. 3.—Drawing from a photograph showing the decolorization of indigo threads soaked in different solutions after forty-eight hours' exposure in the same wound. 1, Thread before introduction; 2, thread without any antiseptic; 3, thread with carbolic acid 1 in 20; 4, thread with salt solution 5 per cent.

pigment is the work of the leucocytes, and is independent of the blood stream and body fluids. In delayed decolorization the delay may be the result of

- (1) Deficient emigration of leucocytes; or
- (2) Impaired ingestion of pigment particles; or
- (3) Failure on the part of the leucocytes to return to the tissues with their loads of pigment.

Before attempting to answer this problem we must first ascertain whether the indigo or other pigment has any injurious effect *per se* on the leucocytes. If an indigo thread drain, removed from a wound which has not been treated with any antiseptic, be teased in warm normal saline and the entrapped leucocytes be watched on the warm stage, the cells which contain pigment granules will be seen to throw out pseudopodia freely, though perhaps not quite so freely as unloaded cells.

The vitality and activity of these loaded phagocytes has been tested in various ways under different conditions. Thus indigo-containing cells were incubated in a saline fluid containing 0.005 per cent. calcium chloride to which carbon particles has also been added as recommended by Hamburger.¹ Although a considerable number of empty cells take up the carbon under these conditions, it is not usual to find many cells which already contain indigo taking up the carbon particles in addition. This point was also tested in the actual wound. Two pieces of gauze, one permeated with indigo and one with carmine, were placed one above the other on a healthy granulating

surface, and the whole covered with protective. The entangled phagocytes were examined in warm saline twenty-four hours later. A large number of cells were found loaded with indigo and others with carmine particles, but only a few cells were seen which contained both kinds of pigment granules.

A composite cotton-thread drain, containing both indigo and carmine particles, was introduced into an aseptic wound and the same result obtained. I am inclined to think that this apparent disinclination on the part of leucocytes to ingest different kinds of pigment granules at the same time in wounds is not due to any injurious effect exercised by the indigo (or the carmine) on the cell, but that it is really the outcome of inertia on the part of the loaded cell, since all inert particles seem to have the same effect in this respect. I say inert particles, because it is necessary to distinguish between such bodies as carbon or other pigment particles around which no digestive vacuole is formed, and assimilable substances like albumin and starch, around which, when ingested, digestive vacuoles are formed.

Indigo-containing leucocytes recovered from an aseptic wound were also incubated in saline fluid containing neutral red in solution as used by Ehrlich, and as recommended by Achard of Paris as a test for living leucocytes. The cytoplasm of the indigo-containing cells takes up the neutral red freely while the nucleus remains unstained. Examined also on Ross's auxetic agar jelly to which atropine sulphate has been added, the indigo-containing cells show active movements.

From these and other observations, both *in vivo* and *in vitro*, we must, I think, conclude that the indigo granules, which are insoluble in the body fluids (except the bile), do not exercise any marked injurious effect on the white blood corpuscles.

Any delay that takes place in the removal of the indigo from the cavity of a wound which has been treated with an antiseptic may be regarded, therefore, as due to the action of that antiseptic solution, and not to any deleterious influence exercised by the indigo on the phagocytes.

We have already seen that in the process of decolorization of the indigo thread three different factors are involved, and the question now arises which of these three factors—Emigration, Ingestion, or Transportation—is responsible for the delay in the removal of the pigment.

Direct observation shows that a thread that has lain in a wound which has been treated by a strong antiseptic solution like carbolic acid 1 in 20 contains apparently about as many leucocytes as a thread which has lain in a wound to which no antiseptic has been applied. Of course, if the raw surface has been cauterized by an escharotic, then the coagulation of the tissue cells and the closure of the blood vessels will prevent the emigration of leucocytes into the cavity of the wound. This, however, does not occur when antiseptics are used in ordinary concentrations under surgical conditions in a recent wound. In several cases of septic wounds, complicated with extensive bone injury, which were being treated by daily irrigation and soaks of chloramine, tampons of indigo gauze were laid in the wound for twenty-four hours. These tampons were found on removal to be covered with pus cells and phagocytes, of which large numbers had ingested indigo granules.

In a case of operation for the radical cure of hydrocele in a young adult, after turning back the tunica vaginalis, the surface of the testis was freely rubbed with pure carbolic acid, with a view to the destruction of the secreting endothelial cells, a rubber tube was inserted down to the testis, and through this rubber tube an indigo thread drain was placed in contact with the cauterized tissues. On examining this thread after removal forty-eight hours later large numbers of leucocytes loaded with indigo granules were found amongst its fibres. Owing to the isolated position of the thread in the rubber tube, the phagocytes which had been carried into it by the flow of lymph had remained in the thread and had been unable to return to the tissues. In this case, although little or no decolorization had taken place, the result was not due to lack of emigration. Quinine has been for long supposed to have a special influence in preventing the emigration of white blood cells. An indigo thread soaked in a 1 per cent. solution of quinine hydrochloride placed in an

aseptic wound was largely decolorized in thirty-six hours; thus, whatever may be the case outside the body, quinine does not seem to prevent phagocytosis of pigment granules in a wound.

These facts all suggest that antiseptic solutions, surgically applied to aseptic and to infected wounds, do not tend to prevent the emigration of leucocytes from the injured tissues; in fact, as we shall see when dealing with organic substances, many antiseptic solutions in moderate concentration stimulate the flow of wandering cells. Neither does the evidence suggest that leucocytes which escape into wounds so treated are unable to ingest indigo or other pigment granules present in the wound.

What does seem to happen is that leucocytes which have so escaped and which have ingested pigment granules are less active in transporting their pigment loads back to the walls of the wound when antiseptics in a concentrated form have been previously applied to that wound.

The Return Immigration of Leucocytes in Wounds.

Metchnikoff showed that leucocytes which had emigrated into the peritoneal cavity to repel bacterial invasion returned in large numbers to the general circulation. Macallum later established the fact that white cells which had wandered into the lumen of the bowel during digestion returned to the portal and systemic circulation. The facts, however, are not so fully known in regard to cells which have emigrated in response to the stimulus of injury either of a mechanical or chemical kind. The problem of the return emigration of leucocytes from wounds has not yet been fully worked out in different tissues, in different kinds of animals, in different varieties of wounds.

In considering this problem it is necessary to distinguish carefully between infected and non-infected wounds.

In infected wounds the throwing off of the dead leucocytes as pus cells is in itself, of course, evidence that large numbers of the white corpuscles which escape from the blood vessels under such conditions do not return to the lymphatic or general circulation. But even in heavily infected suppurating wounds a considerable number of phagocytes do return to the deeper layers of the granulation tissues which line the cavity of the wound.

Thus, if the granulating surface of an infected wound which is showing some attempt at repair, and in which, therefore, the contest between the defensive cells and the pathogenic organisms is not an entirely one-sided one, be dusted with powdered indigo or dressed with a layer of indigo gauze, and if after an interval of some twenty-four hours a small piece of the granulation tissue so treated be removed, sections cut at right angles to the surface will show a number of indigo-containing cells around the new capillaries in the deeper layers of the tissue. If the edge of the granulating area over which the new epithelium is spreading be carefully examined the indigo-containing cells may be sufficiently numerous in the underlying granulation tissue to give a blue appearance to the edge of the wound. Thus, while large numbers of the emigrating cells perish as pus cells, a considerable number survive and return to the tissues and the circulation. Moreover, there is a quantitative relationship between this "return immigration" of cells and the process of repair in the wound. This is seen clinically in the diminishing flow of pus which accompanies successful resistance to bacterial infection and the commencement of healing in a wound. The reduction of discharge is not wholly accounted for by diminished emigration.

The application of antiseptic solutions to granulating wounds, provided they do not cause death of the cells which compose the granulation tissue, does not seem to lessen the number of cells which contain pigment granules, though it does seem to exercise some influence on the number of cells which return to the tissues. A small wick of indigo gauze was laid in a heavily infected wound treated with compresses of eusol; large numbers of leucocytes loaded with indigo were found among the gauze fibres twenty-four hours later.

While this is the condition of things in the septic open wound, the picture presented by aseptic wounds in which suppuration is absent is quite different.

Here there is no throwing off of dead cells. All the cells which have reached the wound area must therefore either return to the circulation and the tissues or perish, and in their turn undergo removal by other phagocytes.

The Route followed by the Leucocytes in Return Immigration.

I have tried to detect the route by which the phagocytes regain the circulation by laying in the floor of an aseptic wound before suture a compound drain composed of a small indigo-bearing thread encased in or applied to one side of a larger thread of wool, as shown in Fig. 4.

On examining such a drain twenty-four or forty-eight hours later the indigo will have disappeared more or less completely from the indigo thread, and the leucocytes which have ingested it now occupy larger or smaller areas of the wool skein.

The degree of decolorization and the lines of retreat of the pigment-bearing cells seem to depend on certain accidental conditions, such as intimacy of contact between the indigo thread and the living tissues in the floor and sides of the wound. If the indigo thread lies, so to speak, free in the cavity of the wound imbedded in coagulated lymph, then the movements of the phagocytes are restricted, and they may only reach that portion of the wool skein which lies in direct contact with the indigo thread. Where the indigo thread is in direct touch with the living tissues the pigment-bearing phagocytes seem to return directly to the tissues in preference to entering the meshes of the wool fibres, though these are, of course, crowded with freshly emigrating cells which have not yet reached the indigo granules.

Further, the nature and vascularity of the tissues with which the pigment thread lies in contact also exercise an influence on the return flow. For instance, fatty tissues do not offer a favourable site for return immigration. The fibrous aponeurosis of the external oblique (in hernia wounds), if roughly handled and deprived of its feeble blood supply by gauze stripping, does not afford as favourable a clearing ground for rapid decolorization as the more vascular subcutaneous tissue.

This composite thread drain can also be used to test the effect of antiseptic solutions on this current of return immigration.

Fig. 5 shows cross sections of two such drains. In No. 1, from an untreated wound, the phagocytes have removed the indigo from the indigo thread and deposited it in the wool skein. In No. 2, from a wound washed out with mercury binioidide 1 in 1,000, the cotton fibre has undergone little or no decolorization and the wool skein is still white and contains only a few indigo-laden cells. In this case the delayed decolorization of the thread in the wound treated with the antiseptics is not due to failure in either emigration or ingestion because the indigo thread is crowded with loaded leucocytes (Fig. 6).

I also tried to test this problem of the route followed by the phagocytes in return immigration and the influence of different tissues upon it by laying an indigo thread in one angle of the wound and a white cotton thread of like size but free from pigment in the other angle. When examined twenty-four hours later, very few pigment-laden leucocytes were found in the white cotton thread. The phagocytes seem to take the shortest route to the tissues as far as the coagulated lymph and blood which occupies the cavity of the wound will allow, and the cells do not seem to make their way to other foreign substances in other parts of the same wound. This is in harmony with the previous observations that leucocytes which have

FIG. 4.—Diagram showing arrangement of compound thread. 1, Indigo thread; W, white wool skein.

FIG. 5.—Drawing from photograph of cross sections of composite indigo and wool drain after removal from wound (+ 5 diam.). 1, From untreated wound, shows decolorization of indigo thread and deposit in wool drain. 2, From wound treated with mercury binioidide 1 in 1,000, no decolorization of indigo thread, no deposit of pigment in wool drain.

already ingested one kind of pigment do not seem very active in ingesting a second variety. In view of the clinical phenomena associated with the spread of infection and the inflammatory reaction which accompanies infection, I also attempted to ascertain whether any extensive migration of pigment-laden cells occurs in the tissues which surround the wound, or, more accurately, whether, having emigrated and ingested foreign substances at the seat of injury, and having returned to the tissues, these pigment-laden phagocytes re-emigrate at the site of a neighbouring wound. To test this point an indigo-thread

FIG. 6.—Drawing from a photomicrograph showing phagocytes containing indigo granules lying on and around a cotton fibre from the wound in Fig. 5, 2 ($\times 500$). It illustrates the fact that absence of decolorization is not due to failure in emigration or ingestion on the part of the leucocytes.

drain was placed in one incision in a case of operation for varicose veins, and a white cotton unpigmented thread was placed in a neighbouring incision a little above the first. When removed, twenty-four hours later, no indigo-bearing cells were recovered from this white thread in a neighbouring wound.

Mention has already been made of the fact that no extensive ingestion of both kinds of pigment by the same cells occurs in two superimposed pieces of indigo and carmine gauze placed on a granulating wound. The same is true of aseptic wounds. Thus, a compound pigment thread containing both carmine and indigo particles removed from such a wound contained both indigo and carmine-loaded cells, but few cells carrying both blue and red granules.

Further observations are needed, but it seems probable that the "return immigration" of phagocytes is not entirely a question of chance, but is subject to a chemotactic influence just like outward emigration. This does not, of course, mean that the element of chance does not play a large part in the movements of wandering cells in both the outward and the return journey.

Jennings and others have shown that the response of the amoeba and other protozoal organisms to attracting and repelling substances, and to physical stimuli, largely consists in movements of trial and error. The organism assumes various experimental positions along a line of least resistance, and this is probably true of the white blood corpuscles in man.

The Influence of Antiseptic Solutions on Return Immigration.

I have already spoken of the effect of a previously applied antiseptic on the process of decolorization of the indigo thread, and on the movements of the pigment-laden leucocytes in the composite cotton and wool thread. I have shown that the application of a strong reagent like pure carbolic acid to the surfaces of a wound made for the radical cure of hydrocele does not apparently reduce the numbers of wandering cells which crowd into the cavity of the wound, or the ingestion of the pigment by these cells. Evidently the effect of antiseptics used surgically does not check the emigration of leucocytes or their phagocytic activities as far as pigment is concerned—in fact, as we shall see later when dealing with organic substances, emigration is in some cases accelerated. It is, however, quite possible that emigration and phagocytosis may be going on freely, and yet the healing of such a wound may be prejudiced by the accumulation of the phagocytes in the cavity of the wound.

The delayed decolorization of the indigo thread which occurs in wounds which have been treated with certain reagents is probably partly due, therefore, to delayed return immigration.

Return Immigration in Suppurating Wounds.

The extent to which phagocytes which have flowed on to the surface of a suppurating wound can re-enter the tissues or the circulation depends upon, and is an indication of, the degree of injury which these wandering cells have sustained in their struggle with the pathogenic organisms established in the wound.

A certain amount of return immigration probably takes place on all granulating surfaces, as in all injured areas, with the exception perhaps of those wounds in which the infecting organisms have obtained complete mastery—a condition shown clinically by the cessation of discharge, together with signs of general toxæmia. Even in heavily infected granulating wounds, if a portion of the granulation tissue be excised after the surface has been dressed for two or three days with indigo, sections cut at right angles to the surface will reveal the presence of indigo-laden cells around the capillary loops in the newly-formed tissue. This occurs independently of the kind of antiseptic used provided that it is not strong enough to kill the cells.

I have attempted to investigate this question of the effect of antiseptic reagents on return-immigration in suppurating wounds experimentally in animals. Two small skin flaps were raised one on either side of the spine in the lumbar region in a guinea-pig. A piece of white gauze was laid in each wound so formed, and the flaps resutured over the gauze. Three days later (under an anaesthetic) the flaps were again raised, and indigo-saturated gauze was substituted for the plain gauze; on the right side no antiseptic was used, but on the left side the granulating surface was washed with carbolic acid 1 in 20, and the indigo gauze was soaked in the same solution before insertion in the wound, which was dressed later with the same lotion. The animal was killed two days later, and both wounds with the surrounding tissues excised and hardened in formalin. Sections embracing the entire thickness of the wounds show that indigo-laden phagocytes have wandered freely into the granulation tissue on both sides. In the wound to which the antiseptic had been applied the flow of pigment was less regular round the margins of the wound. It had not penetrated so far into the tissues except at one part along the aponeurosis between the subcutaneous and muscular tissues at the deep end of the wound, where possibly the antiseptic had not penetrated so freely.

Pus—Not Only Composed of Dead Cells.

Various samples of pus from heavily infected wounds have been tested from the point of view of the capacity of the pus cells to ingest foreign particles *in vitro*. Starting with the preconceived idea, which I think is still shared

FIG. 7.—Drawing from a photomicrograph showing "pus" from a case of peritonitis incubated with indigo for eight hours. It contains a single field (one-twelfth water immersion and A ocular). Several "pus" cells are loaded with indigo granules and masses. P, Pus cell containing indigo; c, indigo escaped from ruptured cell.

by some surgeons, that pus is always composed of "dead" cells; I have been impressed with the fact that very few samples when incubated with pigment granules in normal saline have failed to give evidence of some capacity of ingestion on the part of a certain number of the cells of which the liquid is composed (Fig. 7).

If we regard capacity to flow round and ingest foreign particles as evidence of vitality then we must conclude that while most of the cells in pus from infected wounds are dead cells, yet a certain proportion are still living and capable under favourable conditions of active phagocytosis. This observation on the behaviour of pus cells *in vitro* is in harmony with the previously recorded activities of pus cells in the actual granulating wound. The proportion of living to dead cells bears some relation to the number and virulence of the infecting organisms and the digestive changes in the liquor puris.

In samples of pus taken from wounds infected with pyogenic organisms which show some attempt at successful reaction, the amount of carbolic acid in normal saline necessary to inhibit the ingestion of carmine particles by the pus cells when incubated for twenty-four hours is somewhere between 1 in 640 and 1 in 1,000.

This applies to pus removed from a wound and incubated with pigment *in vitro*. When, however, the pus cells are brought in contact with the indigo particles *in situ*, and are allowed to collect upon a layer of indigo-saturated gauze laid on a granulating surface and covered with protective, the incubation is carried out in the wound and a much larger number of indigo-containing cells can be recovered from the gauze. The proportion between living and dead cells, as judged by the test of ingestion, depends upon the healthiness of the wound. The strength of the acid carbolic solution necessary to inhibit the ingestion of pigment particles by the cells under these conditions must be judged by another standard. If indigo gauze soaked in normal saline be used as the control, then it will be found that ingestion of pigment goes on freely in gauze which has been soaked in acid carbolic solution, 1 in 60, before application to the wound. This method of testing the ingestive capacity of pus cells by incubating them with pigment granules in the wound itself affords a striking proof of the fact that many samples of pus contain considerable numbers of living leucocytes. It also affords a means of ascertaining the healthiness or unhealthiness of any wound, and of testing the effect of different antiseptic solutions on the life and activities of the leucocytes in the wound itself. Of the many factors which affect the vitality of leucocytes in a wound one of the most important (apart from the number and virulence of the infecting organisms) is the length of time which elapses after the cells have emigrated from the circulation and during which they have been exposed to the unnatural environment of an open wound. It is the recently emigrated cells which seem to retain the capacity to ingest foreign particles, and this fact bears on the very important problem of the efficient drainage of wounds. The object of drainage should be not only to provide for the escape of dead cells, but to further the emigration of living phagocytes.

We know that laudable pus (in other words, pus containing living phagocytes) indicates healthy activity in a granulating wound. It is possible that (in the absence of aseptic human leucocytes), if some means could be found to kill the ingested organisms without injuring the phagocytes, and to wash the cells so treated free from contaminating liquor puris, such revitalized pus would form a useful dressing for suppurating wounds.

The Difference between Suppurating and Non-suppurating Wounds.

Apart from the all-important factor of the presence or absence of infecting organisms, the differences between a suppurating and a non-suppurating wound are chiefly differences of degree and not of kind. We know that the tissues and the spaces between the tissues in the primarily healing aseptic wound are crowded with living phagocytes capable of ingesting both foreign particles and dead cells. We have also seen that a considerable number of the cells which compose the purulent discharge from a suppurating wound are also living cells capable of ingesting foreign material and acting as phagocytes. Emigration and capacity for ingestion are therefore factors common to both kinds of wound. The main difference between them lies in the fact that, while the proportion of phagocytes which find their way back to the tissues or the circulation is large in the primarily healing wound, it is relatively small in the suppurating wound. The degree of return immigration constitutes, in fact, the main distinction between the aseptic and the suppurating wound.

SUMMARY AND CONCLUSIONS.

I am fully conscious of the incomplete character of these observations. No attempt has been made to differentiate between the different varieties of phagocytes. Although this point has not been entirely lost sight of, the overwhelming numerical superiority and the greater importance of the polynuclear leucocytes in wound reactions has led me to limit my remarks at present to this group.

Further, the different ways in which different tissues and different organs respond both to different kinds of infecting organisms and to different kinds of antiseptic solutions is a wide and important subject. The work required to elucidate the method of such a comparatively simple reaction as the deportation of foreign pigment in the brain, liver, and other organs is very considerable, and must form the subject of further inquiry.

It will no doubt appear to many that the all-important factor of the infecting organism has not received adequate attention. The problem of wound reaction and wound treatment is, however, so enormous that some subdivision of the subject is absolutely necessary, and in this paper I have tried to deal only with the effect of various antiseptic reagents on emigration, phagocytosis (or ingestion), and return immigration of leucocytes when carrying pigment granules.

The outcome of the inquiry seems to be that antiseptic solutions in moderate degrees of concentration exercise less influence over emigration and phagocytosis than many surgeons have supposed. There are, however, reasons for concluding that antiseptics do exert a considerable inhibitive effect on the return immigration of living phagocytes. This aspect of the subject should, I think, be borne in mind in descriptions of the effect of different antiseptics in killing off pathogenic organisms in pus and other liquids *in vitro* and on the sterilization of wounds.

Provided efficient drainage is ensured, the surgical application of most antiseptic solutions does not apparently materially prejudice the defensive activity of the tissues in either infected or non-infected wounds. If it can be shown that the use of antiseptic reagents does at any stage diminish the numbers or inhibit the activities of pathogenic organisms, not merely *in vitro* but in the actual wound, then, although these reagents do undoubtedly cause the death of a certain number of body cells and prevent others from again reaching the tissues, this is a small matter if the invading organisms are at the same time materially diminished in numbers or in offensive capacity. It is the continuous and increasing effect of infection which is so inimical to healing. The occasional death of even large numbers of phagocytes is well borne if time be given to make up the loss. It is the strain of continued cell multiplication and the providing for the removal of organisms and cells that have perished in the struggle that tells.

The experimental introduction of pigment particles into a wound also throws a valuable sidelight on wound infection. In a general way the transportation of the pigment follows the same routes and the same lines of least resistance as those traversed by infecting organisms. The same peculiarities are apparent in the permeation of tissues and organs by the pigment granules. The liver, the spleen, the kidney, and the brain each presents its own special problem in emigration, phagocytosis, and return immigration.

Bearing in mind the fact that pigment particles are incapable of intrinsic movement, or multiplication, or growth, any transportation of pigment in so far as it is not due to currents in the lymph or other fluids bathing the wound, must be due to the action of living cells.

It is interesting to find that the route taken by the pigment in the tissues generally coincides with the route taken by the infecting organisms; thus infection and return immigration roughly coincide. Several side issues of considerable interest arise out of this problem of the return immigration of phagocytes. Unless the ingested cocci and bacteria which are carried into the tissues by the phagocytes on their return journey are killed, or sufficiently attenuated to render them incapable of further growth, they may start into renewed activity on the death and disintegration of the cells which contain them. It is possible that some cases of recrudescence local sepsis may owe their origin to this cause.

The extent to which intrinsic motility and capacity for continuous growth enable pathogenic organisms to establish themselves in the walls rather than in the cavity or on the surfaces of a wound, no doubt varies with different organisms and in different tissues. The fact, however, that phagocytes are constantly transporting organisms from the cavity or the surface to the tissues which form the walls of a wound means that any adverse influence acting on these loaded cells on their return journey calculated to interfere with their power of retaining and digesting these ingested organisms is a source of danger. It is possibly in this way that antiseptic solutions act prejudicially when used too continuously or in a too concentrated form.

In connexion with this investigation I wish to acknowledge valuable help received from Captain Clare, R.A.M.C., and Sergeant Crane at the Pathological Laboratory of the 1/5 Northern Hospital, and from the resident staff, and R. Bertram, laboratory assistant, at the Leicester Royal Infirmary.

III. THE SOLDIER'S FOOT AND THE TREATMENT OF COMMON DEFORMITIES OF THE FOOT.

BY

LIEUTENANT-COLONEL ROBERT JONES, CH.M.,

F.R.C.S.I. (HON.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

(Continued from page 753.)

PART III.

HAMMER-TOE.

HAMMER-TOE is a deformity which usually affects the second toe, though it is common to find slighter degrees of the condition in other toes. It consists of flexion of the proximal interphalangeal joint and dorsiflexion of the metatarso-phalangeal joint (Fig. 1). The prominent knuckle of the proximal interphalangeal joint chafes on the upper of the boot, while the tip of the toe is pressed on the sole. Painful corns naturally develop at these points of pressure, making the man unfit to march.

FIG. 1.—Hammer-toe.

The causes are numerous: sometimes the deformity runs in families, but the commonest cause is the crowding of the toes in ill-fitting, badly designed boots. Hence it is common to find hammer-toe associated with hallux valgus.

Treatment.

In the adult operative procedure is indicated if we are to produce a quick and lasting recovery. Neither amputation of the toe nor an attempt at pseudo-arthritis of the proximal interphalangeal joint should ever be undertaken. Amputation should not be done, because the absence of the second toe increases the tendency to the production of hallux valgus, and often leads to a second disability more serious than the original hammer-toe (Fig. 2).

FIG. 2.—The disability produced by amputation of second toe.

Some surgeons, when operating to correct the deformity, leave the articular cartilage on one side of the joint in order to obtain a new joint. My experience is that this is followed by recurrence so frequently that the operation should be condemned as uncertain.

Operation.

The operation found most uniformly satisfactory is a wedge-shaped excision removing the articular cartilage on

both sides of the joint, so as definitely to ankylose the joint in extension. An oval piece of skin, including the corn, is excised over the prominent knuckle. A wedge, base upwards, including the joint, is then excised, of sufficient size to allow the toe to be straightened (Fig. 3). The flexor tendon is divided by tenotomy. The skin incision is then

FIG. 3.—Wedge excision of joint for hammer-toe.

stitched so as to leave a transverse linear scar. The toe is fixed down to the toe-splint shown in Fig. 4, and the patient walks about, still wearing the splint inside his boots, for some weeks, to make sure that solid ankylosis occurs without any return of the deformity.

FIG. 4.—Splint for hammer-toe.

DISPLACEMENT OF THE LITTLE TOE.

A displacement of the little toe, similar in nature to hallux valgus, frequently occurs, usually as the result of wearing boots which are too tight and too pointed. Occasionally the condition is congenital. The toe is displaced inwards either over the dorsal or under the palmar aspect of the fourth toe. In either position it is subjected to undue pressure in any ordinary boot, and therefore becomes painful.

Treatment.

This condition is very troublesome, and when it occurs in a soldier an operation is essential. The treatment which may be applied successfully in children has no place here, as the structures have become so contracted, especially the skin, that tenotomies, excisions, or simple splintings are wholly inefficient. Amputation of the toe is simple and effective in most cases, especially if no callosities have formed under the metatarsal head. In amputating it is advisable to make an ample flap to obviate the result of subsequent contractures and to secure a lax fleshy covering for the bone. If a callosity has formed, no pressure should be allowed upon that area until by rest and treatment it has become soft and normal. If the head of the bone is arthritic and the condition is complicated by exostoses or irregularities, these should be pared away. Only in very exceptional circumstances should the head of the metatarsal be removed, for, as pointed out in a previous article, this forms one of the points of support in the foot on which a soldier's marching powers depend.

METATARSALGIA.

Metatarsalgia is a peculiarly painful disability of the foot associated with flattening of the transverse arch. The characteristic pain is usually felt in the fourth metatarso-phalangeal joint, frequently in the third, and less often in the second. The pain is variously described as a sharp stab, a burning pain, or as if the patient was "stepping on a red-hot pea." The pain may come on suddenly as the patient is walking in the street, and cripple him, so that he has to hobble into a shop and get his boot off. The device adopted by most patients to obtain relief is to grasp the metatarsals in the hands and squeeze them so as to restore the transverse arch. In more chronic cases the affected toe becomes glazed and shows signs of trophic disturbance, while in some cases there is complaint of severe pain shooting up the leg.

Morton in his original description attributed the pain to pinching of the digital nerves between the metatarsal heads. The fact that relief is obtained by squeezing the metatarsal heads casts doubt on the truth of this. I described the condition fully in 1897, and stated that,

as the result of the study of dissections and frozen sections, I had come to the conclusion that descent of the transverse arch and consequent pressure on the nerves in the sole was the real cause of the pain.

Diagnosis is easily made by the characteristic tenderness elicited by pressing the offending joint between the finger and the thumb. In addition, obvious flattening of the transverse arch is usually present, and the fatty pad under the heads of the metatarsals is absorbed by the pressure of the descended arch, so that the "ball of the foot" feels unnaturally thin, and there are corns in the sole under the unusual points of pressure. The condition is therefore to be regarded as directly connected with overstrain of the foot, and is consequently associated with flat-foot.

Treatment.

Immediate relief can nearly always be given by removing the pressure of the body weight off the heads of the metatarsal bones by a bar behind them (Fig. 5).

FIG. 5.—Treatment of metatarsalgia. Bar on sole of foot behind the heads of the metatarsal bones.

The effect of this is to carry the body weight on the necks of the metatarsals. The heel of the boot should also be raised one third of an inch on the inner side, as for ordinary flat-foot. A band of strapping round the bases of the metatarsals to prevent spreading also helps. These measures, combined with exercise of all the small muscles of the foot to restore the arch, and massage to relieve the pain and improve nutrition, will suffice to cure all early cases in the space of a few weeks.

The patient should then be warned against wearing narrow boots, which impede the free play of the fore part of the foot, and conduce to atrophy of the muscles of the foot from disuse.

In cases which have lasted for some time these measures do not suffice for a cure, though they give some relief.

Operation.

More drastic measures are required for the soldier's foot. Removal of the head of the offending metatarsal through a small dorsal incision completely relieves the condition in ninety per cent. of cases, even when the crippling effects have lasted a long time, and the patient is suffering so much that he asks for amputation of the foot. In the remaining cases it gives enough relief for the patient to be made comfortable with a bar across the sole of the boot.

After-Treatment.

The bar on the sole of the boot and crooked heel, already described, should be employed as an essential part of the after-treatment. The patient may then walk during the whole period of convalescence without injuring the site of operation, and so exciting new inflammatory changes.

PAINFUL CONDITIONS ABOUT THE HEEL.

The painful conditions about the heel most commonly met with may generally be traced to one of three causes:

1. Injuries or strain about the insertion of the tendo Achillis.
2. Spurs of bone and adventitious bursae under the os calcis.
3. Osteitis and periostitis from direct injury of the os calcis.

Injuries and strains about the insertion of the tendo Achillis are marked by pain about the back of the heel which is aggravated by walking and relieved by rest, but the pain recurs again if the patient is tempted to take exercise. The condition may be divided into three types:

1. *Tenosynovitis*, in which there is swelling due to effusion within the tendon sheath. This swelling extends some distance up the tendon, and is both palpable and visible.

The treatment is counter irritation, firm bandaging and rest. When the acute stage is passed the patient may be allowed to walk limited distances with the heel of the boot raised $\frac{1}{2}$ in., so as to relax the tendon and diminish the strain. If the condition tends to

become chronic, the actual cautery may be used with great benefit, especially in the form of the heated needle.

2. *Bursitis* of the bursa under the insertion of the tendon into the os calcis. This is diagnosed by localizing the tenderness at the site of the bursa and by detecting a small area of fluctuation.

Treatment.—Relax the tendon by raising the heel $\frac{1}{2}$ in. Apply a band of strapping round the leg above the malleoli to act like the wristlet worn by workmen who have strained a tendon at the wrist. The patient should be instructed to walk a little every day, but should not be allowed to do an indefinite amount of walking; this is one of the difficulties connected with letting soldiers out from hospital on pass.

3. *Periostitis* at the site of insertion of the tendon, due to strain of the insertion.

The diagnosis is made by localizing the tenderness on pressure a little lower down than in the case of bursitis, and by the absence of deep fluctuation in the bursa beneath the tendon. The treatment by rest is the same as for the preceding condition.

Both these last-mentioned conditions may be present simultaneously and become chronic. The best treatment then is first to puncture the bursa or the inflamed area of periosteum several times with a hot needle. The process is exactly that known to the farrier as "pin-firing." The effect of this is to excite an active vascularization of the part, after which repair takes place more rapidly if the rest treatment is carried out.

Further, cauterizing a patient's heel deters him from wearing a boot and going out for too long walks, and gives the deep lesion an opportunity to recover while the surface blister is healing.

Irregular fibrous masses are sometimes noted in the Achilles tendon. These are usually the result of partial ruptures, and if large and persistently painful they should be removed.

SPURS OF BONE UNDER THE OS CALCIS.

Spurs of bone running forward into the plantar fascia or

short muscles of the sole are frequently seen in skiagraphs (Fig. 6). They often cause no symptoms. On the other hand, if the patient accidentally jumps on to a stone and bruises the periosteum over one of these spurs, it may become enlarged, or an adventitious bursa may develop under it. After this, the patient feels pain every time he puts his heel on the ground, and in the course of a long march.

FIG. 6.—Spur of bone under os calcis.

Treatment.

Make an incision along the side of the foot and gouge away the spur and tissue round it to make sure of clearing out the bursa and any chronically inflamed periosteum. The incision should, of course, not be made in the sole, as a scar in these regions is often itself the cause of trouble.

Osteitis and Periostitis.

Osteitis and periostitis of the os calcis often arise from bruising of the bone by a jump or fall from a height, or by injury due to gunshot. There may be no gross fracture, only some crumpling of the lamellae, which may be seen in a good skiagraph. When a fracture occurs, the disability is, often due to bony irregularities on the under surface of the bone.

Treatment is often unsatisfactory, and if the bony masses are felt in the sole under the heel they should be freely removed. Palliative measures are of no use in the case of a soldier; and one may state as a general proposition that a soldier with a badly-fractured astragalus or os calcis will not again be fit for service.

THE City Council of Boston has issued an ordinance establishing zones of silence in the neighbourhood of hospitals with fifty or more beds. Foot passengers, drivers of vehicles and street cars, and operators of motors are warned not to make any unnecessary noise within these zones.

12. A most interesting case is that of certain railway engineers. These men lived together in a large room, changed and bathed every week, and had been at the front for three months. Not a single louse was found upon them.

It is suggested, by nature of the work among oil, that to this factor is partly attributed the freedom from the pest.

13. By reference to Graph No. 2 it will be seen that there is a break after 130. This produces the result that nearly 5 per cent. of men are what may be termed "maximum cases." These "horrible examples" showed the number of lice upon each man to be 168, 180, 190, 376, 400, 552, and 895. Another shirt held 1,355 lice and 4,260 eggs, while another showed 10,428 lice approximately and 10,253 eggs approximately. Reference has been made already to another extreme case.

"Lousing" in the Trenches.

The object of this inquiry was to ascertain from the witness of the men themselves what were the results of their self-searching for the pest. A certain division had served at two parts of the line, and the men from eleven different units were interrogated. Their average spell in the trenches had been about twelve days. The inquiry shows: (1) The average daily catch of the soldier was 8 at one sector and 9 at another; (2) the catch varied between 9 and 60; (3) that, from some source or sources, the man in the trenches is liable to a persistent daily visitation which insists on daily attention. The bag, as a general rule, is mixed, young and adults being obtained. Without encroaching on the section "Dissemination," it may be remarked that the main source of the young lice is undoubtedly the eggs on the clothing of the man himself. This accounts in part for the daily persistency of infestation. The difficulties of self-searching are great, and may be responsible for the overlooking of some of the large adults, but the constant recurrence seems to indicate that other sources, external, supply the large specimens.

It would be expected that soldiers living in the bare trench, where no dug-outs exist, would be more free from lice than soldiers living in dug-outs. The contrast is afforded in the example of the division under inquiry. At one time of the year the men were in bare trenches at one part of the line, and six months after they occupied dug-outs at another part. Men, however, were lousy to practically the same degree at each point. At the first place it was impossible to change clothing, and at the second they lived in close contact in dug-outs.

Lice and Dug-outs.

One of the most prevalent terms is "lousy dug-outs." Before conducting examinations in the first line of trenches, the impression obtained from conversation with soldiers—and others, too, of a more critical turn of mind—was that dug-outs were swarming with lice. The most comfortable form of dug-out is that which is completely boarded. More primitive types exist in which less wood is present and the floor is of earth. Five dug-outs of the boarded type were carefully searched. Included was a large one occupied by six machine gunners. Skilful assistance in this search was given by a stretcher-bearer, an ex-schoolmaster. The search in each dug-out usually lasted an hour, and was conducted in daylight with as much extra light as was possible to obtain from candles. In two cases the boards composing the floor were removed and carefully scrutinized, as were cracks and corners, with the fluff lurking there; kits, greatcoats, and sandbags were subjected to a like search. *In no case was a single live louse discovered.* Eight dug-outs with earth floors, at another part of the line, yielded a like result.

By reason of the military situation a most interesting experiment was terminated before culmination. The stretcher-bearer and the writer took measures to secure freedom from the pest. They slept with less clothing than worn by men in the line, but using two blankets, for two successive nights in a boarded dug-out newly vacated by three lousy soldiers. The conditions, therefore, were most favourable for picking up any lice present. After the first night an examination of the clothing and blankets gave a negative result. The night of that day the clothing and blankets were examined, as carefully as candle light permitted, and seemed clean, but the following morning the assistant's linings showed one louse and one flea.

From one point of view, if this typical dug-out had been really a "lousy dug-out," it is reasonable to conclude that more lice would have been found on the clothing. It is quite possible, too, that the one louse found may have been obtained during the daily duties among the men and overlooked at the night examination, owing to the bad light.

It is not denied that lice may be present in dug-outs, but these evidently play a minor part in the harbouring and disseminating of the parasite.

Lousiness of Material.

Blankets.—In this connexion only two typical cases out of ten examinations are cited. The blankets of twenty-four infantrymen were searched. Their regiment had an average lousiness per man of 31.4, and had spent twelve days of the early autumn in the trenches. The blankets had been used for five days. Many were found free from lice. The highest number found on a single blanket was 6 (alive), and the total number of lice found was only 20 (alive), the average, therefore, being 0.8 per blanket. In the second example twenty-five blankets were examined in the winter, after being away from the men for about four days. Ten were free from lice; the highest number alive on a single blanket was 2, and the highest number dead was 4. The total numbers were 5 alive and 21 dead, the average, therefore, being about 1.0, dead or alive. The degree of infestation of the unit is not known, but is certainly no less than at any other time of the year. In sporadic cases blankets have been found exceedingly verminous, holding 20, 60, and more lice. This condition was always correlated with the fact that the men using them were very unclean. Blankets, therefore, are of minor importance as harbours and centres of dissemination.

Straw.—Straw sufficient for three men was placed in a corner of a room, infested with 535 lice, and left for nearly four and a half days. At the end of this time three clean men slept for three successive nights upon it. After the first night the total number of lice from all the men was 18, the second night 4, and the third night 7. The experiment shows that infested straw may be sufficiently lousy at the end of seven days to infest men using it. A similar experiment, using 1,000 lice and leaving the straw five and a half days, showed 2 after one night's use, 2 after the second night's, and none after the third night's. Straw was placed as above, and infested with 500 lice. After three hours, to allow the insects to scatter and accommodate themselves, N.C.I. powder was dusted on the straw. After eight hours three clean men slept upon it. Next morning the total number of lice from all three men was 7 alive and 6 dead. The straw was retreated, and after the second night, with two men using it, no lice were picked up. The experiment demonstrates the efficiency of N.C.I. as a swift preventive of infestation from straw.

Paillasses.—Three paillasses, infested with 325, 500, and 500 lice respectively, were examined after eight days, and live lice were still found.

From the characteristic disinclination of the louse to leave clothing, it does not seem likely that straw will ever become very much infested.

DISSEMINATION OF THE PEST.

Three sources of infestation may be conveniently named: (1) Living places—dug-outs, billets, bivouacs; (2) material—blankets, straw, beds; (3) the soldier, with his clothing and kit.

Living Places.

Only the dug-out is discussed, but the same remarks apply to billets and bivouacs.

The main problem presents itself thus. Men state confidently that they go into the trenches clean, and in a few days find themselves infested. The general statement goes, "the dug-outs are lousy." It will be well to examine this critically.

If it may be assumed that a "lousy dug-out" was one which harboured twenty live lice, it is very unlikely that careful trained observation would not discover a single live specimen in thirteen dug-outs.

A man may have lice upon him all the time, and yet not feel any discomfort. Such men, it has been found, always

believe themselves to be clean, and generally declare it aggressively. Another unobtrusive but most important source of danger is the presence of eggs upon the clothing. There is the probability also of an unclean comrade.

The dug-outs with most unenviable reputation are those which are large and accommodate most men. Certain dug-outs—those of officers and senior non-commissioned officers—are frequently occupied by only one individual, and in these cases lousiness is not common. These living conditions, giving greater opportunities for change of clothing, for physical cleanliness, cleaner companionship, and often comparative isolation, are the converse of those of the men.

An important observation is the preference of the insect for remaining on warm material. This renders the probability of infestation from the soil very small, though, as has been pointed out, lice may endure surface soil conditions for seven days. In so doing it is quite possible for infestation to come from the ground. The chance of this, however, is very remote.

When a dug-out has been emptied of all kit, sandbags, etc.—such usually being the case when one unit makes way for its relief—most of the lice are removed also with that unit.

The weight of the evidence, therefore, goes to show that the dug-out itself is not an important factor in the harbouring and dissemination of the pest.

Material.

Previously mentioned facts show that, in exceptional cases, infested blankets may be centres of dissemination, but that, as a general rule, they are a minor source of dissemination.

From the preference of the louse for clothing worn next the skin or such clothing discarded, and the absence of lice upon blankets and empty sandbags used as bedding, it seems fair to deduce that straw and paillasses, which are colder habitats for the insect, will not be tempting places of sojourn for them.

The Infested Soldier.

Infestation from dug-outs and blankets being very slight, there remains the soldier himself. Concerning the conditions of the soldier, it will be well to recall to mind that 95 per cent. of soldiers who had seen six months' service were found lousy; that the average number of lice per man was twenty; that 5 per cent. (or 50 to a battalion of 1,000) were dangerous carriers, each bearing between 100 to 300 lice. Also, take the condition of a unit ready for the trenches after its few days' rest. During this time men are supposed to bathe and obtain a change of underclothing. Certain men have not bathed or changed owing to duty, or through shirking, and most have not had the outer clothing treated; that is, practically every man is still a carrier, while a certain few are likely to be in a worse condition.

Dissemination may possibly occur by three methods—accident, contact, and instinct on the part of the insect. In the first instance, the ordinary actions of everyday life, dressing or undressing, may dislodge the insects from the inner clothing to the outer, or from the outer directly to the clothing of a comrade, or indirectly via blankets or kit. In the case of contact, transference may be effected during close proximity for a short time, as in the case of doctor and patient, teacher and scholar. More favourable, and, to the mind of the writer, the principal conditions of transference are the long periods of proximity, engendering warmth and consequent movement of the lice, as when men are compelled to sleep closely together. The instincts of detecting and selecting the host seem at best too feeble to account for much dissemination.

The natural question is often asked, "How did the parasite first gain a footing in the army at the front?" In answer to this, the writer recalls the first day of mobilization, the pouring in of reservists to the barracks, among them many from the verminous slums, the mingling of mufti and khaki in the crowded rooms, and soon, with scant opportunity for obtaining anew the smartness and cleanliness of army life, the hurried dispatch to the seat of war. Once the louse was brought to the Expeditionary Force, the absence of facilities for washing and changing clothing, and the crowding together of troops, gave the parasite every condition favourable to lodging, feeding, multiplying and spreading.

METHODS OF PREVENTION AND DESTRUCTION.

Treatment of Cases Naturally Infested.

The condition of men was noted by the method already explained. The effects of various preparations were taken after one day, in most cases, and in a few cases for longer periods.

Treatment of Cases Artificially Infested.

Artificial infestation was carried on by taking a known number of lice from a newly-discarded shirt, and placing them on different parts of the body—that is, down the legs of the trousers, and inside the back and front of the shirt. After two to six hours—time sufficient for the insects to scatter, feed, and accommodate themselves to the new environment—the clothing and body were treated with preparations.

A large number of experiments with various insecticides was performed. The results, however, of both sets of experiments were unsatisfactory from the point of view of obtaining consistent and comparative figures. More experiments, impossible at present, are required. It may be that such exact figures cannot be obtained by the very nature of the experiments. It is quite possible that the preparations act with greatly varying results upon different men. When opportunity is afforded, other experiments will be conducted upon more cases, and for longer periods. Till the incorporation of such results, the figures available at present are withheld.

Insecticides act in two ways: (1) The effect upon the pest present, and (2) the deterrent effect on any of the insects present externally.

The vermicides used when the parasites were present produced either or both of the following effects—they killed or caused to evacuate. Use is made of certain convenient terms, as follows:

Killing efficiency is measured by the percentage of insects killed in a certain time by the insecticide.

General efficiency is measured by the sum of the percentage of insects killed, evacuated, and unaccounted for, in a certain time.

Deterrent efficiency is measured by the percentage of insects which the insecticide deters from reaching the body.

It is possible to give the following notes on certain insecticides.

N.C.I. (naphthalene 96 per cent., creosote 2 per cent., iodoform 2 per cent.).—This preparation is a speedy killing agent, and is the best all-round vermicide tested. The investigator himself prefers it to any other preparation. The following exacting test of its deterrent efficiency was made. Seven hundred lice were allowed to scatter in a sleeping bag improvised from a blanket. The writer used the preparation on the shirt, back and front, and on the riding breeches at the fork and as far down as the knees. The conditions were rendered as favourable as possible for the lice. Socks instead of putties were worn, the shirt neck was opened, and the sleeves rolled up as far as the elbows. Almost immediately after settling in the sleeping-bag lice were felt crawling in great numbers in the socks, on the arms, and a few at the neck—in fact, at those parts of the clothing and body not treated with the powder. Next morning, examination of the clothing and body gave the following results:

155 dead lice were shaken from the socks;
30 dead lice were found below the breeches' knees;
1 dead louse was found at the thigh;
No lice were found on the shirt.

The point of importance is that the powder was a complete deterrent. The duration of the deterrent efficiency of N.C.I. is illustrated in the instance where thirty men of a machine-gun section of infantry were supplied with the powder. The men since using have not been troubled. Most are of the opinion that the effect of one thorough application lasts five days. A few dusted the clothing every few days as a preventive measure.

Caution.—It is most important to remember that a too free use of N.C.I., particularly at the fork, causes severe smarting. For this reason it is recommended that an ointment insecticide be used in this region. However, used with ordinary care, N.C.I. has undoubtedly proved the best insecticide for general use on the clothing, material, and in living places.

Vermijelli.—This ointment is very effective. It is found that the best way to use it is to anoint the body from neck

to knees. Local application seems only to cause the lice to migrate to those parts of the body not treated.

Crude Oil Ointment.—The materials at hand permitted only a somewhat crude preparation: 2 lb. of soft paraffin was melted and 4 oz. of crude tar oil added. The mixture set like an ointment. Used like Vermijelli, it showed a very much higher killing efficiency than that preparation, and a slightly higher general efficiency. As a deterrent it was subjected to the same test mentioned under N.C.I. and gave a result of 97.7 per cent. efficiency.

N.C.I. and Vermijelli.—The ointment was smeared at the fork of the trousers and the seams, the N.C.I. being dusted down the shirt and trousers. The killing efficiency of N.C.I. was increased slightly, but the general efficiency was increased highly.

The report received from the medical officer of one infantry unit which used the preparations in the trenches is convincing. The preparations were efficient from three to seven days. After about the third day it was found that young lice appeared, obviously from eggs on the clothing. Periodic treatment is therefore necessary. There was a great demand for more.

N.C.I. and Crude Ointment.—Used as above, the results were very similar.

Mercury Ointment (variously termed blue unction, blue ointment, and navvies' butter).—To prevent undue absorption of mercury into the skin equal quantities of the ointment and soft paraffin were mixed. The killing and general efficiencies were both high when the ointment was used like Vermijelli. It is feared, however, that the nature of the preparation precludes that consistent use which present conditions demand. To verify its effect as a deterrent, a similar test as in N.C.I., but employing only 300 lice, was carried on in accordance with a well-known treatment. Strands of tape, well smeared with the ointment, were fastened round the ankles, knees, waist, arms, and neck. The precautions proved utterly useless. The lice simply swarmed over the body. After a somewhat unhappy two hours, and to secure rest, the body was smeared all over. Yet next morning 35 live lice were found on the body and clothing.

White Mercury Powder.—This preparation had very low killing and general efficiencies.

Sulphur.—Three experiments, one personal, were performed. In one case, an ointment, half flowers of sulphur and half soft paraffin, and in two cases a generous amount of flowers of sulphur, were used. They proved such complete failures that it is not proposed to pursue further experiments with these substances.

Treatment of Infested Underclothing.

The following notes are the result of many experiments carried on under the everyday working conditions at the divisional baths, treating clothing in quantity in large cauldrons, tubs, and disinfectors.

Thresh Disinfectors.—For the horse-drawn "Thresh" it was found best that not more than one hundred garments should be steamed at 215° F. for three-quarters of an hour. For the Foden lorry "Thresh" one hundred garments per chamber should be steamed at 220° F. and 5 lb. pressure for half an hour.

Boiling Water.—When shirts have been boiled five minutes in water, lice are killed, and the eggs become white and opaque, owing to the coagulation of the protoplasm. As a check, eggs at different parts of the shirts were incubated on the body for fourteen days. None hatched. Since writing the above it has been ascertained that Mr. Bacot, Entomologist to the Lister Institute, working on a small scale with small numbers of eggs and test tubes, found that boiling for one and a half minutes was sufficient to kill the eggs.

Cresol Solution, 1½ per cent. cold.—This solution is bactericidal strength. It was found, after thoroughly soaking infested shirts for one hour, that the lice were killed. Patches holding eggs were rinsed in cold water to get rid of the cresol and the eggs incubated on the body. After thirteen days no eggs hatched.

Chloride of Lime, 7 per cent. cold solution, used for twenty-four hours is effective, but alum, 10 per cent. cold solution, used for forty-eight hours, was a total failure.

Divisional Baths.

Apart from laundry work, the main object of the baths is to turn large numbers of infested men into

clean men as quickly as possible. The three processes are the bathing, the issue of clean underclothing, and the disinfection of the outer garments. The first two are easily carried out, but the last presents many difficulties. Without it the results of bathing and changing are of little value. Treatment by steam or gas disinfection takes too long, as it is usually necessary for men to pass through the baths in a quarter of an hour. Ironing with a hot iron is the most practicable scheme. This is a slow process, but one of cardinal importance, because it determines the rate of bathing. A bathing party being dealt with in a quarter of an hour, the time taken to iron the tunic, trousers, and cardigan jacket of each man being ten or twelve minutes, the number of ironers must equal the number of bathers per quarter of an hour. For example:

Strength of division	19,200
Rate of bathing	1 in 15 days.
Number of men passed through per day	1,280
Number of men passed through per hour (8 hours' bathing per day)	160
Number of men passed through per quarter of an hour	40
Number of ironers required	40

Other considerations that may arise are: This bathing procedure, carried on regularly, will in time reduce the degree of infestation so that the less ironing will be necessary; as local conditions at certain times cause the baths to lie idle, it will be necessary to have other activities to hand, such as laundry or mending work, for the ironers.

RECOMMENDATIONS.

The main object of this section is to suggest an outline for a plan of campaign against the pest.

Research Centre.

The scope of this subject and the virulence of the pest make it necessary that one centre of research be established under a specialist in each army. The apparatus required is really very simple and small in amount. Assistants are necessary for laboratory and outside work.

Advisory work could also be carried on as each unit is frequently a special case. Facilities for transport should also be afforded.

Instructional Work.

At these centres instruction could be pursued by three methods—

1. *Classes*, similar to those carried on for other military affairs, could be initiated for such N.C.O.'s and men (pioneer, sanitary, or R.A.M.C.) as units may specially set apart for dealing with lice.

2. *Lectures and demonstrations* to military units could be arranged, each unit being represented by officers, medical officers, N.C.O.'s, sanitary men, stretcher-bearers, and men in such numbers as may be convenient. A suitable time is when regiments are resting for a period longer than a week. The aims are the presentation of the true facts with regard to the pest, recommendations for dealing with it, and, most important, to foster the idea that it is not by any means impossible to bring the parasite under.

3. *Issue of Leaflet.*—A short leaflet embodying the following could be printed and distributed to all ranks—

Campaign against Lice.

It is not correct to think that lousiness cannot be reduced to a minimum. Experiments, in detail and on a large scale, carried on among soldiers in billets and trenches go to prove (1) that the soldier himself is the main source of infestation, (2) that the measures suggested below are of great benefit.

1. Whenever possible, and as regularly as possible, search the clothing thoroughly for both lice and the "nits" or eggs. If you have discovered that the removal of the white patch which binds the seams at the fork of the trousers does not interfere with comfort, it is well to remove the patch. Special care during searching for the lice and eggs should be paid to this region.

2. The great source of danger is the presence of eggs on the clothing. These hatch in about a week. It is necessary therefore that the trousers should be ironed and brushed at least once a week. While in the trenches it is often quite possible without undressing to use a piece of hot metal or a tinder lighter. This removes the source of danger upon yourself.

3. *Against the lice themselves*, whenever you find it necessary, use the remedies recommended. Powders, as a rule, should not be used at the fork, but down the shirt and trousers. Care should be taken to see that any powder which falls from the shirt to the fork should be small in amount, as too much is

liable to cause smarting. If your stock of ointment and powder is exhausted, apply to the man in your unit who is responsible for the distribution of these preparations.

4. Just previous to going to the trenches be careful to treat the clothing and body as directed.

5. Use the preparations about every four days. Experiments in the trenches have shown this to give the best results.

6. See that any material, blankets, empty sandbags, etc., which may be present to increase the comfort of the dug-out or billet, are treated with the powder preparation.

7. Take advantage of all the facilities offered at the baths.

Divisional Baths.

1. Each division should be provided with two baths, each capable of dealing with eighty bathers per hour, and two Foden lorry Thresh disinfectors.

2. Baths should be built, and not improvised (except in specially favourable circumstances) from permanent buildings. The design of the building should be such that contamination is impossible.

FIG. 10.—Suggestion for a Divisional Bath (from one now working at the front.)

3. *Procedure for Bathing.*—Man strips in undressing room, outer clothing handed in or collected for ironing; then enters bathroom, and bathes; enters dressing-room, and given clean change of underclothing, uses insecticide, receives ironed clothing, and dresses.

4. *Treatment of Underclothing.*—Laundry work may possibly be carried on with advantage at one centre, and not at each bath.

A. *Garments Disinfected in Thresh Apparatus.*—Three-quarters of an hour at 215° F., in horse-drawn type; half an hour at 220° F., and 5 lb. pressure in the Foden lorry type; washed; dried; folded; stored.

B. *Cresol Solution, Auxiliary Method, Suitable for Detached Units.*—Steep garments thoroughly for two hours or more in solution (1 pint of cresol to 8 gallons of cold water); rinse to rid of surplus cresol; wash, etc., in usual way.

C. *Boiling Water, Auxiliary Method, Suitable for Detached Units.*—Allow garments to soak thoroughly and remain in boiling soapy water for five minutes; remove, and wash, etc., in usual way.

5. *Treatment of Outer Clothing.*—Clothing collected (tunics, trousers, and cardigans), ironed with hot iron, particularly at seams and forks of trousers; brushed with a hard brush; distributed to men in dressing-room.

For the Trenches.

While a unit occupies a trench it should be the duty of a man set apart for the work to see that an adequate supply of insecticides is available for distribution to the

men, and for general use in the dug-outs. Company officers should see that their men take the necessary precautions against the pest.

For Billets.

This applies particularly to infantry in the rest areas and to isolated units, such as ammunition columns and infantry transport:

1. Men should be afforded set times for the express purpose of inspecting their clothes.

2. A general inspection by the company officer or medical officer is recommended at least once a week, but men of known unclean habits require special attention, if only for the sake of their comrades.

3. A keen look-out for cases acting as bad lice-carriers should be maintained and such men dealt with speedily.

4. In addition to existing methods for maintaining clean billets, all old clothing should be removed. Floors and skirting boards should be washed with soapy water to which has been added crude oil and cresol.

5. If bathing and changing facilities do not exist, the ironing of garments should still be attempted.

For Hospitals.

These remarks apply particularly to hospitals and rest stations carried on by field ambulances, where conditions are frequently difficult.

Even if patients are retained for one night some measures should be employed. When possible a patient should bathe, have a change of underclothing, and have the outer garments ironed.

None of these recommendations are difficult in themselves. The real difficulties are in the regular and persistent use of the methods during exceptional and trying circumstances. For troops living in billets and hospitals the work is feasible, but for infantrymen matters are more difficult. It is necessary, however, to emphasize that the most effective measures may be carried on while men are out of the trenches. In the trenches the work necessary is reduced to the regular distribution and use of insecticides.

To conclude, the matters of cardinal importance are, first, that a definite plan of campaign be formulated, and secondly, that the plan be followed up vigorously by the work of proficient men. It is not so much a problem of pure science as one of common sense management.

NOTES ON

PEDICULUS HUMANUS (VESTIMENTI) AND PEDICULUS CAPITIS.*

By A. BACOT,

ENTOMOLOGIST TO THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.

BODY LICE, *Pediculus humanus (vestimenti)*, and head lice, *P. capitis*. were reared and kept confined in small entomological glass-bottomed boxes, the lids being removed and fine silk gauze (cliffon) stretched across the open ends in their place. The insects fed readily through the gauze when this was placed against the skin. Boxes containing the lice were carried in waistcoat pockets during the day, and placed beneath a belt against the body during the night. The insects had therefore approximately from six to seven hours daily during which they could feed. In one experiment opportunities of feeding during the day were also afforded them, with the result that egg production was increased. The totals and averages of the eggs laid must be taken only as a comparative guide to fertility; in nature, or under more favourable conditions, the numbers would probably be exceeded. It is probable that the conditions were better suited to the body than to the head louse.

Pediculus humanus is larger, more robust, and less active than *P. capitis*; the females having a relatively

* Abstract of a paper in course of publication in the *Journal of Hygiene*.

greater egg-carrying capacity than those of the head louse. The eggs are slightly larger and the number laid was greater, while the habits associated with egg-laying differ, although by transposing the conditions suitable for other species a considerable degree of uniformity may be produced. It is probable that in nature their egg-laying habits are quite distinct.

Cross pairings between the insects are easily brought about and might, under exceptional circumstances, occur naturally. Hybrid strains resulting from pairings of *P. capitis* males with *P. humanus* females, and vice versa, were maintained without trouble until the F_3 generation, and there seemed no reason why such strains could not be continued indefinitely. Nevertheless, the marked disparity in the sexes of the F_1 generation of some crosses between *P. capitis* male and *P. humanus* female was suggestive of the specific rather than the racial rank of the two insects.

The mortality of females of *P. capitis* crossed with *P. humanus* males points in the same direction, but there was no such obvious disparity in the sexes of the first generation of hybrids from this cross, nor was there any marked disparity in the proportion of the sexes in the following hybrid generations.

In size the hybrid insects are approximately intermediate, but inclining in form, activity and habits towards *P. capitis*. Extreme disparity in the size of some individuals of either sex was noted in some of the broods of the F_3 generation; very large males and small females being observed.

Habits.

The body louse exhibits habits of gregariousness, especially during the moulting phases, and a preference for retiring to a particular spot to oviposit, which leads to the clustering of eggs; both of these habits are shown, though in a less marked degree, by *P. capitis*, and it is possible that they might be partly due to the conditions of captivity, though it seems more probable that the divergence in its habitat is accentuating both tendencies in *P. humanus*.

Pairing with both species took place at any hour, and was very frequently observed when the insects were examined after feeding; males with but little food in the alimentary tract were, however, often seen in coitus. The period during which the insects remained together was on several occasions noted to exceed an hour, but no limit of time was determined.

A male of *P. humanus* fertilized 18 out of 21 females placed with him in succession. Attempts with *P. capitis* were less successful; out of four trials one male fertilized 10 females, and might possibly have equalled the record of *P. humanus* but for the scarcity of virgin females while the experiment was in progress.

Eggs are laid by virgin females of both species on the second or third day following the final ecdysis, and continue to be freely laid so long as feeding continues and the body conditions of temperature prevail, but these unfertilized eggs do not hatch. The longest period for which a female *P. humanus* retained the power to lay fertilized eggs after the removal of the male was twenty days; more usually it would seem to be from sixteen to eighteen days. In the case of *P. capitis* the period was considerably shorter, twelve days being the longest ascertained period, while it was usually about seven to eleven days.

The greatest number of eggs laid by any one female of *P. humanus* was 295—an average of 6.4 per day; the daily average of a number of females being 5.1. Females of *P. capitis* showed a lower fecundity—the highest record being 141, with a daily average of 4 per day; the average of a number of females being 3.7 daily. Those figures would probably be exceeded under natural conditions. An experiment in which some females of *P. humanus* were given an opportunity to feed for two hours by day in addition to seven hours each night, showed unmistakably the extent to which egg production was dependent upon food—the average of these females rising to eight per day. The fertility of the eggs laid was unaffected by the increased feeding. The greatest number of fertilized eggs laid by a female *P. humanus* after the removal of the male was 115; with a female of *P. capitis* the parallel figure was 70.

Length of Life.

The life of the male *P. humanus* which fertilized 18 females was 32 days after reaching maturity, while the longest female life after maturity was 46 days—the average of a number of females being 34 days. With *P. capitis* the figures were: Male life 30 days; female life 38 days—the average of a number of females being 27 days. The lives of the hybrid insects were not noticeably shorter than those of *P. humanus* and the hybrids seemed to breed more freely than *P. capitis*.

Tests made with unfed *P. humanus* showed that the longest lives were at a medium temperature of 60° to 65° F.; many of the insects living from 3 to 4 days, while two lived 5, and one 7 days. At 76° F. all died within 5 days, and at 98° F. all died within 3 days.

Newly-hatched larvae, unless fed, lived less than 24 hours at 98° F., and if kept in a box in the vest pocket they lived but little more than a day, unless fed; none survived a second day.

Adults kept in a box in an outer pocket of a walking coat during March lived five days without food.

Of forty young lice which emerged from the egg on the same day the following record of the moulting periods was made:

First Moul.				Second Moul.			
3 per cent. on the 3rd day				15 per cent. on the 7th day			
42	"	"	4th "	72	"	"	8th "
55	"	"	5th "	13	"	"	9th "
Third Moul.							
5 per cent. on the 10th day			 mature			
3	"	"	11th " "			
55	"	"	12th " "			
32	"	"	13th " "			
5	"	"	14th " "			

Cold.

Active specimens of *P. humanus* survived two days at a temperature of 28° F. to 30° F., but none after exposure to these conditions for a week.

Hatching of Eggs.

Under humid conditions in an incubator kept at 87° F.—

3 per cent. of the 1,300 eggs tested hatched on the 7th day			
56	"	"	8th "
33	"	"	9th "
8	"	"	10th "
0.2	"	"	11th "

A test carried out with eggs taken from a stock box—date of laying uncertain, some having been laid possibly as many as three days previously—showed that none hatched at 60° to 65° F., while at 76° F. there was considerable mortality in the egg stage. The hatching period of those that survived was spread over a longer period than usual. At 98° F. the period of hatching only covered five days, while the mortality was not excessive.

To give some idea of the possible rate of multiplication of *P. humanus*, we may estimate the egg period as twelve days and a further twelve days to the maturity of the females. Allowing an average of eight eggs per day, spread over a fertility period of forty days, we find that during her life a single female may have 4,160 offspring.

AN INVESTIGATION OF THE BEST METHODS OF DESTROYING LICE AND OTHER BODY VERMIN.

By J. PARLANE KINLOCH, M.D.,

LECTURER IN PUBLIC HEALTH, UNIVERSITY OF ABERDEEN.

II.

In a preliminary communication¹ to the BRITISH MEDICAL JOURNAL I described some early experiments in breeding lice, which showed that the humidity of the atmosphere was of importance—a fact which I have since ascertained to have been previously discovered by Mr. Bacot, of the Lister Institute, with regard to the breeding of fleas.²

Up to the present I have been unable to determine the constant conditions that would enable lice to breed and live in the incubator, the lice being removed from the incubator only while feeding on the human body. On one occasion, out of some forty experiments with different samples of lice, it was found possible to keep the lice alive and to hatch out their eggs when they were suspended over water by means of a cotton-wool plug

inserted midway in a glass tube kept at body temperature in the incubator, but failure to repeat this result suggests that perhaps some other factor at present unknown is essential to secure the requisite constant conditions.

It has therefore been necessary for the purpose of insecticidal experiments with lice to take them from verminous clothing and expose them directly to the insecticidal agents. To this end a supply of verminous clothing was obtained about twice weekly from military barracks, and from lodging-houses, and the Poor Law institution.

The variation in resistance of lice as found in nature is very great, and it therefore seemed well in all the insecticidal experiments already reported to pass over experiments where death to the louse resulted, if in a similar experiment with another strain of lice an occasional louse appeared to survive. In some recent experiments undertaken for the purpose of testing earlier results I have not found any of the lice to show unquestionable evidence of life after exposure to boiling water even for five seconds. It would therefore appear that in my earlier series of experiments I had been misled in interpreting certain movements as a sign of life, the more that so competent an authority as Mr. Bacot³ has in a recent contribution on the subject stated that he invariably obtained a lethal result. Mr. Bacot, in his interesting and valuable paper, has described a method for breeding and rearing lice in contact with the human body. He found that lice thus reared never survived thirty seconds' immersion in boiling water, and that a temperature of 55° C. (131° F.) maintained for half an hour killed both active lice and their eggs.

Volatile Oils and Phenol Bodies.

I have made some additional tests with oil of cloves and oil of turpentine. I have also experimented with oil of bergamot. I have found that when immersed in oil of cloves for two minutes and then placed on a piece of blotting paper, the lice move freely over the paper. After similar immersion in oil of bergamot only an occasional louse moves, and the movements are feeble. After immersion for the same time in oil of turpentine all the lice are dead. But how far the movements noted are compatible with the ultimate survival of any of the lice has not been determined.

I have also made further tests with the phenol bodies, and in consonance with my former experiments I have repeatedly found a varying proportion of the lice survive half an hour's immersion in a 5 per cent. emulsion of cyllin in water at ordinary room temperature.

Insecticidal Powders.

During the past year I have received several letters from officers of the R.A.M.C., who have indicated that in endeavouring to keep soldiers free from vermin infection much trouble has been occasioned by the rapidity with which a unit once cleansed has been reinfected. It appears that a lice-free unit is generally infected from barns and trenches previously occupied by lice-infected units. In order, therefore, to secure immunity from lice infection, means are required for keeping the clothes and body constantly obnoxious to lice.

I have investigated several insecticidal powders in the hope that one might be found which, when applied to the clothing, would secure the desired result. I first tested the antiparasitic powder described by Mr. Langford Moore⁴; it has been largely used, and has gained a considerable reputation as an insecticide. It consists of

Ammoniated mercury	1 oz.
Zinc oxide	½ oz.
Magnesium silicate	½ oz.

Mr. Moore believes that the zinc oxide, by its astringent and dehydrating effect, inhibits absorption of the slowly ionized mercurial salt, and thus prevents toxic action. The magnesium silicate (or French chalk) is added to increase the diffusibility of the powder on application. I have repeatedly found that lice in contact with this powder at body temperature and humidity remain alive and apparently unaffected after twelve hours—the period of the experiments—and that if suspended over the powder they remain altogether unaffected. It may be that the powder is obnoxious to lice in an indirect manner or when ionization of the mercurial salt has proceeded

further, but I have failed to secure the suitable experimental conditions.

In a similar manner I have tested several powders of unknown composition sold as insecticidal powders for soldiers, and have failed to observe any marked insecticidal effect.

I have made some experiments with freshly ground Dalmatian insect powder (*Pyrethrum cinerariaefolium*). When used at once in the fresh condition it has a definite insecticidal action, commonly killing all lice immersed in it in a period of two hours. The insecticidal value of the powder becomes gradually diminished when it is exposed to the air; after two days' exposure it failed to kill lice even when left in contact with it for several hours.

Naphthalene.

The powder known as N.C.I. powder is being largely used in the army. I have learnt since my experiments with it were completed that it was originally prepared under the direction of a member of the staff of the Royal Army Medical College, Millbank, but I have ascertained from the college that no experiments have so far been published. This powder is being supplied by the South Metropolitan Gas Company, and the chemist of the company has informed me that the N.C.I. powder consists of

Naphthalene	93 per cent.
Creosote	2 "
Iodoform	2 "

I conducted test tube experiments with the powder in two series. In one lice were immersed in the powder, and all were killed within five minutes; usually two minutes were sufficient. In the second series the lice were separated from the powder by cotton-wool, and were exposed only to the vapour from the powder. Here the extreme length of time required for the killing of the lice was about thirty minutes, but in some of the tests the lice were killed in about fifteen minutes. To ascertain the effect of the powder when applied to the human body, pieces of cloth, such as is employed for underwear, were dusted with it and were used for loosely covering lice applied to a portion of the skin for varying periods of time. It was found that the lice were killed within one hour, but that many died within a quarter of an hour. The powder showed no irritant effect, even after application for a period of eight hours. Three series of experiments were made to test the values of naphthalene, creosote, and iodoform separately as insecticides, with the following result:

1. *Naphthalene*.—Specimens of pure naphthalene and of commercial naphthalene were used, and it was found that while lice in contact with freshly powdered pure naphthalene commonly died in one hour, lice in contact with freshly powdered commercial naphthalene usually died in half an hour. These experiments appear to show that the lethal power of naphthalene for lice is dependent in great part on the presence of hydrocarbons and coal-tar derivatives other than pure naphthalene.

2. *Creosote*.—It was found that immersion in fluid creosote for one minute commonly killed lice, but on a rare occasion a louse could be revived. So far it has not been possible to revive any louse after immersion for two minutes. Lice exposed to the vapour of creosote were usually killed in twenty minutes, and no louse was found to survive at body temperature for more than thirty minutes.

3. *Iodoform*.—It was found repeatedly that lice in contact with iodoform, even when buried in it, remained alive for eight hours, but were usually killed after twelve hours. Over the vapour of iodoform lice lived practically unaffected for several days.

It would appear, then, that of the three constituents of N.C.I. powder, naphthalene and creosote have each a strong and iodoform only a very feeble insecticidal action. But before iodoform could be regarded as a somewhat useless constituent of N.C.I. powder it was necessary to be certain that its presence did not markedly modify the action of the powder. To determine this, two powders were prepared, one being the ordinary N.C.I. powder, the other differing only in that it contained no iodoform. In a series of test tube experiments in which lice were suspended over the powders or placed in contact with them it was found that the lethal period was the same for both powders.

Experiments were now made with these powders on the human body, pieces of clothing being dusted with the powder and used for covering lice previously placed on the forearm. It was found that the N.C.I. powder adhered much better to the clothing than did the powder without

the iodoform, and that while the N.C.I. powder commonly killed the lice in half an hour, the N.C. powder required an hour.

In order to determine whether the superiority of the N.C.I. powder depended mainly on its greater adhesiveness for cloth and not on the presence of iodoform, a powder was prepared that differed from N.C.I. powder only in that insecticidally inert magnesium silicate was substituted for iodoform. A comparison of this powder with the N.C.I. powder showed that for practical purposes the action of the two powders was identical.

In a fairly large series of these experiments I have been left with the impression that the N.C.I. powder is very slightly more effective than the naphthalene, creosote, and magnesium silicate powder, and this was to be expected, since iodoform has a slight insecticidal action, while magnesium silicate has no such action. Both powders contain naphthalene and creosote, and, since the price of iodoform at the present time is 25s. 6d. per pound, and the price of magnesium silicate is 4s. 6d., it would appear that the efficiency of the N.C.I. powder would not suffer in any material degree if magnesium silicate were substituted for iodoform.

A solid substance capable of being powdered and of being applied without harm to the human body must be an essential basis of an insecticidal powder. Of all the solid substances I have examined naphthalene is the most actively insecticidal. It would have been of interest to have investigated the toxic effects on man and lice of the solid perchlorethane on account of the high insecticidal value of the chlorine derivatives of ethane. Perchlorethane is a crystalline body with a camphor-like odour, but, so far, I have been unable to obtain a supply of this substance. Theoretically, it is not essential that the solid basis of the powder should be actively insecticidal, provided that it is possible to incorporate actively insecticidal agents with it. In a series of experiments powders were prepared, with magnesium silicate as a basis, and containing various actively insecticidal liquids, such as trichlorethylene and creosote, and were compared with powders containing similar liquids, but with naphthalene as the basis. In every case the greater efficiency of naphthalene as a basis for the powders was substantiated.

Experiments were made for the purpose of ascertaining whether the creosote in the N.C.I. powder could be advantageously replaced by another insecticide. In my early experiments I had found that the liquid preparations most lethal to lice are certain chlorine derivatives of ethylene and ethane. Recently also I have investigated the insecticidal value of anisol (methyl phenyl ether), which appears to enjoy some reputation for this purpose. In a series of comparative experiments with these insecticides and with creosote I have ascertained that trichlorethylene commonly kills lice by immersion in a few seconds, and invariably kills them within thirty seconds. Immersion experiments with tetrachlorethane, pentachlorethane, anisol, and creosote showed that they usually kill lice in one minute, and that no louse survives immersion for two minutes. It is difficult to place these four substances in order of insecticidal activity, so nearly do they agree and so variable is the resistance of the occasional louse, but the experiments showed that tetrachlorethane was slightly more active than creosote, and there can be no doubt as to trichlorethylene being much more active.

The different insecticides were each separately incorporated with commercial naphthalene in the two proportions of 2 per cent. and of 5 per cent., which was found to be the limit within which naphthalene could conveniently hold the liquids without ceasing to be pulverulent. In a series of experiments with freshly-prepared powders the trichlorethylene powder easily maintained its advantage, commonly killing by contact all lice within a few seconds, while the tetrachlorethane, pentachlorethane, anisol, and creosote powders usually required two to three minutes. But when the powders had been exposed in the open air for some time the results were different. The trichlorethylene powder, when thus exposed for even a few minutes, rapidly deteriorated, and after fifteen minutes' exposure its action on lice corresponded to that of naphthalene alone. On the other hand, the other preparations, initially inferior to the trichlorethylene powder were found, even after exposure to air for a period of one to

three days, to have an insecticidal activity superior to that of naphthalene alone.

Paraffin Bodies.

In experiments with the volatile paraffin bodies, such as petrol and royal daylight oil, it was found that petrol ordinarily killed lice by immersion in one minute and invariably in two minutes, while the ordinary illuminant oils commonly killed in two minutes and invariably in five minutes. When these substances were severally incorporated with naphthalene in 2 and 5 per cent. proportions, as in the other experiments, it was found that even with the freshly prepared petrol powder no insecticidal action greater than that of naphthalene could be definitely determined, and that with the illuminant oil powders the insecticidal action of naphthalene was only slightly increased.

The explanation of these results appears to depend on the rate at which the incorporated liquid is volatilized. The enormous surface provided by the powdered naphthalene must greatly accelerate the evaporation of the added volatile fluid. The rate of evaporation of the several liquids was roughly tested.

Equal weights of each of the liquids were exposed to the air in wide-mouthed bottles of equal calibre for a period of sixteen hours at the body temperature, and the loss of weight noted. Petrol and trichlorethylene were found to evaporate much more rapidly than any of the other substances, and petrol more rapidly than trichlorethylene. Then next in order came tetrachlorethane, royal daylight oil, pentachlorethane, anisol, and, finally, creosote with the lowest vapour pressure of the series.

Creosote would therefore appear, when all conditions are taken into account, to be the most valuable of the actively insecticidal liquids for admixture with naphthalene in an insecticidal powder. When mixed with naphthalene the immediate lethal effect of creosote is less than that of the trichlorethylene powder, but the much longer period during which creosote continues to exert its action more than compensates for this initial disadvantage.

N.C.I. powder has been objected to on account of its moist condition. The chemist of the company supplying the powder has informed me that the use of liquid creosote renders the powder apt to clog in the perforated tins in which it is supplied, and that it has been suggested that the creosote might be replaced by pure phenol. I have not been able to satisfy myself that the substitution of phenol for creosote makes any practical difference to the dryness of the powder, and tests made with the phenol powder on various individuals show that the skin in not a few instances is distinctly irritated by the phenol.

I have made some experiments to determine if the N.C.I. powder could be made drier, and therefore more easily dusted, by some variation in its composition and yet retain its efficiency. In some experiments such efflorescent salts as disodium hydrogen phosphate, sodium sulphate and sodium carbonate were added in turn to the extent of 5 per cent. to N.C.I. powder; when these preparations were kept in sealed bottles the various efflorescent salts exerted no drying effect of practical importance, every preparation tending to cake and adhere to the bottle. In this condition the powders were found to retain their insecticidal activity unimpaired. When, however, the powders in these experiments were exposed to the open air drying occurred in from one to two days, and the powders became very suitable for application through perforated tins. But on testing the insecticidal properties of the dried powders, it was found that their values had greatly deteriorated, and that in a well-dried powder lice could live for hours apparently unaffected. It would appear that the coal-tar products on which the insecticidal effect mainly depends are volatilized. So far it seems impossible to dry a naphthalene-creosote powder and at the same time retain the efficient moist and volatile hydrocarbons and other coal-tar derivatives.

In perforated tins any naphthalene-creosote powder must gradually lose its insecticidal properties, and the moist nature of the powder precludes its being used successfully in these tins. It would therefore appear to be desirable that naphthalene-creosote powders, such as N.C.I. powder and naphthalene, creosote and magnesium silicate powder should be supplied in sealed tins of small size. I believe that the application of such powders twice weekly

to clothing would destroy any lice that might be present, and would practically keep the persons lice-free.

Gases.

Experiments have been made in which verminous clothing was exposed to chlorine, formaldehyde, and sulphur dioxide. In one series articles of clothing infested with lice were placed for one hour in air heavily charged with each of the gases. It was found that chlorine had least effect. Some of the lice on the surface of the clothing were killed, many of them were stupefied, but many remained active. Formaldehyde stupefied all the lice on the surface of the clothing, but many afterwards revived; lice protected by folds of clothing remained active. Sulphur dioxide killed all lice on the surface of the clothing, but only stupefied lice protected from the gas by folds of clothing. Many of such lice afterwards revived. In some experiments where articles of clothing infested with lice were placed in rooms and exposed for twelve hours to these gases as ordinarily employed for disinfecting purposes a somewhat similar result was obtained.

A few experiments similar to those described by Blacklock⁵ when investigating the resistance of the bed-bug to gases were made to determine directly the insecticidal action of sulphur dioxide. When lice were placed in a two-way glass tube through which sulphur dioxide was passed from a pressure bottle, they were killed in a few seconds, and no louse survived five seconds. In another experiment the gas was poured into a deep vessel and the lice dropped into it. Here also the lice were all dead within five seconds. Lice wrapped in cotton-wool and dropped into the jar were all dead after one minute, but when wrapped in pieces of clothing and dropped into the gas an occasional louse was found living after one minute, but none survived after two minutes.

Sulphur dioxide has, therefore, in these experiments maintained its reputation as the most efficient gaseous insecticide, but as ordinarily used for disinfecting purposes it cannot, owing to lack of power of penetration, be depended on to kill all lice in verminous clothing.

Emergency Cleansing of Clothing by means of Petrol.

In a letter to the BRITISH MEDICAL JOURNAL of June 26th, 1915, Dr. Davison, Monkseaton, Northumberland, indicated that in some cases it would be of value to medical officers responsible for the cleansing of soldiers if a safe and economical method for cleansing an occasional verminous kit by means of petrol might be devised without having recourse to the installation of an elaborate dry cleaning apparatus. It is obvious that any such method to be practical must be free from the general danger of fire and from possible damage to clothing as a result of excessive heat. It was necessary, then, to devise a method of vaporizing petrol without danger from fire so that it could be applied in emergency on active-service or for the occasional verminous kit at home. In experimenting with various substances, such as boiling water and red-hot iron, as sources of heat, I found that a stone heated in the fire to a dull red heat and then transferred directly into a basin of petrol is the best means of securing the evaporation of petrol with safety. I arranged a box roughly divided into a lower and upper compartment by means of a wire screen. The verminous garments were placed in the upper compartment and the box closed. A door at the side gave access to the lower compartment, containing a basin of petrol into which a hot stone was introduced. The evaporation of the petrol proceeded rapidly, but it was found that the petrol immediately condensed on the nearest cold surfaces. Thus the lower layer of clothing was moistened with petrol, and the lice there were killed, but no penetration occurred and many lice survived. To secure the insecticidal action of the vapour of petrol a regulated oven would have to be employed, and this is costly and not available for emergency purposes.

It would appear, then, that for the purposes indicated immersion of verminous clothing in petrol remains the most suitable method. Danger from fire would be diminished by using a petrol soak tank with a well-fitting lid, but the danger in wringing and removing the garments would remain. Such a tank could be placed in an open shed, apart from any building, and the petrol-treated clothing exposed to the outside air would dry within an

hour. Similarly, an enclosed rotary hand washing machine, costing about £4 4s., might be employed for the purpose, and this would also permit of the clothing being dry-cleaned.

Recently a further problem in the control of lice has arisen in towns where rest houses have been provided for soldiers delayed by train connexions or otherwise while travelling home on leave from France. In many cases the soldier remains in the town for too short a time to permit of efficient cleansing of himself and his kit, and until it is found convenient to cleanse all soldiers granted leave the use of an actively insecticidal powder in these houses is the best method.

Cleansing of Verminous Heads.

The superior value of the chlorine derivatives of ethylene and ethane as destroyers of lice, and their non-inflammable properties, as previously recorded, led me to suggest that these bodies might be employed with advantage in the cleansing of verminous heads, and I suggested that they might be employed as soap preparations and in vaseline pomades. Recent experience in hospital has indicated that nurses were averse to shampooing verminous heads, and has led to tests being made with these chlorine derivatives undiluted. The effect of trichlorethylene when applied freely to the scalp is variable. Little discomfort seems to be produced in some cases, but severe—though transient—pain results in others. In similar tests it was found that tetrachlorethane is usually free from severe irritant action. One consideration was the danger that these bodies when applied to the hair might accidentally reach and injure the eyes. It has been found in practice in hospital that the desired result is obtained when the hair is gone over carefully with pieces of cotton-wool moistened with either trichlorethylene or tetrachlorethane, and irritant effects to the scalp and eyes are obviated. In the great majority of cases one application has been sufficient to destroy all lice and nits, and rarely have more than two applications been required. Tetrachlorethane, although less powerful than trichlorethylene, is very actively insecticidal, and may be preferred to trichlorethylene on account of its less irritant properties, and this is of importance in dealing with verminous heads on which skin is broken.

Conclusions.

1. As Mr. Bacot has shown, and as my later experiments also demonstrate, lice do not survive immersion in boiling water.
2. Several insecticidal powders have been tested, and of these N.C.I. powder is the most destructive to lice.
3. Of the three constituents of N.C.I. powder, naphthalene and creosote have each a strong insecticidal action. The insecticidal action of iodoform is feeble.
4. Naphthalene appears, so far as my comparative tests have gone, to be the most suitable basis for use in the preparation of a powder destructive to lice. Commercial naphthalene is more actively insecticidal than pure naphthalene, and it appears that the lethal power of naphthalene for lice is dependent in great part on the presence of hydrocarbons and coal-tar derivatives other than pure naphthalene.
5. The immediate lethal effect of creosote when mixed with naphthalene is less than that of some other insecticidal liquids, but the longer period during which creosote continues to act more than compensates for the initial disadvantage.
6. In addition to its feeble insecticidal activity, iodoform greatly increases the adhesiveness of N.C.I. powder for cloth. The inclusion of iodoform in the powder is accordingly justified, although similar adhesiveness of the powder is obtainable at less cost by substituting the insecticidally inert but cheaper magnesium silicate for iodoform in the powder.
7. The insecticidal power of naphthalene-creosote powders gradually diminishes when they are exposed in the open air.
8. The moist nature of such powders precludes their being used successfully in perforated tins, and it has not been possible to dry the powders and at the same time retain the moist and volatile hydrocarbons and other coal-tar derivatives on which the insecticidal effect mainly depends.

9. It is desirable that naphthalene-cresote powders should be supplied in sealed tins of a uniformly small size, or of sizes suitable for the immediate requirements of a convenient number of persons proposed to be treated at one time.

10. In experiments with gases, sulphur dioxide has maintained its reputation as the most efficient gaseous insecticide, and all lice exposed to an atmosphere of the gas die within five seconds. As ordinarily used for disinfecting purposes and as a result of lack of penetration sulphur dioxide cannot be depended on to kill all lice in verminous clothing.

11. For the emergency cleansing of clothing by means of petrol, immersion of the verminous clothing in petrol remains the most suitable method. To secure the insecticidal action of the vapour of petrol a regulated oven would have to be employed.

12. The superior value of certain chlorine derivatives of ethylene and ethane as insecticides and their non-inflammable properties indicate their use in the cleansing of verminous heads. The desired result is obtained and irritant effect on the scalp is obviated when the hair is gone over carefully with pieces of cotton-wool moistened with either trichlorethylene or tetrachlorethane. Tetrachlorethane, although less powerful than trichlorethylene, is very actively insecticidal, and is to be preferred to trichlorethylene on account of its less irritant properties.

MEMORANDUM ON

THE TREATMENT OF INFECTED WOUNDS
BY PHYSIOLOGICAL METHODS.

(*Drainage of Infected Tissues by Hypertonic Salt Solution, and Utilization of the Antibacterial Powers of the Blood Fluids and White Blood Corpuscles.*)

BY

COL. SIR ALMROTH E. WRIGHT, M.D., C.B., F.R.S.

1. INTRODUCTORY.

THE treatment of septic war wounds divides itself naturally into three therapeutic procedures:

(1) In the first we have a number of different aims to pursue concurrently, and have therefore to be ceaselessly on the watch. We have to promote the destruction of the microbes which have been carried into the deeper tissues. We have to re-establish normal conditions in those tissues, resolving the infiltration in the walls of the wound and getting rid of the infected sloughs, and we have to prevent "the corruption of the discharges," and inhibit microbic growth in the cavity of the wound.

Further, during the whole period occupied by these operations we have to be constantly on our guard to prevent active and passive movements which would propel bacteria along the lymphatics, and carry poisonous bacterial products into the blood.

(2) When the microbes in the deeper tissues have been exterminated and physiological conditions have been restored, and the wound has been rendered to naked eye inspection perfectly clean, the difficult portion of our task has been accomplished, and the time has come for dealing with the surface infection.

(3) As soon as this has been suppressed, or all but suppressed, all our thought ought to be given to promoting the processes of repair, bringing together the tissues, and covering over the denuded surfaces.

2. INADEQUACY OF THE TRADITIONAL METHOD OF TREATING WOUNDS BY ANTISEPTIC APPLICATIONS, INCISION, AND MECHANICAL DRAINAGE.

Inefficacy of Antiseptic Applications.—The ordinary antiseptic combines with every kind of albumin. It thereby loses its bactericidal and its penetrative power. Its bactericidal power is, of course, not finally abolished until the antiseptic has encountered and combined with its full complement of albumin. Its penetrative power—and penetrative power means capacity for diffusing outwards

through any medium in a chemically active condition—is, in the fluids of the wound, very rapidly abolished. For, when the medium which is to be penetrated contains even a trace of albumin, this will immediately quench the "antiseptic emanation"—meaning by this that fractional quantum of antiseptic which is carried out by diffusion into the surrounding fluids.

These general truths are firmly based upon experiment. It can be demonstrated that none of our ordinary antiseptics extirpate microbes enveloped in dead or living tissues, or in serous or purulent discharges; and that none diffuse into the walls or recesses of the wound. The sterilizing action of antiseptics applied in the wound will thus be strictly limited to the destruction of any microbes which may be lying bare; and sterilization will not extend beyond that portion of the wound surface to which the antiseptic is actually applied.

Inadequacy of Drainage as Usually Practised.—The theoretical requirements for a complete scheme of drainage are, first, that there shall be an outflow from the infected tissues to the external surface, or to the surface of a wound cavity; and, secondly, where a wound cavity exists, that there shall be drainage from that cavity to the exterior.

Drainage from the Tissues.—In the customary treatment of wounds, drainage from the tissues is not specially insisted upon—mere incision with or without fomentation being assumed to do in this respect what is necessary. In reality, however, in oedema only will sufficient drainage be given by this method. In tissues of normal density nothing like adequate effusion will be obtained, the lymph flow being here rapidly arrested by clotting and desiccation. And, where we are dealing with densely infiltrated tissues, incisions may fail to furnish even as much as a drop of exudation.

Drainage from the Cavity of the Wound.—Drainage tubes, of course, do not induce any outflow of lymph from the tissues. They drain only from the cavity of the wound—outflow ceasing as soon as ever the well head in the tissues dries up.

Summary of Criticisms on the Traditional Method of Treating Wounds.—It has appeared above (a) that antiseptics do not exert any effective action in the wound either in the direction of extinguishing the infection or keeping down bacterial growth; (b) that the usual procedure of incising and inserting drainage tubes provides, in place of that continuous weeing out from the lymph spaces to the exterior which we require, a drainage which rapidly stanches at the source; and (c) that in the ordinary treatment of wounds no steps are taken to disperse infiltration; or accelerate the separation of the sloughs; or bring antibacterial lymph or phagocytes to the seat of infection.

In short, the treatment of wounds by a combination of antiseptics, incision, and mechanical drainage, is a therapeutic method which constantly disappoints, because it fails to kill the infecting microbes and at the same time fails to give to the organism opportunity for ridding itself of the infection.

And lastly—and this point cannot be too much insisted upon—in the ordinary treatment of septic wounds not nearly enough care is taken to prevent those active and passive movements which lead to the mechanical impulsion of microbes along the lymphatics, and to auto-inoculations.

3. THE IDEAL OF PHYSIOLOGICAL TREATMENT IS TO GIVE INTELLIGENT AID TO THE ORGANISM IN COMBATING THE BACTERIAL INFECTION.

Saline dressings supply a means for evoking, in the infected wound, certain requisite physiological reactions: By their aid we can, while at the same time inhibiting bacterial growth, drain the tissues, resolve infiltration, and promote the separation of the sloughs—besides giving other assistance.

4. PHYSICAL AND PHYSIOLOGICAL ACTION OF CONCENTRATED SALT SOLUTIONS.

(1) A concentrated salt solution will attract water; and, except in the case where a membrane which is impermeable to albumin is interposed, the outflowing current of water will carry out with it the whole of the protein substances which it holds in solution. This means that

hypertonic salt solution applied to tissues lying bare in the wound (or to granulating surfaces) will operate as a *lymphagogue* drawing out from the infected tissues lymph which has spent all its antibacterial energy, and drawing into the tissues from the blood stream lymph inimical to microbial growth.

(2) Brought into direct application upon leucocytes a hypertonic solution (what is in view here is a solution containing 5 per cent. salt) will disintegrate leucocytes, setting free the tryptic ferment they contain.

Such a hypertonic salt solution will also exert a number of inhibitory actions.

(3) It will inhibit the action of the tryptic ferment set free in the wounds.

(4) It will inhibit coagulation and so prevent the sealing up of the orifices through which lymph pours into the wound.

(5) It will inhibit leucocytic emigration into and prevent phagocytosis in the cavity of the wound.

(6) It will inhibit microbial growth.

5. PHYSICAL AND PHYSIOLOGICAL EFFECTS OF NORMAL (0.85 PER CENT.) SODIUM CHLORIDE SOLUTION.

Normal solutions of sodium chloride exercise—as many other substances also do—a positive chemiotactic effect on white corpuscles. In other words, they will when applied to the surface of the wound bring leucocytes to the surface.

In moderately dilute solutions (solutions of 0.85 per cent. are here in view) salt does not interfere with the activity of trypsin, nor does it inhibit blood or lymph coagulation, phagocytosis, or microbial growth.

6. THERAPEUTIC EMPLOYMENT OF HYPERTONIC SALINE SOLUTION IN THE EARLY STAGES OF THE INFECTED WOUND.

By the time the patient reaches the *Casualty Clearing Station* his wound will generally have assumed the characters of a lymph bound, infiltrated, and sloughing wound; or it will be fast getting into this condition. And even though under care in hospital the wound may have been coming out from this condition, it will, on long journeys, when redressing is difficult, be very prone to fall back into it. (*Vide infra*, Subsect. 14.)

The first requirement when we have an infected, lymph-bound, infiltrated, and sloughing wound will be—to get rid of the coating of scab and fibrin adhering to the surface of the wound, and set the lymph-flow going, to resolve the infiltration, and to promote the separation of the sloughs.

This involves two successive operations. In the *first*, we make use of the hypertonic solution undiluted; in the *second*, we turn its dilution to profit.

Stage in which the Hypertonic Solution comes into Operation Undiluted.

The striking feature here will be the outpouring of lymph. But there will at the same time: (a) in the depth of the tissues, (b) on the surface, and (c) in the cavity of the wound, be evoked other reactions which cannot be directly followed by the eye.

(a) *In the depth of the tissues* there will be substituted for the spent lymph which has been extracted lymph freshly drawn from the blood stream. This means that there will be substituted for a lymph which is favourable to the growth of all microbes indiscriminately a lymph which will stop the growth of *saprophytic bacteria* and *imperfect aerophytes* (such as the gas-gangrene bacillus); and at the same time seriously impede the growth of *serophytic bacteria*, above all the growth of the streptococcus.

Further, the microbes in the tissues, which when immersed in the spent lymph were insusceptible, will, immersed in the fresh lymph, become susceptible to phagocytosis.

And in the induction of the phagocytosis in the interior of the tissues, the imbibed salt will, we may take it, play a contributory rôle. For we have seen that salt, appropriately diluted, stimulates leucocytic emigration.

* The inhibition of microbial growth obtained with the serum of the patient with a large or even moderate-sized wound is much greater than that obtained with a normal serum. This, as comparative experiments have shown, is connected with the fact that the antitryptic power of the wounded man mounts up with very steep ascent (that is, in the course of a couple of days), to a level 3 to 8 times higher than the normal.

(b) *In the more superficial regions of the walls of the wound and adhering sloughs*, the hypertonic salt solution will break down the leucocytes and set free tryptic ferment—ferment which will, as we saw, not come into action so long as the concentration of the salt is maintained.

The coagulation of the lymph on the face of the wound will also, as we saw, be inhibited by the hypertonic salt solution.

(c) *In the cavity of the wound*, microbial growth will at the outset be completely arrested by the hypertonic salt, and it will, after the lymph has begun to pour out, be inhibited to different degrees according to circumstances by the combination of salt and antitryptic exudation.

So long as the salt solution is maintained at full strength, both emigration into and phagocytosis in the cavity of the wound will be inhibited.

Sum Total of Clinical Effects Produced by the Undiluted Hypertonic Salt Solution.—There will have been established, in the depth of the tissues, conditions favourable to the extermination of the microbial infection; and in the cavity of the wound conditions which will restrain microbial growth.

Stage in which the Dilution of the Hypertonic Salt Solution is turned to Profit.

As soon as the hypertonic solution in the cavity of the wound has been sufficiently diluted by outflowing lymph, the salt diffuses out from the infiltrated walls of the wound and the sloughs; and with this the tryptic ferment previously set free in these comes into action, and goes about its work of *cleansing digestion*—resolving the products of inflammation in the infiltrated tissues, and severing the connecting strands by which the sloughs are bound to the face of the wound.

At the same time—and this, be it noted, serves as a signal to the eye that the dilution of the salt solution has reached the point where all its inhibitory effects are abolished—leucocytes emigrate into the wound, and the discharge begins to assume a purulent character.

Now, also, the bacteria begin to multiply in the cavity of the wound.

We cannot afford to let all this go on very long unchecked. For as more and more trypsin finds its way into the exudate, or is set free in it from leucocytes disintegrated by microbial poisons, the effusion comes to furnish a more and more congenial nutrient medium for microbes, and the check imposed by phagocytosis is more and more completely removed. Finally, the exudate becomes tryptic, and if the redressing of the wound is any longer delayed, ground will now be rapidly lost (*vide infra*, Subsect. 12—*Indications which call for the redressing of the wound*).

It will have to be remembered, in connexion with this description, that the conditions will in every wound be perpetually changing, and that these changes will not keep time in the different parts of a large wound.

7. UNDER CERTAIN SPECIAL CIRCUMSTANCES THE HYPERTONIC SALT SOLUTION SHOULD BE USED IN A DIFFERENT WAY.

Method in which Hypertonic Salt Solution should be used when Gas Gangrene, Streptococcal Cellulitis, or other Acute Tissue Infection supervenes, or where we are dealing with an Infection of a Joint.—Our whole concern here must be to draw out as rapidly and exhaustively as possible the corrupted lymph which occupies the tissue spaces, replacing this with uncorrupted lymph drawn from the capillaries. To achieve this we must, after freely incising the tissues, or opening the infected joint, apply hypertonic salt solution and maintain this in full strength until we have got the upper hand of the infection.

+ The presence of trypsin in the wound can be very easily demonstrated. We need only collect a sample of pus or slough on a small swab of cotton wool; introduce this into milk containing 2 per cent. of calcium chloride crystal, and then place this at a temperature of 50° to 55° C. (that is, in water just not too hot to hold one's hand in). If trypsin is present the milk will now rapidly clot. But it must be borne in mind in connexion with clotting obtained with a slough that since, under the conditions of the experiment, we dilute our material, our test will give a positive result even when we have in the wound sufficient salt to prevent the ferment being actually operative.

+ This lymph has ordinarily lost some, and in very severe infections it may have lost all, its antitryptic power. Further, in gas gangrene—and let me here interpolate that we have in gas gangrene, when fully developed, a profound acid intoxication—the lymph in the focus of infection often shows a much diminished alkalinity.

Method in which the Hypertonic Salt Solution should be used where we are threatened with Secondary Haemorrhage.—Our aim and object here must be to prevent any digestive action in the neighbourhood of the endangered artery. Translated into practice this means that we must apply hypertonic salt solution and maintain it at full strength so as to prevent any trypsin which may be liberated in the wound coming into action.

8. GENERAL INSTRUCTIONS FOR THE CARRYING OUT OF THE LINES OF TREATMENT INDICATED ABOVE.

Concentration in which the Hypertonic Salt Solution ought to be brought into Application.—For all ordinary purposes the best hypertonic solution to employ is a 5 per cent. solution of common salt. Where we require more vigorous lymphagogic effect we may resort to a 10 per cent. solution, or even to a stronger solution. But these are very painful when applied to skin edges and sensitive granulations; and salt applied in saturated or nearly saturated solutions will often cause sloughing of the superficial tissues (*vide Subsect. 10, Footnote*).

Most Convenient Form of Stock Solution to keep on Hand.—The most convenient stock solution to keep on hand is a saturated saline solution, made by shaking up water with an excess of salt and then allowing this to settle. Such a solution contains at ordinary temperature 35 per cent. of salt.

Diluted 1 part of the saturated solution with 6 parts of water it gives a 5 per cent. solution.

Diluted 2 parts of the saturated solution with 5 parts of water it gives a 10 per cent. solution.

Diluted 1 part of the saturated solution with 39 parts of water it gives a 0.85 per cent. (physiological solution).

N.B.—Hot water should be employed for making the dilutions required for saline dressings and irrigations. For the physiological reactions which are to be evoked, whether these be active hyperaemia and transudation, or tryptic digestion, or emigration and phagocytosis, are all impeded by cold and favoured by heat.

9. METHOD OF APPLYING HYPERTONIC SALT SOLUTION SO THAT IT MAY PRODUCE AN ADEQUATE LYMPHAGOGIC ACTION, AND AFTERWARDS PROVIDE OPPORTUNITY FOR DIGESTIVE CLEANSING OF THE WOUND.

This will be the proper way of employing hypertonic salt solution in the infiltrated and sloughing wound. The following are the points to be borne in mind:

(a) For the achievement of an adequate lymphagogic effect, we must use quite considerable quantities of hypertonic solution. The dressings ought to come directly out of the hot solution, and be applied dripping wet.

(b) In order that there may follow upon the lymphagogic action a cleansing digestion, the amount of salt employed must be kept within such limits as will allow of its being within a reasonable period diluted by the outflowing lymph. In other words, we must not use too much hypertonic salt solution, nor use too concentrated a solution; nor supplement with large packs of saturated salt solution or salt tabloids.*

In order to anticipate that pullulation of microbes which will supervene when the exudate becomes tryptic we ought to redress the wound as soon as the discharge begins to be purulent.

The procedure in carrying out these principles will, of course, vary according to the anatomical conditions of the wound. In point of fact, three different anatomical types of wound have to be considered:

(a) The wound which from the beginning lay fully open, or which has been opened up so as to render every portion of its surface fully accessible;

(b) The wound where, owing to folds, or blind passages, or a tunnelled way, portions of the surface are not fully accessible; and

(c) Tubular wounds which are throughout their whole course more or less difficult of access.

(a) In the first case we have only to pack the wound with gauze thoroughly wetted in hot 5 per cent. salt solution. We cover this in with any impermeable tissue, such as jaconet. When the time comes for redressing the wound all trace of pus ought, before reapplying the saline,

to be carefully removed. For pus treated with strong salt is converted into a sticky intractable substance which forms an impermeable coating on the walls of the wound.

(b) Where the wound is pocketed or tends to flap together the best procedure is to employ a bath of warm 5 per cent. saline. Should the position of the wound render immersion in a bath impracticable, it ought to be irrigated with warm 5 per cent. saline solution, the fluid being distributed over the whole surface of the wound by an arrangement of bandages.[†] The bath or irrigation ought to be discontinuous—intervals for digestive cleansing alternating with periods of lymphagogic and leucocytolytic action.

(c) Where we have a tubular wound it will, of course, be futile merely to insert a drainage tube, and cover its mouth with a piece of gauze wrung out of hypertonic salt solution. The rational procedure will here be to make windows in the tube, to cut it open longitudinally, and to lay into the hollow a folded strip of gauze, thoroughly wet with saturated salt solution. The tube thus arranged is to be introduced into the wound after this has been syringed with 5 per cent. saline.†

10. METHOD OF APPLYING HYPERTONIC SALT SOLUTION WHERE WE WANT TO MAINTAIN ITS STRENGTH UNDIMINISHED, SO AS TO OBTAIN ITS FULL LYMPHAGOGIC EFFECT AND SUPPRESS ALL DIGESTIVE ACTION.

It will be remembered that this is the way in which hypertonic salt solution should be used where we are threatened with secondary haemorrhage, or are dealing with an infected joint, or with gas gangrene infection, or streptococcal cellulitis (*vide supra, Subsect. 7*). Let us consider how, using the ordinary hypertonic solution and the stock of solution of saturated salt, to effect our object in the three types of wound already referred to—the completely accessible, the incompletely accessible, and the tunnel wound.

(1) In the first variety of wound we, as before, pack with gauze thoroughly wet with 5 per cent. salt, but now reinforce by a backing of gauze thoroughly wet with saturated salt solution, and, as before, cover with some impermeable material. Or, as an alternative, we at short intervals renew the hypertonic solution, feeding this in with a syringe through a drainage tube going down to the face of the wound.†

(2) In the case of the only partially accessible wound we resort as before to a bath of 5 per cent. saline or to irrigation with this solution, varying our procedure only in the respect that we make the bathing or irrigation continuous, or as nearly as possible continuous. When immersion in a bath and irrigation are both impracticable the wound ought to be dressed as in (1).

(3) In the case of the tunnel wound, we at short intervals renew the supply of salt; first withdrawing the old wick; then syringing out with 5 per cent. of salt; and then substituting for the old wick a new one taken fresh from saturated salt.

† This procedure might at first sight seem open to objection, (a) on the ground that saturated salt solution would here be brought into application upon the tissues; and (b) on the ground that to obstruct a drainage tube by gauze would be to render it useless. In connexion with the former objection, it will suffice to point out that direct contact of the saturated salt solution with the tissues is avoided by the interposition of the wall of the tube; and that the salt in the wick will come into operation only through the medium of the weaker salt solution with which the wound has been syringed out. In connexion with the latter objection, consider again what we have said in ordinary drainage *ex vacuo*; that is, it is only when we aim at keeping our wound cavity empty, and when we are dealing with a solid pus, and when unaided gravitation supplies in our scheme drainage our whole motive force, that it becomes incumbent to provide an unobstructed conduit to the exterior. In drainage *ex pleno* such as is here proposed we deal with a watery lymph effusion which wells over from the wound; and which only hermetical sealing could balk back.

Another method which has been extensively practised is that of packing the wound with tabloids of salt, holding these off from actual contact with the tissues by several folds of gauze. This would seem to give in different cases different results. In certain cases such as when an open knee-joint is packed with tabloids of salt, disposed throughout the gauze with close and regular inter-spacing—the interior of the wound remains perfectly dry. The explanation would seem to be that the salt here comes into application in the form of a saturated solution all over the surface of the wound, condensing the tissues until they become impermeable to lymph; and at the same time pickling them in such a way as, perhaps, to restrain all microbial growth in their interior. In other cases—for example, where a bagful of tabloids is introduced into the well of a large wound—there is obtained the ordinary lymphagogic effect. Here it would seem that the salt operates in form of a saturated solution upon the portion of the wound only lying nearest to the tabloids. And hereabouts the tissues look and feel exactly like pickled meat. In regions more remote from the tabloids the salt will naturally be much less concentrated. And it is presumably from these regions that the copious lymph outflow is derived.

* In this connexion it will be well to emphasize that to fill into the wound cavity large numbers of salt tabloids must be pronounced wrong practice in the case where we judge the wound to be one which stands in need of digestive cleansing.

11. NATURE OF THE EXTERNAL COVERING TO GO OVER THE WET SALT DRESSINGS.

The most usual practice is to place immediately outside the saline dressings a thick packing of dry cotton-wool, and again outside this a bandage. This seems to be dictated by the idea that the cotton-wool will soak up the discharges, and the notion that the capillarity of the cotton-wool, and evaporation from its outer surface will reinforce the drawing action of the salt. In point of fact, however, all the cotton-wool does is to suck out some of the salt solution from the dressings, and to evaporate this to dryness, putting in this way a certain quantum of salt out of action. Moreover, the notion that capillary action and evaporation would promote drainage from the tissues is in conflict with everyday experience, which shows that when we apply a dry dressing or let a wet dressing evaporate, the outflow of lymph from the wound ceases, and the dressing sticks to its surface.

The rational method of covering in saline dressings is to use, instead of cotton-wool, an impermeable covering.* Then, instead of the salt solution being carried outwards by capillarity and evaporation, it will, by diffusion, be carried in-ward.

The difficulty that with this form of dressing discharges will escape from under the impermeable covering can be met either by frequent redressing or by placing cotton-wool outside the jaconet.

In the case of wounds of the extremities perhaps the simplest method of all is to dispense with all coverings over the salt dressings, merely renewing the salt packs at frequent intervals. But here, if we want to clean off sloughs or resolve infiltration, we shall have to alternate with our dressings of hypertonic saline solution dressings of physiological saline solution.

12. INDICATIONS WHICH CALL FOR THE REDRESSING OF THE WOUND.

A septic wound requires to be redressed under two quite different conditions.

(a) It requires redressing as soon as tryptic ferment is set free in the cavity of the wound, such trypsin being set free from leucocytes broken down by microbic growth.

For here, as soon as the originally antitryptic exudation becomes tryptic, all manner of sero saprophytic microbes will multiply unrestricted; and bacterial poisons may be absorbed; and, at the same time, phagocytosis will be inhibited; while the young tissue elements, which are the agents of repair, will be subjected to destructive digestion.

(b) Again, every septic wound ought to be redressed as soon as it becomes lymph-bound.

For as soon as the exudation stanches and lymph fresh from the blood ceases to come into application, the microbes in the tissues, being now no longer inhibited by their growth or phagocytosed, find congenial conditions and multiply.

It requires to be emphasized in connexion with these two indications for redressing that in the case of the septic wound intervention is much less urgently called for, where we have retention of corrupted discharges, than where the wound becomes lymph-bound.

In the case of the former all we have to fear is a pullulation of microbes in the cavity of the wound, some absorption of septic products, and some injury of the tissues of repair.

In connexion with a lymph-bound wound we may at any moment have a wide extension of the tissue infection, taking the form of gas-gangrene or streptococcic cellulitis.

13. PRINCIPLE UPON WHICH CASES OUGHT TO BE CHOSEN FOR REDRESSING WHERE PREFERENCE MUST BE GIVEN TO THE MORE URGENT.

What has been said above on redressing ought to be specially kept in mind where it is impossible to inspect and redress every wound.

In such cases the surgeon has, as a rule, simply pursued the practice followed in ordinary aseptic operation wounds. That is, he has with a view to preventing the invasion of

microbes from without, redressed the cases where the discharge has soaked through, giving to these preference over those with unsoiled dressings.

In septic wounds—for here the microbes are in the citadel and not outside the walls—we ought to follow an exactly opposite policy. Where the outside dressings are wet with discharge, in other words, when presumably lymph is being actively poured out, we may be confident that the wound is not coming to any harm. We may accordingly, when other work presses, quite properly postpone redressing such cases. The contrary will hold of a gravely wounded man whose dressings are unsoiled. In such a case it is always possible that we may underneath quite clean dressings have a lymph-bound wound. We ought without delay to satisfy ourselves with respect to this.

14. PRECAUTIONS TO BE TAKEN IN HANDLING THE WOUND TO PREVENT AUTOINOCULATIONS AND A DISPERSAL OF SEPTIC INFECTION ALONG THE LYMPHATIC CHANNELS.

Like the acutely sick all the wounded are suffering from a bacterial infection. And the same general therapeutical principles apply. So long as microbes in large numbers are harboured in the tissues we have pyrexia. And the patient's condition will be aggravated by all dispersion of the infection and absorption of bacterial poisons into the blood. So that in every case the infected man will need to be kept at rest; and the really heavily infected will require to be kept at absolute rest.

This requirement is, of course, in the case of those suffering from infected compound fractures more or less perfectly complied with by the application of apparatus for fixing the limb.

But not only wounds complicated by fracture, but all wounds with the infected tissues in their neighbourhood, ought so far as possible to be immobilized. Moreover, this ought to be begun immediately after the wound has been inflicted, and to be continued so long as appreciable infection persists in the depth of the tissues.

In connexion with operative procedures it is, of course, impracticable to conform completely to this requirement. But none the less the requirement should never be lost sight of. It is scientifically reprehensible to cast loose, as is so often done under an anaesthetic, a fractured limb from all splints, deliver it over to an orderly for energetic washing and disinfection, and permit the foot or hand below the fracture to be used as a handle for raising or turning over the limb. All the necessary passive movements ought to be reduced to an absolute minimum. And the light hand of the skilful surgeon will, in operating on an infected case, be a very valuable asset.

In the same way, seeing that very efficient apparatus has now been devised, fractured limbs ought no longer to be put up in such a way as to allow of sagging or displacement during redressing.

Again, in changing the dressings on large flesh wounds on an arm or leg, great care ought to be taken not to manipulate, or flex or extend, or unnecessarily disturb the position of the limb.

It is difficult to doubt that when these precautions are neglected bacteria from the infected area will be propelled along the lymphatic channels in the direction of the heart. And measurements of the opsonic power of the blood and, indeed, simple inspection of the charts, establish that all readjustments of the position of a fractured limb, and probably all redressing of large wounds, are followed by elevations of temperature corresponding to very serious autoinoculations.

The same will, of course, apply to shocks and jolts received when the infected patient is being carried from the ward to the operation theatre, or is being transported by train or motor.

15. MANNER IN WHICH WOUNDS SHOULD BE DRESSED IN PREPARATION FOR LONG JOURNEYS DURING WHICH THEY CANNOT BE KEPT UNDER CLOSE OBSERVATION.

What has been said in the preceding subsections has an important bearing upon the procedure to safeguard the patient against that delay in redressing which is inevitable during the long hours which will be consumed in travelling from the front to the base, or from the base to England, and in settling down into a new hospital. The danger from microbic pullulation in the cavity of the wound and

* The prejudice against the use of impermeable coverings no doubt originates in the observation that discharges, when confined after they have become tryptic, will set to work and digest the surface of the wound. The proper remedy is not to discard the impermeable covering, but either to redress before the discharges become tryptic, or prevent them becoming tryptic.

tryptic digestion, and, on the other hand, the much graver danger of a tissue infection taking origin in a lymph-bound wound, have here to be provided against. This means that we have to arrange for a continuous outflow of lymph, and at the same time to arrange for the surface of the wound being kept thoroughly wet.

The proper course will be to dress the wound as indicated in *Subsects. 10 and 11, supra*, applying outside the impermeable covering dry cotton-wool. Thus treated the patient may arrive at his destination with soaked dressings, but he is not likely to arrive with corrupted pus, and we can be practically certain that he will not arrive with a tissue infection spreading from a lymph-bound wound.

16. METHOD OF CORRECTING CERTAIN UNDESIRABLE AFTER-EFFECTS WHICH MAY SUPERVENE UPON THE ILL-CONSIDERED, OR TOO LONG CONTINUED, USE OF HYPERTONIC SALT SOLUTIONS; AND INDICATIONS AS TO WHEN THE HYPERTONIC SALT SOLUTION OUGHT TO BE DISCARDED IN FAVOUR OF A WEAKER SOLUTION.

The rationale of the therapeutic employment of hypertonic solutions is, as we have seen, to be found in the fact that (1) they drain the tissues; (2) break down the leucocytes in sloughs and in the walls of the wound, and so give us, quite apart from any destruction of leucocytes by microbic agency, the trypsin we require for the digestive cleansing of the wound; (3) they produce active hyperaemia; (4) prevent clotting of the lymph in the walls of the wound; (5) suspend the action of the tryptic ferment set free from the leucocytes; and (6) inhibit bacterial growth—the inhibitory actions last in question being exerted only so long as the strength of the salt solution is maintained. In addition—but this counts of course as a disadvantage and not as a therapeutical asset—hypertonic solutions repel leucocytes and prevent phagocytosis.

If we want, in employing hypertonic salt solution, to turn its therapeutical qualities to best advantage, we must be continually on the watch to anticipate and correct any of the defects of its qualities.

(1) Where blood continues to ooze from an operation stump or wound which has been packed with hypertonic salt solution, this will be due to this anticoagulative agent having been applied before bleeding has stopped. The proper procedure will always be to postpone the use of hypertonic salt until all oozing of blood has ceased. Applied then, the salt will not resolve the blood clot; and where the hypertonic solution applied is a 5 per cent. solution, a very little dilution will bring it to the point when blood clotting will no longer be inhibited.

(2) When the face of the wound is found covered with a firmly adherent glutinous coating, this has been derived from leucocytes broken down by the direct application of strong salt.

The way of avoiding this obstacle—it is, as a matter of fact, a serious obstacle to effective draining and irrigation—is to clean out all pus from the wound before bringing the hypertonic salt solution into application.

(3) Where, as very rarely happens, the granulations become oedematous this will be due to the over-prolonged application of concentrated salt solutions.

It would seem that here the salt which is imbibed into the granulations is not sufficiently promptly carried off by the circulation, with the result that fluid is drawn into the salt-impregnated tissues, both from the underlying strata and also, when their salt content diminishes, from the discharges.

The remedy will be to discontinue the application of salt, and to apply hot fomentations in order to activate the circulation and promote absorption.

(4) Where the granulations assume a bright coral red colour and bleed at the least touch, it will be well to reduce the concentration of the salt solution—in the case where drainage of the tissues is still required to 2.5 per cent., and in the case where no further lymphagocic effect is required to 0.85 per cent.

(5) Quite apart from the development of any undesirable secondary effects, it will be well, as soon as every trace of induration has disappeared and all sloughs have been got rid of, to substitute for the hypertonic a physiological salt solution.

The rationale of this is that there will here still remain on the face of the wound, even though it looks to the

naked eye perfectly clean, serophytic microbes, which, though quite at home in the serum, can be killed by phagocytosis.

In order to kill these—and let us note that they are not killed but only inhibited in their growth by hypertonic salt solution—we must bring leucocytes to the surface of the wound.

17. THERAPEUTIC APPLICATION OF PHYSIOLOGICAL SALT SOLUTION.

What remains to be done is (a) to destroy the serophytic bacteria—streptococci and staphylococci—which still survive upon the face of the wound; and (b) to reduce the extent of surface lying open to infection, holding before ourselves always as an ideal the closure of the wound by secondary suture.

Destruction of the Serophytic Microbes remaining on the Face of the Wound.—A surface infection such as we have still to deal with can be effectively combated by keeping the wound wet with physiological salt solution, and redressing at short intervals. The application of physiological salt solution will, as we have seen, promote the emigration of phagocytes, the frequent redressing will prevent the setback that will occur every time that leucocytes die off and set free their trypsin in the wound; and the combination of the two will, in the case where the deeper tissues have been freed from infection, either exterminate the surface infection, or at any rate so nearly exterminate it as to make it safe to embark upon an operation for the closure of the wound.

18. FINAL STAGES IN THE TREATMENT OF THE WOUND.

Conditions under which Wounds may be Closed by Secondary Suture.—Secondary suture may be safely embarked upon when we have favourable bacteriological conditions in combination with favourable anatomical conditions.

The bacteriological conditions may be pronounced favourable when (a) microscopic examination of fluid from the depth drawn out by a "lymph leech"; or, failing this, clinical evidence points to the probability of our having got rid of all the deep infection, and when (b) stained impression preparations made from the wound surface show that we have there large numbers of perfectly well-conditioned polynuclear leucocytes, and a complete absence of microbes, or only here and there a stray microbe.

The anatomical conditions are favourable when we can, with or without undercutting, bring together the skin edges without putting too great a strain upon the sutures, or leaving underneath any hollow spaces. The operation of secondary suture may be undertaken either before the wound surfaces are covered in with granulations, or subsequent to this—the former of these dates being, from the bacteriological point of view, the more favourable, in the respect that there will be less risk of infection lurking below the surface.

It will, in every case, be advisable—for the conditions may change within the lapse of a few hours—to let the operation follow immediately upon the examination of the impression preparations.

In connexion with secondary suture, as in every other case where a wound is sewn up without adequate guarantee for its asepticity, it will always be imperative to keep the patient under the anxious observation of the operator for at least a week afterwards.

Procedure where the Wound cannot be Closed by Secondary Suture.

When the anatomical conditions do not allow of the wound being closed by secondary suture, we must fall back on the policy of persistently combating the surface infection, consolidating the granulations, and encouraging the covering in of these by epithelium. In the present state of our knowledge perhaps the best we can do will be to employ dressings of physiological salt, or, better, of Ringer's solution (for this contains a large assortment of physiological useful salts); redressing the wound frequently. Where we are dealing with a large defect of skin, grafting may usefully be resorted to.

British Medical Journal.

SATURDAY, JUNE 3RD, 1916.

THE POSITION OF MEDICAL MEN UNDER THE MILITARY SERVICE ACTS.

THE Central Medical War Committee, the Scottish Medical Service Emergency Committee, and, for certain special cases, the Committee of Reference formed by the Royal College of Physicians and the Royal College of Surgeons, are now recognized under the Regulations made under the Military Service Acts as the Professional Committees for all medical men who come within the provisions of those Acts. The effect of this recognition is that every medical man, married or single, under the age of 41 next birthday, and consequently liable for service in the army, will be subject to the decision of one or other of these three committees on the question whether it is his duty to take a commission in the R.A.M.C. or to continue to carry on his work as a civilian practitioner.

At the present time practitioners of military age in England and Wales may be divided into those who have enrolled and those who have not enrolled under the scheme of the Central Medical War Committee, the former being in the majority. A medical man under 41 who has enrolled will not be called up for service with his class by the recruiting authorities. He will continue in his present occupation, but be liable to be called upon to take a commission in the R.A.M.C. if and when the Central Medical War Committee decides that it is his duty to do so. If by inadvertence such an enrolled man receives a notice from the recruiting authorities calling him up, the production of his certificate of enrolment restores him at once to his proper position in accordance with Army Council Instruction 485 as follows:

(a) If a qualified medical practitioner who is attested under the Group System, or is in one of the classes under the Military Service Act, 1916, and who is enrolled under the scheme of the Central Medical War Committee or the Scottish War Emergency Committee, or has been provisionally accepted by the War Office, receives a notice paper calling him up, he should return it to the recruiting officer, together with his certificate of enrolment or War Office letter. The notice will then be cancelled, and the practitioner will remain in reserve until selected for a commission in the Royal Army Medical Corps.

In Scotland the same procedure applies with regard to those who are registered with the Scottish Medical Service Emergency Committee.

There is, however, one important modification in the position of the enrolled man under 41 which has resulted from the passing of the new Military Service Act. Hitherto medical men who have taken service since the beginning of the war, as doctors in the army, have done so on the system of a contract for one year or until their services are no longer required, whichever happens first. It is now announced authoritatively that every medical man under 41 is, in virtue of the new Acts, under an obligation to serve not only for twelve consecutive months, but for further periods of twelve months, with such intervals as may be determined, if the military authorities (acting on the advice of the Professional Committees) require him to do so.

In view of the obligation that now exists on all other classes of the community to serve for the duration of the war, the medical profession will not, it may be assumed, object to this new condition in the case of men under 41. While service with the forces remained voluntary, the Central Medical War Committee was fully aware that a medical man by enrolling undertook no more than an obligation for one year of service, if required of him. At the same time the Committee always contemplated the possibility that circumstances, such as the prolonged duration of the war, might necessitate a further call on men who had completed a year's service. For this reason each medical man, on the completion of his period of service in the R.A.M.C., was invited to renew his enrolment, thus placing himself again at the disposal of the army, should the Committee advise that his services were required at any subsequent date.

Under the new conditions every medical man under 41 who at the end of his period of commissioned service elects to return to civil life will come under the compulsory provisions of the Military Service Acts, and unless he at once enrolls again so as to obtain the privileges afforded by Army Council Instruction 485, he will be liable to be called up for ordinary service by the recruiting officer. He will, no doubt, consider it advisable to enrol, and he will therefore again come before the appropriate Professional Committee for commissioned service in the R.A.M.C. so soon as the Committee thinks it is his turn to be taken again. What interval should be allowed between the end of his first period and the beginning of his second period of service will be determined by the Professional Committee. It may be presumed that the Professional Committee will not select an enrolled doctor for a second period of service while other men equally eligible in other respects have not been taken for service. The enrolled medical officer, therefore, who is completing his year's service may reasonably hope that it will usually be found possible to arrange that the second period of service, if any, which he will be called upon to render will not be directly consecutive to the first period, but that there will be an interval, the exact duration of which it is not possible to state, inasmuch as it will depend upon the national requirements at the time; at the same time any medical officer who prefers that his service in the R.A.M.C. should be continuous may, as heretofore, re-engage at the end of his year.

With regard to the medical men under 41 who enrolled before the passing of the Act, the Central Medical War Committee cannot consider them to be morally bound to give more than one year's service on that enrolment. Among them are some who are now engaged in their first year's service in the R.A.M.C. and others who have not yet held a commission. In addition there are the men who have already done a year's service in the R.A.M.C. and have resigned their commissions. There is no doubt that the man under 41 who at the end of his year's service resigns his commission should enrol again under the new conditions, realizing, of course, that the obligation is now, in virtue of the new Act, not limited to one period of service of twelve months, but extended to such further period or periods as may be found necessary in his case by the War Office, acting on the advice of the Professional Committee. By enrolling he will be helping to retain for the medical profession certain privileges, for doctors will then continue to be able to fulfil their obligation for military service,

not in the ranks, but by becoming commissioned officers, as, if enrolled, they will not be called up by the recruiting authorities for military service under the compulsory provisions of the Military Service Acts, and their obligation to serve (qualified in these ways) is actually exacted from them only if and when it is deemed necessary and right by a committee of their own profession established for the purpose.

There remains the case of the medical man under 41 who does not enrol under the conditions created by the new Military Service Act. He will not have the advantages of Army Council Instruction 485, quoted above; he will be called up by the recruiting officer in his class, and if he does not desire to be taken for general service it will be necessary for him to apply to the local tribunal for exemption. Under Section 7 of the new Military Service Act,¹ which deals with medical men, the local tribunal will refer his case, unless his objection be conscientious, to the appropriate Professional Committee. This Committee will consider any facts brought before it, and will determine whether he is or is not needed in his locality, and will make a recommendation accordingly to the local tribunal. If the local tribunal is advised that he is not needed in the locality it will refuse him exemption, and the military authority will then call him up under the compulsory powers of the Military Service Acts, and the War Office, unless it considers him unsuited for the R.A.M.C., will presumably give him a commission in that corps.

The recommendation of the Professional Committee is binding on the tribunal. It will be seen, therefore, that whether a man has enrolled or not, his case will be decided by one and the same Professional Committee. But as the man who does not enrol will be under the compulsory provisions of the new Military Service Act, and as he has no privileges (not being enrolled) under Army Council Instruction 485, the War Office will make his commission in the R.A.M.C. for the whole period of the war and on the ordinary lines, without any of the special arrangements as to pay, or a twelve-month period of service, or otherwise, that have hitherto obtained in this war for medical men taken into the R.A.M.C.

The position of a medical man over 41 is not affected by the Military Service Acts. It is, however, open for him to enrol, for he is eligible to receive a commission for general service in the R.A.M.C. until he has attained the age of 45, and there can be no doubt that unless he enrolls and so places his services at the disposal of his country if and when required, the position with regard to certain areas will be very difficult, and the calling up of men for service in the R.A.M.C. will involve hardship to the community and to his fellow practitioners. It may be assumed that a sense of patriotism and the spirit of fairness will lead every man from 41 to 45 to enrol; in order that the necessary selection may be made from the widest field possible. Between these ages service is voluntary, and no man over 41 will be called upon, unless he so desires, to give more than one year's service under the undertaking given when he enrolls. The conditions in his case remain precisely as they were before the passing of the Military Service Acts.

The war must be won at any cost. An efficient medical service is an essential part of military organization. Unless a doctor is convinced that he knows how the war can be won without him, he must trust some one to tell him his duty as matters now stand. And the only body which can do this from wide knowledge and in an equitable manner is the Professional Committee of the country to which he belongs.

THE CAMPAIGN FOR CLEAN MILK.

So many valuable lives are being lost in the war that the importance of cutting down our infant mortality to the lowest possible figure is being realized more generally than ever before. Much good work is being done by the medical men in charge of clinics for infants, the managers of schools for mothers, the home visitors provided by municipalities, by the many various associations that exist to improve the welfare of the poor, and by other useful organizations designed to lessen this mortality, which is still notoriously unduly high. Many of the fatal diseases to which infants are prone are due directly to the consumption of impure milk. In the great majority of instances this impurity, or contamination with pathogenic bacteria, is avoidable; the infection of the milk occurs habitually on the dairy farm or in the course of transit from dairy farm to consumer. No medical man can doubt that the dangers to which infants and young children fed wholly or largely on cow's milk are exposed could be enormously reduced by legislative and administrative measures directed to procuring the general supply of uncontaminated milk to the public, and to preventing the supply of impure milk, or milk contaminated with bacteria of all sorts. These observations are, of course, platitudes. But they are worth restating in view of the great importance of the subject and the campaign for clean milk that has been organized by the National Clean Milk Society. This society has recently republished in pamphlet form¹ a series of articles that appeared week by week in the *Observer* at the end of last year and the beginning of this. They were written and published with the hope that they might be the means of stimulating interest in a subject which is of prime importance to the welfare of the country. The condition of our milk supply is bad, and cannot, it is maintained, be much improved until the public clearly understands the relative values of clean milk and dirty milk, and demands and is willing to pay a higher price for the clean milk. The society, which is incorporated, has been formed with the objects of raising the hygienic standards of milk and milk products, and of educating the public as to the importance of a clean and wholesome milk supply. The pamphlet gives an admirable account of what has to be done and how the necessary improvements are to be effected. Accounts are given in general terms of the reforms required in farm practice, in the conveyance of milk, in the licensing of milk dealers, and in other important details affecting the supply and the domestic consumption of milk. The pamphlet might be read with advantage by millions of milk-consumers in this country; it has been written for the layman, and in the form of a cheaper reprint, if that be possible, it should have a very extensive circulation. The problem of obtaining a supply of pure milk is naturally one that affects other countries as well as ours, and has received a great deal of attention in the United States of America during the last quarter of a century with, in many towns, most satisfactory results. In India also it is now being discussed. We have before us an excellent account of the milk problem in Indian cities, with special reference to Bombay,² discussed at length in its scientific, sanitary, economic, and legislative aspects. Much remains to be done in improving the breed of milch cattle in India; on the other hand, it is said that tuberculosis is extremely rare among cows in Bombay and has never been found in buffaloes, while tubercle bacilli have never yet been detected in Bombay milk, so that the elimination of tuberculous cows cannot in India be the difficult problem it has always shown itself in Great Britain. Dr. Joshi's book is full of important facts and

² *The Milk Problem in Indian Cities, with Special Reference to Bombay*. By I. L. Joshi, B.Sc., M.D., Municipal Analyst, Bombay. With a Foreword by J. A. Turner, C.I.B., M.D., D.P.H., Executive Health Officer, Bombay Municipality. Bombay: D. B. Taraporevala, Sons, and Co. 1916. (Demy 8vo, pp. 245.)

figures bearing on the whole subject, and should form a sound basis for the discussion of the practical reforms that are called for in the provision, collection, and distribution of pure milk in India. Here, as elsewhere, the co-operation of the milk-consuming public is essential for the success of any scheme put forward by the Government and municipal or other authorities that may interest themselves in the great milk question.

EPIDEMIC JAUNDICE DUE TO *B. PARATYPHOSUS B.*

PROFESSORS FRUGONI AND CANNATA have recently recorded¹ a small epidemic of catarrhal jaundice among Italian soldiers stationed in the valley of the river Judrio, a tributary of the Isonzo, on the eastern Austro-Italian border. In the course of two months about a hundred cases were seen in hospital. In some instances the jaundice was the only symptom or sign of disease, but in most cases there had been for from two to four weeks diarrhoea (perhaps with slight fever), loss of appetite, and a sense of heaviness or even pain in the epigastrium. This pain was noted in over half the patients, and was attributed to tension of Glisson's capsule of the liver. The jaundice followed on these disturbances after the lapse of various periods of time, and reached various degrees of intensity, as is commonly the case with ascending cholangitis secondary to gastro-enteritis. Mild fever was noted at the onset of the jaundice in a quarter of the patients; the stools were cretaceous in 54 per cent. early in the jaundice, later becoming normal in colour in the usual manner. The authors were not in a position to determine experimentally whether these cretaceous stools were alcoholic or merely fatty, and leave the point unsettled. But by the use of Einhorn's duodenal sound they were able to prove that the secretion of bile was "sufficiently deficient" in the first days of the jaundice, and was normal or even greater than normal during convalescence. Their use of the duodenal sound also showed them that a part, at any rate, of the biliary obstruction in these patients was due to the presence of little blocks of mucus in the thickened biliary secretion. By prolonging the stay of the sound in the duodenum they were able to obtain some bile from it in every instance, although sometimes in very small quantities. Bradycardia was observed in 52 per cent. of the cases, and in some was (*pace* Dr. Mercier) very marked. No tendency to haemorrhage was seen. The liver was enlarged in every case, but not in proportion to the jaundice; the gall bladder was palpable in a few patients, and painful in a few. The spleen was enlarged in 60 per cent. of the cases, and most so in the patients in whom the liver was most increased in size. The etiology of this jaundice was submitted to examination in 43 of the patients by the employment of Einhorn's duodenal sound, blood cultures, and tests for agglutinating power in the serum. The blood proved sterile in all cases. The bile gave cultures of *B. paratyphosus B* in 11 patients and of *B. typhosus* in 1; from the clinical point of view there was nothing to distinguish these 12 patients from the other 36 whose bile proved sterile on culture. The agglutination tests showed that the serum of 15 of the patients agglutinated *B. typhosus* when diluted 1:50, and one when diluted 1:100; all had received antityphoid inoculation. As regards *B. paratyphosus B*, one of the eleven infected patients gave a positive result at a dilution of 1:50, nine at a dilution of 1:100, and one at a dilution of 1:200; of the remaining 37 cases investigated, five gave a positive result at a dilution of 1:50, and one at a dilution of 1:100. None had received antiparatyphoid vaccination; nor did the serum of any of them agglutinate *B. paratyphosus A*. Examination of the faeces showed that in only three instances could *B. paratyphosus B* be recovered out of 43; but this method of

examination was taken up too late in the day for the results to be completely trustworthy. The authors remark that this epidemic of jaundice occurred at the end of an epidemic of "typhoid" fever; they conclude that the infecting bacilli had become attenuated and less virulent, and so produced jaundice rather than a "typhoid" fever. Paratyphoid B fever has been increasingly common in the Italian army; the authors add that abnormal types of typhoid and paratyphoid fevers have often been recorded during the present war, such as apyretic typhoid in Germany (Meyer), and infectious jaundice (Raymond and others) in the Vosges and Tripoli and the Dardanelles, as well as in Italy.

THE IMPERIAL COLLEGE OF SCIENCE.

A LARGE company of representatives of the scientific and technical press were received at the Imperial College of Science, South Kensington, on May 31st by the Right Hon. Arthur Dyke Acland, chairman of the executive committee of the governing body, and, with the professors and other members of the staff, took them round the institution. The college, of which Sir Alfred Keogh is rector, has now as many ramifications as a great tree has roots, but the departments of chemistry, electrical engineering, and metallurgy chiefly engaged the attention of the visitors. Professor H. B. Baker, who occupies the chair of chemistry, said that the scientific investigation carried on at the college had an industrial bias, and the great need at the present moment was for what he described as semi-laboratories, that is to say, places in which scientific research, having passed the initial stages, could be continued on a scale of operation and equipment approximating to that which obtains in industry. Among a score of subjects for investigation already in hand, or to be undertaken as soon as opportunity offers, were the disease-producing organisms of animals from a comparative point of view, economic plant physiology and pathology, and methods of destroying house-flies. Various types of respirators as a means of protection against poisonous gas had been evolved in the college, and also a practicable method of purifying water for the supply of troops. Much attention had been paid also to the manufacture of synthetic drugs; at a time of threatened shortage owing to the stopping of external supplies, the laboratories set to work, and within three weeks the supply of three essential drugs for hospital purposes was assured. Mr. Acland referred to the memorial which has just been presented to Lord Crewe by the professors of the college, urging the importance of securing that a larger proportion of young men in this country should be trained in scientific methods with a view to industrial research. The suggestion is that a grant of a quarter or half a million, in addition to the quarter of a million (as against Germany's million and a half) which the State annually grants to the universities might profitably be used to provide an adequate number of bursaries for secondary-school boys of 16 to 18 years of age, to be followed by the offer of Government scholarships tenable at a university.

CATGUT.

THE Académie de Médecine on May 16th, after discussing a report presented by M. Quénu on May 9th, adopted a series of resolutions as to the manufacture of catgut and as to its sterilization. The resolutions as to manufacture were: (1) That catgut for surgical use should be made only from fresh bowel, and that a clause to this effect should be introduced into all contracts; (2) that special precautions in the selection and treatment of intestine for this purpose should be enforced in slaughterhouses; and (3) that in the factories where gut is prepared, special rooms should be set apart for the preparation of catgut for surgical use, and that the apparatus in them and the training of the workpeople should be improved. The

¹ *Lo Sperimentale*, Florence, 1916, lxx, 25.

resolutions as to sterilization were to the effect that tubes of catgut sterilized by pharmacists should be subject to some outside control, and should bear a label stating the nature of this control and the place of origin of the catgut.

PRISONERS IN GERMAN CAMPS.

How is it that our Government is so ill informed as to the treatment of prisoners in German camps? On April 13th Sir Edward Grey admitted that neither he nor his colleagues had any suspicion of the horrors of Wittenberg, adding that they had no reason to suppose that the state of things was the same in other typhus-infected camps in Germany. Yet the truth might have been discovered from sources easily accessible. An account of the outbreak at Gardelegen by Major P. C. Davy and Captain A. J. Brown was published in our issue of November 20th, 1915, and a summary of Dr. Léonetti's experiences of similar epidemics at Cassel and Langensalza was given in the JOURNAL of March 18th, 1916. These accounts are confirmed by independent testimony quoted in the JOURNAL of May 6th.

If more evidence is wanted we may refer the Foreign Office to Dr. Ribadeau-Dumas's record of his own experience of German prison camps. He is a Paris hospital physician, and his testimony, which is published in *Paris Médical* of May 20th, therefore carries special weight. After a period of detention at Altengraben, he, with a number of other doctors, French and Russian, was sent on February 8th, 1915, to the camp at Stendal. There the prisoners were persecuted in all sorts of ways. The state of things was so bad that the higher authorities seem to have become alarmed, and an order was issued enjoining prudence on those in charge of camps, as "too severe treatment inflicted on the prisoners was likely to tarnish the good name of Germans among neutrals." In consequence, some of the officers strove to undo the evil effects of the previous reign of terror. A delightful example of Teuton tactfulness is given in a story of one of them offering the French prisoners cotton caps bearing the marks of French military hospitals! War is war, and the caps were loot like anything else. On the occasion of some popular festival in the town huge baskets were brought in with much ceremony, and bits of cloth stolen at Lodz were distributed among the prisoners, who were ordered to wear them as cravats in token of German liberality; but no useful thing, such as a shirt or a piece of linen, was ever given. Typhus broke out and the Germans fled, leaving the French and Russian doctors with the sick within a barbed wire enclosure, where the conditions were most unfavourable. Several of the medical men fell victims to the criminal want of forethought of those in charge of the camp. The Government was moved to take action only when the disease began to spread among its own people. Then isolation huts were built, disinfectors and baths set up, and, by way of throwing dust in the eyes of the public, antityphoid inoculations were carried out on a large scale. Ribadeau-Dumas speaks strongly about the food supplied to the prisoners; it was not only deficient in quantity, but extremely bad in quality. At Stendal the staple ration was what was called potato soup, a filthy decoction with herring heads floating in it, and smelling of rotten fish, which the very dogs howled at. Miserable as the food was, the prisoners fought for it. Parcels sent from home were opened and the contents stolen. Punishments in the form of blows, kicks, and short commons were showered on the prisoners; the doctors were placed under arrest without any reason assigned; some were confined to their rooms for months. The lazaretto was barely furnished; the beds were mere frames covered with mattresses of wood shavings and a coverlet. The medicines consisted of aspirin and quinine tablets, tincture of iodine, castor oil and potassium chlorate. There were only a few instruments—a worn-out tongue depressor, two crooked stylets, and a jagged bistoury. The German doctors were, as a rule, rough, sometimes brutal, in their manners; they physicked the patients at haphazard; some were grossly ignorant. Wounds were stitched up with a mattress needle and unaseptized thread; the surgeons did not wash their hands. This description of German surgery may be compared with that

given by Léonetti in his *Souvenirs de Captivité*. Ribadeau-Dumas complains bitterly of the utter neglect with which the sick prisoners were treated. Inspections were a farce. Once they saw a General, to whom they were allowed to speak, but after listening to the recital of their woes, he said that that kind of thing did not concern him, and walked away. At Altengraben, in reply to some complaint, another General merely called them "sagrésgôchons." These are the only occasions on which they had any relations with the higher German authorities. The neutral inspectors they never saw. One day the French prisoners refused the soup, which was unusually bad. They were made to stand motionless in two rows for a couple of hours; they were then placed in a barbed wire enclosure with some sixty prisoners from Wittenberg suspected of typhus. Of many of the worst things Ribadeau-Dumas says that he cannot bring himself to write.

With regard to food, Mr. Tennant stated, in reply to Major Wheeler, on May 3rd, in the House of Commons, that no stated ration was provided by the German Government for British prisoners of war in Germany, but that commandants were instructed, within limits, to make local purchases of food which should afford an average of 85.9 grams of protein, 43.7 grams of fat, and 484.5 grams of carbohydrates, equivalent to 2,762 calories a day. Taking an average of the foodstuffs which appeared to have been purchased, the allowance per day would be approximately 13.8 oz. of breadstuffs, 8.4 oz. of meat, fish, or cheese, and 35 oz. of vegetables. That, he said, was the scale; it was impossible to say that in all cases that was the amount of food given in Germany, but he was informed privately, not officially, that it was carried out very generously. Mr. Tennant has since seen cause to modify this optimistic statement. On May 24th he said that further information, derived from returned prisoners, showed that the German scale was in practice disregarded, with serious consequences to the prisoners, and that he was advised that if it had not been for the parcels of food sent to the men from this country, they would in very many instances have starved. On the same day, in reply to Mr. McNeill, Lord Robert Cecil said that, so far as the Foreign Office knew, all parcels, or almost all, reached the prisoners, but the matter was one which ought to be regarded with grave anxiety as to what might possibly happen in the future.

This is to some extent a reassuring statement, inasmuch as it shows that the Foreign Office, at least, is becoming awake to the facts, and we hope that it will vigorously pursue its inquiries into the state of things in the German prison camps. As a contribution towards them we may call attention to a paper on "The oedema disease of war-prison camps," published by Oberstabsarzt Professor Jürgens in the *Berliner klinische Wochenschrift* for February 28th, 1916. His remarks apply to several prisoners' camps, the names of which he withholds. He states that the clinical picture of oedema and general weakness among prisoners has become very common; its true cause has, he says, often been overlooked, either for want of adequate medical attendance or because the symptoms were misunderstood by the doctors, who had never seen anything like them before, and wrongly associated them with epidemics of typhus and other fevers. The symptoms began with slowly progressive weakness, depression, and distaste for any exercise, culminating in complete incapacity for work. The patient's dull expression, flabby, slightly-jaundiced skin, and pale mucous membranes, showed at a glance how poor his health was; when his face grew puffy and his legs swollen, it became impossible to overlook this condition, but the onset was so insidious that it was often overlooked in its early stages. How inadequate the medical attendance must sometimes have been among the prisoners is shown by Professor Jürgens's words: "It was usually the swelling and pain in the limbs which excited attention, but sometimes even this oedema disease remained unnoticed so long that still worse disturbances developed, which finally led to severe general oedema, to scorbutic conditions, and to the most severe intestinal disturbances, convincing even others than doctors of the presence of a severe disease." In one camp the prisoners were admitted in an emaciated and exhausted condition. Though they remained there a considerable time, and no epidemic broke out, they continued to look feeble and flabby. Early in January they were given work on the land, and after about two weeks

of this employment from 10 to 20 per cent. of them developed swelling of the legs and face and general weakness. Jürgens writes of these manifestations as being beri-beri-like. They more closely resemble those of land scurvy. As they suggested that the prisoners were getting a badly adjusted diet, or were being underfed, some improvements were made in the diet, with the result that no new cases developed; and the feeble and miserable-looking patients were spared further disorders of metabolism. In other camps these beri-beri-like symptoms were, undoubtedly, often associated with epidemics of typhus, dysentery, etc.; but Professor Jürgens is convinced that these epidemics acted simply like manual labour by exhausting the energy of the body, and thus precipitating serious symptoms at a time when the nutrition of the body was already imperfect.

The story, as it is so far known, of the treatment of their prisoners by the Germans throws a strange light on the working of the Teutonic mind. First, the charges relating to Wittenberg were denied, then various excuses were put forward. The latest of these is contained in a White Paper lately issued, which includes a report of a conversation which Mr. Jackson of the United States Embassy in Berlin had with the Inspector General at Magdeburg. The General said that typhus had been practically unknown in Germany before its introduction by the Russian prisoners; that the symptoms were not recognized, and that the German doctors had not known at first how to treat the cases which appeared. The isolation of the camp and the order forbidding the German guards to enter it had been absolutely necessary to prevent a spread of the disease to the city of Wittenberg, where most of the guards had their homes, and as a result of these precautions there had not been a single case among the civilian population. Evidently the philanthropic officer thinks it better that prisoners should die than that a single German should be exposed to infection. This remarkable confession of ignorance and incompetence, to say nothing of inhumanity, throws a fierce light on the boasted "Kultur" which is to bring a new gospel to a world sitting in darkness.

Medical Notes in Parliament.

The New Military Service Act.

THE Military Service Act, 1916 (Session 2) entitled "An Act to make further provision with respect to military service during the present war" received the Royal Assent on May 25th.

Section 1 extends and continues the operation of the Military Service Act, 1916. It enacts that "every male British subject who has at any time since August 14th 1915 been, or for the time being is, ordinarily resident in Great Britain, and who for the time being has attained the age of eighteen years and has not attained the age of forty-one years, shall, unless he either is for the time being within the exceptions set out in the first schedule to the Military Service Act, 1916 (in this Act referred to as the principal Act) as amended by this Act or any subsequent enactment, or has attained the age of forty-one years before the appointed date, be deemed as from the appointed date to have been duly enlisted in His Majesty's regular forces for general service with the colours or in the reserve for the period of the war, and to have been forthwith transferred to the reserve: Provided that steps shall be taken to prevent as far as possible the sending of men to serve abroad before they attain the age of nineteen."

The appointed date (the thirtieth day after the passing of the Act) is June 24th.

Section 2 prolongs expiring terms of service "in the case of men whose time for discharge occurs before the end of the present war not exceeding the duration of the war" except in the case of men who have served for twelve years or more and have attained the age of forty-one.

Section 7 contains the provisions as to exemption of medical practitioners, published last week, as follows:

7. *Provisions as to Exemption of Medical Practitioners.*—Regulations made under the second schedule to the principal Act shall provide for the establishment of professional committees to deal with claims for exemption made by duly qualified medical practitioners; and any application made by such a

medical practitioner on any other ground, other than that of conscientious objection, for a certificate of exemption shall be referred by the tribunal to whom it is made to such a committee in accordance with those regulations; and the recommendation of the committee on the application shall be binding on any tribunal constituted under the principal Act.

Section 12 is as follows:

12. *Transfer to Reserve under Special Circumstances.*—The Army Council may make arrangements, to take effect during the continuance of the present war, for the transfer to the reserve of any member of the regular forces or for the temporary demobilization of any member of the territorial force, notwithstanding anything in any Act or in the terms of his enlistment, in cases where the transfer or demobilization appears expedient in the general interests of the country and the Army Council are satisfied that it can be effected under conditions which will render the man transferred or demobilized immediately available for service in the case of military necessity. Provided that during such period of transfer or demobilization the man shall not be subject to military discipline.

Section 14 is as follows:

14. *Transfer of Officers and Men of the Territorial Force.*—(1) During the continuance of the present war, notwithstanding anything in section seven of the Territorial and Reserve Forces Act, 1907, the orders and regulations for the government and discipline of the territorial force made under that section—

(a) may authorize a man of the territorial force when belonging to one corps to be transferred without his consent to another corps, and may authorize a man of the territorial force to be posted without his consent to a battalion or other body of the regular forces included in the corps to which he belongs or is transferred; and

(b) in the case of an officer or man in the territorial force who is liable to service outside the United Kingdom may, for the purposes of such service, and notwithstanding anything in any instrument defining the conditions of such service, authorize the drafting of any such officer or man to any unit of the territorial force within the corps to which he belongs or to which he may be transferred;

and those orders and regulations shall also provide for the maintenance of the rate of pay of a man who is transferred without his consent to a different arm or branch of the service, except in cases in which it appears undesirable to the Army Council that the rate of pay should be so maintained.

(2) This section shall affect officers or men of the territorial force, notwithstanding that they were commissioned, enlisted, or re-engaged before the date of any order or regulation under this section.

Section 15 gives powers to form corps for more than one county.

Section 16 is as follows:

16. *Provision as to Liability of Territorials to Serve Outside the United Kingdom.*—Where an officer or man of the territorial force has, before or after the passing of this Act, accepted liability to serve in any place out of the United Kingdom, that liability shall continue, notwithstanding anything in the conditions of service, during the continuance of the present war, unless the competent military authority, as defined for the purposes of Part II of the Army Act, otherwise direct.

War.

Mesopotamia.—In reply to Colonel Yate, on May 30th, the Secretary of State for India said that the terms of reference to the Commission appointed to inquire into the medical arrangements of Mesopotamia required it to ascertain and assign the responsibility of individual officers for any inadequacy or failure of relief, or shortage of personnel, equipment, vehicles, or stores. Mr. Chamberlain added, in reply to a supplementary question, that the Government of India had appointed the Commission at his request because he thought it desirable that the facts should be ascertained. He did not consider it well that the Commission should publish an interim report, but that when it did report it should present the whole of the facts.

British Prisoners in Germany.—In reply to Mr. Malcolm, Sir Edward Grey stated on May 25th that the White Paper containing the American reports of British prisoner camps in Germany had been issued that day, and that the text of the agreement under which invalid German and British prisoners of war would be sent to Switzerland, and the categories of diseases that would qualify prisoners for this transfer, would, it was hoped, be laid before Parliament very shortly. The question of the inclusion of civilians in the arrangement between Great Britain and Germany for the internment in Switzerland of invalid prisoners of war not entitled to repatriation was under consideration. There was already an agreement with Germany for the repatriation of invalid civilians.

British Prisoners in Turkey.—In a written reply on May 25th Mr. Tennant said that an agreement had been

reached with the Turkish Government for the reciprocal repatriation of incapacitated prisoners of war under the same conditions as had been in operation for over a year between this country and Germany. It was hoped that the agreement might be put into effect shortly.

Air Raid Casualties in Great Britain.—The Home Secretary stated, on May 29th, that the total casualties caused by hostile attacks from the sea and from the air in Great Britain since the outbreak of war up to the present date were as follows: In the three attacks from the sea 141 persons were killed, including 61 men, 40 women, and 40 children, and 611 persons were injured. In the forty-four air raids 409 persons were killed, including 222 men, 114 women, and 73 children, and 1,005 persons were injured. These figures differed slightly from the totals of those published from time to time, owing to the fact that some persons reported as injured subsequently died, and a few additional cases of injury of a minor character not known to the police at the time were afterwards reported.

Steel Helmets.—Mr. Tennant on May 29th stated that the supply of steel helmets had very nearly reached the number asked for up to the present, and that it was believed that sufficient had been issued for the needs of all the British troops within the zone of shell fire in France. The percentage of head wounds to total wounds in British hospitals in France from February 13th to May 15th, 1916, was 12.35.

Civil Liabilities.—In a written reply to Mr. Hunt, on May 25th, Mr. Hayes Fisher said that the regulations as to a grant not exceeding £104 for relief of home obligations did not at present permit of the scheme being applied to officers.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

LIEUTENANT-COLONEL GEORGE OLIVER MOORHEAD, South African Imperial Force, Nyasaland Contingent, is reported to have been killed in action. He was the eldest son of the late Brigade Surgeon G. A. Moorhead, R.A.M.C., was born in Mauritius, and educated at Malines in Belgium and at Edinburgh University, where he graduated in medicine. He subsequently went out to South Africa, and was practising in the Transvaal when the Boer war began. He was commandeered by the Boers and placed in charge of a field ambulance. After a time he escaped, and, joining the British forces, was present at the battle of Colenso, served throughout the war, and received the Queen's and King's medals. When the present war began he left his practice, joined the Union Defence Force as a combatant, and served throughout the campaign in German South-West Africa, subsequently being appointed to the command of the Nyasaland contingent in East Africa. His younger brother, Brevet-Colonel A. H. Moorhead, I.M.S., was promoted for his service in France, invalided at the end of last year, and died on March 1st.

Captain D. Waterston, Canadian Army Medical Corps, attached to the Canadian Infantry, was reported as killed in action, in the casualty list published on May 29th.

Lieutenant James McC. Johnston, R.A.M.C., has been reported as killed in action. He was the elder son of Dr. Robert Johnston of Dundee, and was 32 years of age. After receiving his early education at the Dundee High School he studied at the universities of Edinburgh and St. Andrews, and graduated M.B., Ch.B. at the latter university in 1913. He held the office of house-surgeon at the Dundee Royal Infirmary for a year, and began practice in Perth. He received his commission in August, 1915.

Died of Wounds.

Quartermaster and honorary Lieutenant H. Maffey, R.A.M.C., was reported as having died of wounds, in the casualty list published on May 25th.

Wounded.

Captain J. H. Aikman, R.A.M.C., temporary.

Captain G. A. E. Argo, R.A.M.C., temporary.

DEATHS AMONG SONS OF MEDICAL MEN.

Grune, Gilbert Dennis, Lieutenant Royal Field Artillery, attached Royal Flying Corps, son of Captain Edward Grune, R.A.M.C., of the Hall, Southwick, Sussex, killed flying on March 13th, while on a reconnaissance as a pilot, aged 22. He was educated at South Lodge, Lowestoft, and at Steyning Grammar School, and had just finished his pupillage with Messrs. Vickers when the war began. The Territorial battery of artillery to which he belonged was then mobilized; he accompanied it to France in November, 1914, and was present with it in several engagements. In 1915 he joined the Royal Flying Corps, qualifying in September.

Howard, Cecil Cunningham, Second Lieutenant Loyal North Lancashire Regiment, only son of Dr. Howard of Upper Norwood, died of wounds on May 23rd, aged 19.

We regret to learn that Dr. Frederick Taylor, President of the Royal College of Physicians, and consulting physician to Guy's Hospital, has received official notification that his son, Lieutenant H. C. N. Taylor, 20th Battalion of the London Regiment, has been killed during the recent fighting in France.

NOTES.

MENTIONED IN DISPATCHES.

In a dispatch dated November 13th, 1915, Brigadier General N. W. Barnardiston, M.V.O., commanding the Tsingtau Expeditionary Force, gives an additional list of officers, non-commissioned officers, and men deserving of special notice, among them being the following medical officers: Major J. A. Hartigan, M.B., R.A.M.C., Senior Medical Officer; Captain G. H. Dive, R.A.M.C., attached to the 2nd Battalion, South Wales Borderers. The list also contains the names of four non-commissioned officers of the R.A.M.C.

England and Wales.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE report presented to the annual meeting of the Governors and General Council of King Edward's Hospital Fund for London last week showed that the total receipts for the year 1915 amounted to £226,779 19s. 5d., of which £12,949 17s. 9d. were contributions to capital and £213,830 1s. 8d. receipts on general account. The income from investments amounted to £97,218 and was larger than ever before, owing primarily to the receipt of a full year's income from the first instalments of the Wernher legacy. The total loss to the income of the year through failure to pay interest or dividends since the war began amounted to less than £800, due to non-receipt of interest or dividends on certain securities acquired by the Fund as gifts or legacies from various donors. The Fund held on December 31st a large amount of war stock obtained partly by investment and partly by conversion of consols received from various executors in the past. The realized depreciation of £6,046 on trustee stocks due to this conversion was very nearly balanced by a realized appreciation on non-trustee investments, leaving a net realized depreciation of only £62. The Fund had already received £100,000 from the residue of the estate of the late Dowager Lady Wilton, and it was estimated that another £50,000 would accrue. The adoption of the accounts and of the annual report of council was moved by the Speaker of the House of Commons, who was in the chair, and carried. The total sums distributed among hospitals, convalescent homes, and consumption sanatoriums during the last ten years was £1,484,750, and since the foundation of the Fund £2,098,416. During 1915 the amount allocated was £133,500, of which £111,775 was granted in aid of general maintenance, £5,750 to the reduction of debts on maintenance account, and £15,975 towards schemes of buildings or improvements; the supplementary grants followed the same apportionment. The Fund had continued to encourage hospitals in the policy of postponing all schemes of capital expenditure not already in hand at the outbreak of war or exceptionally urgent. An increased grant to sanatoriums had made it possible to reserve 52 beds for the use of patients in London hospitals, as against 44 last year. The total amount spent on administration was at the rate of £1 8s. 3d. per cent. of the total amount received, as compared with 12s. per cent. in the previous year. The percentage for the whole period since the inauguration of the Fund was £1 4s. 7d. Sir William Church presented a report from the Distribution Committee on the expenses of the Bland-Sutton Institute of Pathology at the Middlesex Hospital. The negotiations with the hospital had, he said, been of the most friendly character, and the committee

recommended the acceptance of the scheme of apportionment between hospital and medical school for the year 1915 as satisfying the conditions attached to the grants made by the Fund. The report was seconded by Sir John Tweedy and carried unanimously. A report of the Convalescent Homes Committee, recommending that under certain circumstances a special application from the National Association's Sanatorium at Benenden for an emergency grant of a limited amount should be granted, was moved by Sir William H. Bennett, seconded by Sir W. Watson Cheyne, and carried.

In acknowledging a vote of thanks, moved by the Chief Rabbi and seconded by Viscount Mersey, the Speaker said that it must be expected that as the war continued the margin of any eleemosynary funds available for the general charities of the country must shrink to a considerable extent. Fortunately, the Fund had got through its difficulties extraordinarily well, but next autumn or a year hence a considerable shortage might be shown.

THE HOUSING OF A VIRILE RACE.

We called attention recently to two inquests held by the coroner for Southwark with regard to the death of a woman and a boy in the Tabard Street area. It appears that in February it was considered that circumstances arising out of the war justified the London County Council in not proceeding with the execution of the scheme, but the Local Government Board has now issued an order permitting a modification of the scheme so as to enable the Council to demolish some 268 buildings, in addition to those already demolished. The chairman of the Working Classes Committee has informed the Council that the total number of buildings demolished, or about to be demolished, is 420. The original scheme proposed the demolition of 503 premises, occupied by about 2,600 people. It was hoped that accommodation for 600 people would be found in September.

Correspondence.

THE HORRORS OF WITTENBERG CAMP.

SIR,—When you were good enough to publish, in your issue of April 22nd, a letter from me upon the above subject, my intention was to bring a resolution before the annual meeting of the Laryngological Section of the Royal Society of Medicine requesting the Council of the society to delete the names of all Corresponding members of German birth from the roll of the section as an outward expression of disgust with the treatment, or rather, lack of treatment, meted out to our helpless and fever-stricken prisoners of war at the hands of their professional *confrères*. A resolution to this effect was sent by me to the honorary secretary of the section, but on submission to the president of the society was held by him to be *ultra vires*. I accordingly modified the original, and sent up a fresh resolution to the secretary of the Otological Section for discussion at the annual meeting upon May 19th, couched in the following terms:

That the members of the Otological Section of the Royal Society of Medicine desire to place on record their sense of abhorrence and disgust at the conduct of Oberstabsarzt Dr. Aschenbach and his colleagues in their abandonment of British prisoners of war during the epidemic of typhus fever at the Wittenberg prisoners of war camp, and request the Council of the Royal Society of Medicine to take such steps as they in their judgement may think fit to emphasize the feelings of indignation shared by members of the British medical profession.

This resolution was accepted as in order by the President of the Section, Dr. Albert Gray, Glasgow; was proposed by myself, seconded by Mr. Richard Lake, and supported by Dr. Watson-Williams.

After a somewhat prolonged and pointless discussion the resolution was put to the meeting and lost—nine members voting in its favour, thirteen against.

The majority of the members present at the annual meeting of the Otological Section were therefore in favour of making no protest whatever against German barbarity to those typhus-stricken prisoners of war who in their day of health and vigour had done what lay in their power to defend our hearths and homes. *Hinc illae lacrymae*.—I am, etc.,

Manchester, May 28th.

WILLIAM MILLIGAN.

"THE SOLDIER'S HEART."

SIR,—In a letter published in the BRITISH MEDICAL JOURNAL of May 20th Sir James Barr refers, in a somewhat scathing manner, to Dr. Florence A. Stoney as "a lady of whose existence I have only been aware so recently as January 22nd, 1916," and he advises her to read "more extensively and accurately."

Without wishing to be discourteous to Sir James Barr, the same advice may be tendered to him.

Dr. Florence Stoney has an assured position among English radiologists, and read an important paper on the x-ray treatment of Graves's disease at a meeting of the British Medical Association held at Liverpool in 1912. Since that time she has been steadily working at the subject and is at present doing valuable work at a military hospital in London. In the face of these facts there seems to be no excuse for Sir James Barr's ignorance of Dr. Florence Stoney's existence prior to January 22nd, 1916. —I am, etc.,

London, W., May 23rd.

ROBERT KNOX.

HOW MEDICAL WRITINGS MAY BE GIVEN A MARKED DEVELOPMENT.

SIR,—It is gratifying to find Dr. Mercier's unjustified condemnation of the use of the words "marked" and "develop" in medical literature set at defiance by Dr. Bramwell.

Why is it incorrect to employ "marked" as an intensive to lend emphasis to a substantive or phrase, as Dr. Mercier would have us believe? Has it not been used in this sense by good English authors, and gained general acceptance? Surely Dr. Mercier's logic has run amuck when he contends that "marked" is used by writers as equivalent to slight or scanty!

The protagonist who is so jealous of the legitimate employment of words ought to have adduced some definite instances in which the much maligned adjective had been used with such an inverted meaning by a sane author.

Moreover, the scholarly "M.D." who sympathizes with Dr. Mercier in his plea for greater clearness in medical writings, and who deprecates slipshod speech, would be well advised to deliberate carefully before espousing the cause of a literary critic who, like Dr. Mercier, introduces weird and uncouth expressions in his correspondence.—I am, etc.,

Glasgow, May 30th.

I. H. LIPETZ, M.B., Ch.B.

THE MEDICAL OFFICERS, MERCANTILE MARINE.

SIR,—The suggestion made by Surgeon-General Evatt that ship's surgeons should be allowed to apply for commissions in the Royal Naval Reserve seems a good one.

He appears, however, to be somewhat "at sea" with regard to the functions of port sanitary medical officers. The duty of verification of the status and of approving the appointment of ship's surgeons lies not with the port sanitary authority, but with the Emigration or Shipping Department of the Board of Trade. As a matter of fact, all such appointments are approved at the port of clearance of passenger ships, except in very exceptional cases, when the surgeon has had to join the ship at the last moment, and then his credentials are examined by the Board of Trade emigration officer and submitted by him to the medical officer of the Board of Trade at the final port of call in Great Britain.—I am, etc.,

Plymouth, May 25th.

CHARLES J. COOKE, M.D., M.Ch.

The Services.

HONOURS.

COLONEL J. SMYTH, I.M.S., has been appointed an Honorary Physician to the King, vice Surgeon-General J. Pinkerton, deceased, February 12th, 1916; and Colonel J. Crimmin, V.C., C.B., C.I.E., I.M.S., vice Surgeon-General C. E. McVittie, deceased, February 18th, 1916.

EXCHANGES.

LIEUTENANT R.A.M.C., Regimental M.O. France, wishes to exchange appointment with officer in base hospital, casualty clearing station, ambulance train, or barge. C.C.S. preferred. Address, No. 2100, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

M.O. to Divisional Train, Army Service Corps, probably at home for some time, desires immediate exchange with M.O. in 50th Division abroad.—Apply No. 1950, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Obituary.

SIR JAMES F. GOODHART, Bt., M.D., LL.D.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

THE announcement of the death on May 28th of Sir James F. Goodhart will be received with poignant regret by a very large number of friends and old pupils. Few men were more popular in medical London and in the school for which he worked so long, and few physicians of his day attained a wider and more solid success both among the profession and among the public. This success was due primarily, no doubt, to the manner in which he trained himself through pathology for clinical work, but it was largely due also to his broadmindedness, which was reflected in his open, friendly, genial manner. Emphatically he was a man not spoilt by success.

James Frederic Goodhart was the son of Alfred Harrington Goodhart, physician, of Camden Road, N.W., who married Elizabeth Wilkinson, daughter of Alexander Goudge, of Sutton Place, N.E. He was born in London on October 24th, 1845, and was educated at Epsom College. He entered Guy's Hospital medical school in 1864. He did well as a student, winning the gold medal for clinical medicine in 1867. In the following year he took the diplomas of M.R.C.S. and L.R.C.P., and in 1871 graduated M.B., C.M. with highest honours at the University of Aberdeen. In 1873 he took the degree of M.D. in the same university, which twenty-six years later gave him the honorary degree of LL.D. In 1872 Goodhart was appointed surgical registrar and in 1874 medical registrar. After his election in 1877 to be assistant physician to Guy's Hospital, he became demonstrator in morbid anatomy, and pathology occupied his interests very much. He worked in the *post-mortem* room for about thirteen years, and when he became physician to the hospital in 1886 he lectured on pathology in the medical school. He resigned the office of physician in 1898 and was appointed consulting physician in 1899.

In 1871 Sir William Flower, Conservator to the Museum of the College of Surgeons, reported that the single assistant in the museum had proved insufficient, owing to the great advances in the science of pathology, and recommended the College to secure the services of a pathologist who held some special appointment at a medical school, so that the wants of the pathological collection in the museum could be supplied from the material at hand in a general hospital. Goodhart of Guy's was just the man for the place; indeed, the council had him in mind when the new appointment was suggested. Accordingly, Mr. James Lidderdale being appointed as anatomical assistant, Goodhart was unanimously chosen pathological assistant in the museum. He held the post with great distinction for six years. In 1875 he was directed to prepare a new supplement to the pathological catalogue; but in 1877, mainly owing to his appointment as assistant physician to Guy's Hospital, he was compelled to discontinue his valuable assistance in the museum, but he undertook to complete the supplement, at which he had worked very hard all through the years during which he had held the appointment. This supplement was concluded in 1879, and the council thanked Goodhart for the great care he had taken in its preparation. As it was found that there was a multiplicity of supplements in the museum, it was, after mature deliberation, decided that the interests of those who studied the collection would be best consulted by the issue of an entirely new edition of the whole catalogue. This was so great an undertaking—the collection then containing upwards of 5,000 specimens—that even its commencement might have been delayed for an indefinite time but for the fortunate circumstance that Sir James Paget, the author, with Stanley, of the first edition (1846-49), was chairman of the Museum Committee, and undertook with the greatest enthusiasm the preparation of the new catalogue, with the co-operation of Goodhart and Mr. Alban Doran, his successor as pathological assistant in the museum. The latter gave place to Sir Frederic Eve, elected pathological curator in 1881. The new edition of the catalogue was completed in 1885. Goodhart, ever generous, wrote for the author of the *Life of Sir James Paget* a most graceful eulogium on the great surgeon's zeal in working hard, week after week, in

the museum, with his two assistants until the new issue was sent to the press.

Goodhart joined the staff of the Evelina Hospital for Children as house-surgeon when it was first opened in 1869; in January, 1875, he was appointed physician to out-patients, and from 1881 to 1888 held the post of full physician, being placed, after his retirement, on the consulting staff; he always maintained his interest in the diseases of children. His book entitled *The Student's Guide to the Diseases of Children*, first published in 1885, quickly attained success. In writing it his object was to treat of the diseases incidental to childhood or such aspects of disease as appeared to be so peculiar to or pronounced in children as to justify insistence on them—not to write one on general medicine. For instance, in dealing with pneumonia and bronchitis, he gave no minute description of physical signs; in heart disease no consecutive account of such general symptoms as are common to all ages of life. He took for granted that the student already possessed some knowledge of general medicine, and he dwelt on such points as belonged peculiarly to childhood.

A second edition was called for in 1886 and a third in 1888. This popularity has been maintained, and the tenth edition was issued in 1913. The book was translated into French, and an American edition was edited by Dr. Louis Starr. The book well merited success, for in its first edition it was the work of an accomplished pathologist who had had large clinical experience. This character has been maintained during the later editions, in the preparation of which Goodhart was assisted by Dr. G. F. Still, and there are few, if any, books published in any language which equal it as an introduction to the subject.

In 1891 Goodhart delivered the Harveian lectures before the Harveian Society of London on "Common neuroses, or the neurotic element in disease and its rational treatment." He printed them in a small volume in 1892, and a second edition was called for in 1894. The review of that volume in this JOURNAL said that the lectures were charming in this sense—that the lecturer took a broad and humane view of his subject, presented it in a winning style, and carried the reader captive by his helpfulness and enthusiasm, coming out of the sphere of abstraction, and taking men and women by the hand as he found them. Who wrote these words in 1894 we do not now know, but, whoever it was, he caught the characteristics of Goodhart both as a man and a physician, and happily expressed the nature of those qualities which won him so high a place in the hearts of his fellows and the esteem of his profession. The book is full of human interest, common sense, and practical advice. It shows its author as one who set to work to remove causes. There is no more difficult class of patient to treat successfully than those suffering from an excess of introspection, an attitude of mind constantly on the look-out for signs of disordered organs, which magnifies out of all reason any sign which it finds and is ever ready to imagine some which it cannot discover. Thirteen years' work in morbid anatomy and pathology gave Goodhart the right to say that there is and always will be a large amount of functional disease. He understood the neurotic type thoroughly, and his recommendation to treat the causes of the neuroses, and especially to give advice adapted to the abnormal mental condition present in so many of these cases, and not to give drugs designed to remove the bodily symptoms, is as sound to-day as ever it was. Very probably if he could have been persuaded within the last few years to undertake a new edition, the growth of his experience would have required him to re-diagnose some of the ailments described in 1894 as neuroses; but the book remains one well worth reading to-day.

Goodhart's official connexion with the British Medical Association began in 1883, when he was secretary at the annual meeting in Liverpool of the Section of Pathology and Bacteriology; he was vice-president of the same section at the annual meetings at Brighton in 1886 and in London in 1895. He was president of the Section of Diseases of Children at the annual meeting in Bourne-mouth in 1891, and in 1901 at the annual meeting at Cheltenham delivered the Address in Medicine. He preached in a specially entertaining form the lesson of individualism in treatment, contrasting this with the work

of State medicine, which was concerned with influences that act on large classes, whilst the practitioner's work required the most careful investigation of individual tendencies without which his practice could not really be successful.

Goodhart became a Member of the Royal College of Physicians of London in 1875, and was elected a Fellow in 1880. He acted as examiner in medicine for four years, and served as Councillor and Censor. In 1885 he gave the Bradshaw lecture. Mahomed, his senior colleague at Guy's Hospital, had been selected to deliver it, and had chosen as his subject "Morbid arterial tension." After Mahomed's untimely death Goodhart was called upon to take his place. He adhered to the subject chosen, but had he selected it himself he could not have given a more brilliant exposition of the state of knowledge and opinion at that day. Twenty-seven years later (in 1912) he was Harveian orator. There was something of pathetic interest in the subject he chose—the passing of morbid anatomy—for Goodhart's youth was given to morbid anatomy; but it was in no spirit of depression or regret that he spoke. On the contrary, he showed himself an enthusiastic exponent of new ideas and new methods. The outcome of his survey, he said, seemed clearly to be "experiment, and ever more experiment. We come, indeed, back to Harvey's teaching: to search out the secrets of Nature by such means. . . . The continuity of life itself becomes an experiment. . . . All powerful, even heroic attempts, to cure disease, what are they all in their use but experiments? . . . It is certain that the future triumphs over disease will only unfold themselves to an ever-widening horizon that embraces all the latest advances of physical science as they bear upon the function of living. Yet would the possibilities seem to be limitless."

Goodhart was an effective speaker; he possessed also the pen of a ready writer and contributed much to medical periodical literature. He published about thirty papers in the *Guy's Hospital Reports* on a great variety of subjects, wrote articles for the New Sydenham Society's *Atlas of Pathology*, and contributed an article on acute and chronic Bright's disease to Keating's *Cyclopaedia of Diseases of Children*, and articles on influenza and asthma in *Albutt's System of Medicine*.

Goodhart received his baronetcy in 1911 on the occasion of the coronation of King George V. He married in 1879 the daughter of Mr. William Bennett, J.P., of Ashgrove, Hereford. Lady Goodhart died in February of last year. He is succeeded by his elder son, a barrister; his second son is a member of the medical profession, who has followed in his father's footsteps by occupying the post of Douglas demonstrator of pathology at Guy's Hospital.

Dr. FREDERICK TAYLOR has been good enough to send us the following appreciation:

As a schoolfellow, fellow-student, and colleague of Sir James Goodhart, I should like to say a few words in appreciation of a very old friend.

At school he was always well to the front, and was very popular with his schoolfellows, cheerful, good-tempered, diligent, but not neglectful of the value of recreation. As a medical student he proved to be exceedingly keen in the pursuit of knowledge, and soon took a prominent position among his fellow-students. He had taken a prize at the entrance examination in school subjects, and in his second and third years he took prizes in the subjects of the year's study, including the Treasurer's gold medal for medicine. Soon after his qualification he was appointed house-physician, a post which had recently been created at Guy's Hospital, and involved the care of all the medical beds, corresponding indeed to the position of sole resident medical officer. After this he was appointed the first resident medical officer to the newly opened Evelina Hospital for Sick Children. To this successful career there was still one thing wanting—namely, a university degree, and Goodhart went to Aberdeen University and there graduated with highest honours and special honours for a thesis on artificial tuberculosis, which was published in the *Edinburgh Medical Journal*. He now returned to Guy's Hospital and his future was ensured by his appointment on the staff, first as surgical registrar, and later, in turn, as demonstrator of pathology, medical registrar, assistant physician, and physician.

Goodhart was eminently successful as pathologist and as clinical physician. He was for a time pathological assistant at the Royal College of Surgeons, and contributed numerous specimens to the Pathological Society. While waiting for an appointment as assistant physician at Guy's, he was elected to the active staff of the Evelina Hospital, and renewed there the opportunity for the study of children's diseases which he turned to such good purpose in later years.

I must leave it to his pupils to speak of his qualifications as a lecturer or clinical teacher; but I can say that he was eminently successful, and that his acuteness of observation, deep interest in any pathological detail, sympathetic insight, wealth of suggestion, and powers of illustration by simile and metaphor, must have made his lectures and clinical teaching as interesting and valuable to his student audiences as were his conversations and writings to those of more mature age.

His one book was his *Diseases of Children*, which, though small at first, exactly met the needs of the practitioner at that time, and has gradually increased in bulk as edition after edition has come out. But it is, perhaps, in his several articles, lectures, and essays that Goodhart's characteristics are best shown: they are full of evidence of close observation, of new points of view, of pathological speculation, of racy and humorous passages; and are frequently endowed with titles which themselves are full of promise of good and useful things to come. It is only within the last few weeks that two such papers have appeared in the pages of the medical press. But, after all, Goodhart's great success was in private practice. Comparatively young, behind a brass plate in Finsbury Square, he made in his first year a decided success; on his change to the West End, in Weymouth Street, and afterwards in Portland Place, his opinion was extensively sought, and he continued in active practice to within a few months of his end. He was extremely popular with patients and doctors. He was genial, friendly, sympathetic, without any of the formality or ceremonial that is apt to be associated in the mind of the public, whether rightly or wrongly, with the idea of the consulting physician; while his useful hints for treatment and capacity for seeing new features or new associations in what to others might be but ordinary cases would always be an attraction to the doctor with whom he was consulting.

He made many friends, and true friends; and few of those who have once known him can feel anything but the deepest sorrow that he has been taken from us now.

Mr. C. H. GOLDING-BIRD writes:

The unexpected end of an honoured and valued life has taken the profession by surprise, for six weeks ago Sir James Goodhart was at his usual work, but now his place will know him no more. To those who have been long intimate with him, the surprise perhaps is rather that he should have reached life's limit—three score years and ten. I well remember, at the beginning of his professional career, his saying to me that he would have to work very hard to provide for his wife and young family, since no life insurance office would even look at him, and that he must therefore depend entirely upon his own efforts, and get on quickly. This, too, was one incentive that concentrated his whole attention upon his profession, but it was by no means the only one; he had from the first a deep love for his profession, with a strong desire to advance its objects to the best of his ability, and to be of service to his fellow-man. He felt the responsibility of the life he had undertaken, and, conscientious man that he was, he never let anything turn him aside from the goal he set before himself. Not a strong man, physically speaking, Goodhart was a living proof that hard work of itself does not kill, and as a good man, in the highest sense of the word, he knew how to keep life's worries at a distance, and his happy disposition, of which his face was an index, was, I think, no small element in his success, both with his patients and his professional brethren.

Not unduly optimistic, he nevertheless always looked on the bright side of things, and his cheery manner has upheld the despondent spirits of many a patient.

Occupied hourly with his professional duties, he yet never complained of overwork, but surrendered himself ungrudgingly even to the most untoward professional call; he was absolutely indefatigable in the discharge of duty.

Though, perhaps, not so scientifically trained as some of his contemporaries, he was nevertheless a great investigator, caring to take nothing on trust that he could confirm for himself, and was continually trying to clear up doubtful points, especially in the matter of pathology, as his early writings show. To this end his personal comfort was, as a young man, laid under contribution, and I well remember, in the early years of the clinical thermometer, and when Goodhart was house-physician at Guy's, his remaining one cold morning, in the depth of winter, in his cold bath, to discover what effect would be produced upon his body-temperature, he watching the thermometer the while!

As a teacher in the hospital he was most successful, and his early retirement was a great educational loss. It was in the pathological department that he was particularly brilliant, where by his accurate method of observation of every minute particular he soon taught others to keep their eyes equally open, while his explanations of what the *post-mortem* room revealed were as sound as they were lucidly communicated; his class in this department was always fully attended. Of his methods in the wards his medical colleagues knew more than I, but I can speak to his untiring industry, his patient investigation of every case—slighting nothing; and his clinical class, whilst receiving the highest teaching, received it also in a very clear and assimilable manner. Goodhart made everything clear, and the most backward student could hardly fail to follow him.

The demands on his time made by an immense private practice prevented Goodhart—even if he had had the desire—from taking his share in the public duties that fall to the lot of many, but he fulfilled his own ideal in the vast amount of good he did professionally and unprofessionally to his fellow-man. He will always be remembered as one of our greatest and most successful consulting practitioners in medicine.

Dr. C. H. HARTT (Greenwich) writes:

It is just thirty-six years since I first met Sir James Goodhart at a *post-mortem* examination of some medico-legal interest, and I was much impressed by his power of imparting knowledge. In the sick-room by the bedside he was at his best; always cheerful and bright, he gave comfort to those with whom he came in contact. If anything, he erred by being too optimistic, but in the goodness of his heart he desired to give hope to the patient and relatives. He was a hard worker in the true sense of the word. In the old days, before the motor car, he would travel many miles by train and cab within the metropolitan area (often without a meal) to fulfil his numerous engagements, and, being susceptible to cold of an influenza type, laid the foundation of a certain delicacy, which attacked him in the months of winter and spring. He never spared himself, and would come down at any hour to see a member of the profession or one of his family, always with a cheerful spirit.

He loved a joke, and I shall always remember his merry laugh. He was a great lover of flowers and the beauty of the country. The loss of his wife quite overpowered him, and he was never the same man after her death. The last time I saw him was in March, and I found him much depressed at the loss this year of so many friends during the war. His name will remind us of one who was kind of heart and always tried to do good.

A former pupil and colleague writes:

The death of Sir James Goodhart will bring to a veritable host of professional friends a keen sense of personal loss. That so busy a practitioner, who throughout his life scarcely ever allowed himself any social relaxations, should have attracted and held such an army of devoted friends can only be explained by his strikingly sympathetic personality. Large numbers of medical practitioners who had for Goodhart the warmest affection had never seen him or spoken to him except in formal consultations. The personal magnetism which gave him such exceptional powers as a physician and brought to him so large a share of the consulting practice in this country attached his professional colleagues to him as firmly as his patients. One is almost tempted to believe that many consultations with Goodhart were arranged as much to afford the practitioner

the pleasure of the personal interview with the consultant as to secure for the patient the benefit of his professional advice. There was never any doubt, however, that the patient would be satisfied too. He would come away confident that the kindly physician had had a full understanding of the case and a proper sympathy with the sick man's own peculiar point of view. No wonder that so universally popular a physician should at one time have been the busiest medical consultant in London. It must not, however, be thought that, in laying such stress on Goodhart's personal charm of manner and sympathetic disposition, it is suggested that it was upon these alone that his professional success depended. At the moment when one is feeling acutely the pang of separation caused by death it is those features in our lost friend upon which we prefer to dwell. A busy general practitioner, with an intimate practical experience of most of the prominent consultants, said the other day, "What struck me most about Goodhart as a consultant was that he was always right." The present writer, who was in constant touch with him in his work in the wards of Guy's Hospital, can well believe this to be true. When every fatal case comes to examination in the *post-mortem* room, as is the custom in hospital practice, the physician's power of accurate diagnosis is put to a severe test. Goodhart, who in his younger days as demonstrator of morbid anatomy had a very great experience of *post-mortem* work, had later a high reputation amongst his hospital colleagues for accurately forecasting the pathological changes that would be found in the cases for which he had been responsible during life. In his Harveian Oration at the College of Physicians in 1912 Goodhart spoke regretfully of the "passing of morbid anatomy." There is no doubt that he laid the foundations of his own diagnostic skill by his industrious work in the dead-house. The *Transactions of the Pathological Society* from 1872 to 1886 give evidence by the numerous contributions they contain from his pen of the interest he took in this subject. It was in this work perhaps more than in purely clinical medicine that Goodhart made his mark as an original observer. The addresses and lectures on clinical subjects which he gave before numerous medical associations and societies in more recent years attracted the attention of the profession more on account of their sound common sense and the profound knowledge they displayed of human nature, than by reason of the original clinical observations they contained. Perhaps he, in clinical medicine, never quite saw the wood for the trees. In dealing with the individual patient nothing escaped his attention, and as a teacher his most valuable work was undoubtedly done in setting his pupils the example of thorough and painstaking investigation by inquiry as to every function and by physical examination of every accessible organ. Less experienced students, accustomed to the spoon-feeding which has, alas! become so prominent a feature of medical education, were bored by the prolonged investigations of which they often failed to grasp the point and missed the didactic methods whereby other teachers helped them to pass their examinations. For advanced students and for men already some time in practice a visit to the wards with Goodhart was always an experience full of interest and profit.

In tackling a troublesome patient Goodhart was no doubt at his best with a cross baby. His experience as physician to the Evelina Hospital for Sick Children provided him with his only temptation to become a specialist. For himself he hated the term "specialist," and used to warn his juniors of the danger he early recognized in accepting the position, when a mother told him how she had at first resisted her doctor's advice to call him to her baby because she understood he was a specialist for children between the ages of 6 and 7.

In his relations with his patients as with his friends Goodhart was a confirmed optimist, and managed to inspire nearly all whom he met with his own hope and cheerfulness of spirit. He worked right up to the end, and to the very last was busy brightening the lives of others. The death of his wife in February of last year was a very severe blow to him, and about the time of the first anniversary of the sad event the early and insidious symptoms were noticed of the fatal illness to which he succumbed early on Sunday morning, May 28th, at the age of 70.

Medical News.

SIR THOMAS BOOR CROSBY left estate of the value of £38,905, the net personalty being £18,155.

DR. ANICOT, professor of clinical ophthalmology in the medical school of Rennes, has been killed at his post near Verdun.

At the meeting of the Central Midwives Board on May 18th, when Sir Francis Champneys presided, certain amendments to the revised rules suggested by the Local Government Board were approved by the Board.

MRS. MARY SCHARLIEB, M.D., will give a course of three lectures on "Inherited disease in children" at 8 p.m. on Wednesdays, June 21st, June 28th, and July 5th in the Robert Barnes Hall, 1, Wimpole Street, by the kind permission of the Royal Society of Medicine. The lectures will be illustrated by the epidiascope; there is no charge for admission.

We are asked to state that the price of the Moseley grooved motor covers has been reduced approximately 10 per cent., and of Moseley tubes $7\frac{1}{2}$ per cent. The price of the steel-studded covers of the same firm has also been reduced. The tyres, we understand, are of British manufacture.

THE Royal Sanitary Institute offers a prize of £50 and its medal for the best thesis setting out a complete and practical scheme for maternity and child welfare work suitable for adoption by local authorities. The thesis must be delivered on or before September 1st, 1916, to the Secretary of the Institute, 90, Buckingham Palace Road, London, S.W., from whom further particulars can be obtained.

THE annual meeting of the School Medical Service Group of the Society of Medical Officers of Health will be held on Saturday, June 10th, at 3 p.m., at 1, Upper Montague Street, Russell Square, London, W.C. Although many school medical officers have already answered their country's call, and others are doing extra duties till their turn comes, the honorary secretary, Dr. Arnly Ashkeny (Sunnyside, Basingstoke), hopes that as many as possible will attend this annual meeting, where the relation of the group to the parent society and other bodies will be considered, reports received, and officers elected.

AN important sale of books at Sotheby's Rooms last week was that of Dr. G. W. Steeves, formerly of Liverpool and recently of Cavendish Square, London, of whom an obituary notice was published in our issue for December 18th, 1915. His choice and valuable library was the collection of a lifetime. It was strong in very rare and first editions of writers of the sixteenth, seventeenth, and eighteenth centuries, notably of the Elizabethan poets—Spenser being well represented, as also Beaumont and Fletcher, and Ben Jonson, as well as Herrick, George Herbert, Dr. Fuller, Dryden, Drayton, Dorne, and Davenant; Sir Thomas Browne was represented by four rare issues of the *Religio Medici*. A fine collection of works by or relating to Lord Bacon—about 100 volumes—was sold in one lot for £450 to Mr. G. D. Smith, bookseller of New York, who also became the possessor of many of the more valuable items, such as Shakespeare's Poems, original edition, 1640, at £190, and the Second Folio Shakespeare at £80. The sale realized £2,555.

THE annual meeting of the British Dental Association will be held in the hall of the Royal Society of Medicine, 1, Wimpole Street, W., on June 15th, 16th, and 17th, and will be almost entirely devoted to the subject of war injuries and gunshot fractures of the jaws. The co-operation of distinguished surgeons and dentists of our own and allied countries has been invited. The subjects for papers and discussions are: On Thursday, June 15th, at 2.30 p.m., "Early treatment of jaw injuries." On Friday, June 16th, at 10.30 a.m., "Appliances and splints" (openers: Mr. M. F. Hopson and Mr. J. E. Spiller); at 2.30 p.m., "Restoration of lost portions of the jaw by surgical means." On Saturday, June 17th, at 10.30 a.m., "Treatment of ununited fracture and malunion" (Mr. J. F. Colyer), and "Diet, massage, and dynamic exercises" (Captain Holt, R.A.M.C.). An introductory address will be given by the President (Mr. W. H. Dolamore) on Thursday afternoon. On Friday afternoon, June 16th, at 4.30 p.m., Lieutenant Derwent Wood, A.R.A., will demonstrate his methods of making and casting masks for facial wounds, as adopted by him at the Wandsworth War Hospital. Demonstrations will also be given by Mr. H. Baldwin and Mr. G. Brunton. An exhibition of appliances, splints, models, etc., has been arranged, and contributions are expected from war hospitals in this country and in the war zone.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2651, Gerard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Atiology, Westrand, London*; telephone, 2650, Gerard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2654, Gerard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

ANSWERS.

TREATMENT OF TOXAEMIA IN MUCCOUS COLITIS.

MEXICAN replies to "Indican" (May 20th, p. 744) who asks suggestions for treating old toxæmia due to mucous colitis and chronic ischio-rectal abscesses: With suitable diet and rest a trial of yeast is suggested. Pressed yeast for baking may be used in 5 to 10 per cent. solution of cane sugar in tepid water. Clear out bowel and abscesses by warm enemata night and morning and then introduce and leave in 5 to 10 oz. of solution-carrying yeast the size of a bean in suspension. See that it gets well into the sinuses. Give by mouth oatmeal stout in wineglassful doses before meals. Get stout in screw-capped quart bottles, and after taking the first dose put into the bottle two teaspoonfuls of sugar, which in summer excites development of yeast residue. An actively fermenting liquor (in which no known pathogenic organism can live) is thus administered, and is usually laxative and cleansing to mouth, stomach, and bowels. The opening of the bottle for administration prevents excessive gas pressure. One or two peppermint lozenges can be sucked after each dose, and occasional use of a mixture of chalk and sod. bic. each 3iij, spt. menth. p. 5j, ag. chlorof. ad 3viij, relieves flatulence. A sedative at night is often required, and 5j syrup codeinae containing $\frac{1}{10}$ grain hyoscyne hydrobrom. is recommended for sleep, and for attacks of colic it may be given with the chalk mixture.

LETTERS, NOTES, ETC.

BROMIDES AND EPILEPSY.

DR. G. V. FIDDIAN (Place Mara, Rio Berbic, B.G.) writes: After reading the correspondence in your columns some months ago on the expediency of administering bromide to chronic epileptics I commenced the experiment of withholding the drug from certain groups of cases in the Public Lunatic Asylum. All went well until the advent of the rainy season, when these cases developed fits in increasing number. Our head warder, who has had thirty-five years' experience, assured me that with the rainy season the incidence of fits among our epileptics was always increased. May I put forward the following hypothesis? Muscular exercise has this in common with the action of bromides, that both cause certain changes to occur in the motor neuron end-plates. Since rainy weather can be foretold by a large percentage of sufferers from chronic rheumatism, I would deduce that those special terminations of sensory fibres in and near the articular surfaces of joints are the harbingers of moisture. I would even suggest that the existence of authenticated cases of "water divination" by means of rods are extreme cases of susceptibility, occurring, as I believe they do, in ancient rustics.

TREATMENT OF CHLORINE GAS POISONING.

DR. WILLIAM BRAMWELL (Liverpool) writes with reference to the letter from Sir E. A. Schäfer, published last week, to recall a note he published in the JOURNAL of September 18th, 1915, p. 460, in the course of which he said, "The ancient physicians who bled empirically and bled for everything would have bled for gas poisoning, and probably with beneficial effect, except in those cases which had already been bled from a wound." In the same letter he drew attention to Dr. Walter Broadbent's observation to the effect that a big linseed poultice placed over the whole back gave relief, but suggested that india-rubber hot-water bottles to the feet and other surfaces of the body, and particularly to the abdomen, would have a like beneficial effect, and would be cleaner, more convenient, and keep hot longer than the poultice.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postæ restantæ* letters addressed either in initials or numbers.

Notes on Military Orthopaedics.

IV. ON MALUNITED AND UNUNITED FRACTURES.

BY

LIEUTENANT-COLONEL ROBERT JONES, Ch.M.,
F.R.C.S.I. (HON.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

The conditions to which the terms "delayed union" and "non-union" are applied may be difficult to distinguish, because often we find that, even after months, osteogenetic changes leading to consolidation will take place in a fracture considered to be permanently united. If we are to avoid disagreeable experiences, we must recognize that for various reasons, some of which we know and some of which are still unknown, a certain proportion of fractures take longer to unite than others. Some years ago I was called to a distance to operate upon a fractured femur. The accident had occurred three months previously. The length and alignment were good, but the patient had some sugar in the urine, and we decided, instead of operating, to place the limb, free from circular constriction, in a Thomas's bed splint (Fig. 1). Certain other procedures which I advise were not carried out, but in four weeks very firm consolidation had occurred. This case affords an example of a clinical type. There may be several weeks of apparent inactivity in callus formation, and then consolidation occurs quite rapidly. If a practitioner takes care to maintain a good length and accurate alignment, he should look forward cheerfully to a happy issue even if union is delayed. As a rule, this is exactly what he does not do. At the end of the fifth week he begins to feel nervous, he disturbs the bone ends, modifies his methods, and by degree transforms into a permanent disability a condition which merely demanded patience.

FIG. 1.—Thomas's bed splint

Delayed union is most common in the middle of the femur, in the humerus at the junction of the middle and upper third, and in the tibia and fibula at their lower third.

CAUSES OF DELAYED UNION.

In many cases there is an obvious reason for the delayed union. Very often it is not due to malposition; it is, indeed, quite remarkable how often in delayed and ununited fractures the bones are almost automatically opposed. I will not waste time by doing more than mention some of the academic causes assigned—such as tabes, syphilis, and acute diseases. I would prefer to focus attention on the more real and practical conditions which have a direct relation to the method of treatment.

Circular Compression.

An obvious and frequent cause is inefficient reduction, and later on, in dealing with malunion, I will refer to this in greater detail. I will, however, deal first with another cause of delayed union—circular compression of the limb by splint and bandage.

A fundamental principle in the treatment of fractures is to secure and maintain good length and good alignment, and in attaining these ends care should be taken that the

circulation of the limb shall be in no way hampered. The splint used should be so constructed that after the bandage is applied the fingers can be readily introduced between it and the lateral aspects of the limb. In looking back upon the ununited fractures I have seen, I generally recall an attenuated limb and a thick plaster case. When the casing is removed the blanched limb becomes red, and the blanched bone begins to take its fill of blood. It is because plaster generally fails to secure length and adequate blood supply that it is a prolific source of delayed union and ununited fracture. I would not condemn the use of plaster altogether, much as I dislike it, but it should be used with discrimination. It should be fixed in such a way that the limb remains in extension and in good alignment, and that the circulation of the limb is in no way hampered.

Duration of Period of Consolidation.

Textbooks have led us astray in regard to the period required for the consolidation of bone. Fractured adult bones are never firm after four or five weeks, as the books would lead us to infer.

For practical purposes, ignorance of this fact may make no difference in the case of the upper limb, but in the case of the lower limb, where the effect of body weight has to be considered, to underestimate the period of consolidation is to invite disaster.

TREATMENT.

If a case of delayed union is first seen in the seventh or eighth week we need do no more than make quite sure of good alignment, length, and circulation. Nature will do the rest.

Percussion and Damping.

If a long time has elapsed the need for action is more pressing, and we must endeavour to transform the indolent callus into an osteogenetic factory, so that bone may be generated. I know of no better means than that suggested by H. O. Thomas, and named by him "percussion and damping."

Femur.

As an example, I will take non-union of the femur with

shortening probably of two or three inches. Under an anaesthetic the soft fibrous callus is broken down and the fractured ends are turned towards the skin and beaten with a mallet; a pulley is then applied to the limb, and as much length as possible gained. A Thomas knee splint is then adjusted and the extension maintained. Two pieces of indiarubber tubing are tied around the limb,

FIG. 3.—Pulley used in setting and operating upon fracture of tibia and fibula; counter-extension shown.

one three or four inches above the fracture, and the other at an equal distance below. They are kept on, to begin with, for about twenty minutes each day until they can be borne for several hours at a time. They should be kept tied sufficiently tightly to produce considerable swelling and stasis. Usually in two or three weeks callus is thrown out, and the osteoblasts begin actively to produce bone. Local congestion between two indiarubber tubes is much more effective than congestion by one proximal tube. I can recall many cases in which bones that had remained ununited for several months became firmly consolidated after use of this simple device (invented by Thomas and ascribed twenty years later to Bier) for stimulating osteogenesis. The method of applying the indiarubber tubes to produce congestion is shown, applied to the humerus, in Fig. 2.

Tibia and Fibula.

In old ununited fractures of the tibia and fibula complete extension is not so easily attained, and it may be necessary to remove bone. If this be done, the operation should be performed under pulley extension (Fig. 3), or by turning the ends of the bone out of the wound and engaging the fragments in shoe-horn fashion after the method of Lane. If the case be suitable and the surgeon possess the mechanical skill subsequently to keep a good alignment, it is best to avoid the introduction of plates or screws. The bones should be kept in absolutely good apposition, and where it can be easily accomplished they should be wrapped in transplanted fascia which will act as a binding membrane in the same way as periosteum.

FIG. 4.—Bone grafting. A, Lateral bone graft for fracture. B, Lateral bone graft for a case in which bone has been removed.

In another type of case in which the bone is eburnated with feeble callus production, it is well after sawing the ends to crenate the edges with bone nibblers, and to transplant bone from some other part of the body. The sides of the fractured ends should be prepared to receive the transplanted portion, which can be affixed laterally (Fig. 4A), or driven into each end of the medulla. The transplanted bones and the fractured ends are held in position with transplanted fascia wrapped around them.

Figures 5A and 5B illustrate a method of sliding a transplant to bridge over the fracture. Albee's twin saw is used to enable the operator to detach with mathematical correctness a strip of bone partly above and partly below the line of fracture. A chisel is used at either end to complete the detachment. The shorter detached piece (in the figure the lower) is removed and the larger piece is slid down (Fig. 5B.)

Autogenous transplantation of bone is far more effective than transplantation from another patient or from an animal. A bone graft without periosteum is sometimes as effective as one taken with its periosteum. This fact is important, for if bone is removed from some other part of the body subperiosteally, the removed bone is very rapidly replaced by new bone. Where convenient, however, the periosteum should be retained.

Non-union is very apt to occur where a wide gap exists between the bones. In the case of fracture of the tibia of long standing, where the growth of the fibula has progressed, I have operated with success by removing a large lateral slice from the upper end of the fractured tibia, and using it as a bridge to span the gap (Fig. 4B).

Compound Comminuted Fractures: Retention of Fragments.

This leads me to speak of compound comminuted fractures associated with loose pieces of bone. The removal of these pieces is very frequently the cause of non-union.

If loose pieces are felt, provided the wound is not suppurating, they should be scrupulously saved; the pieces, if quite loose, should be taken out of the wound and laid in alcohol, and then carefully replaced in position or round the site of fracture. In such cases I refrain from introducing any foreign bodies, such as nails, plates, or wires. If a drain be used at all, it should be for forty-eight hours only.

Weak Union: Exuberant Callus.

Malunion of the femur of six or seven weeks' duration can almost always be corrected by powerful manipulation. The same is true of all the long bones. At my clinic every week I am accustomed, by wrench or hand, to correct malunited fractures of several weeks' standing. The method is especially applicable to a Colles's or a Pott's fracture.

Weak union can be diagnosed almost with certainty even when ordinary manipulation fails to detect it. It is suggested by tenderness on pressure over the site of the old fracture, and confirmed by the additional sign of exuberant callus exudation. A malunited fracture of some months' duration, if accompanied by these two signs, can usually be corrected by forcible manipulation. This is a very important clinical fact to remember from the point of view of immediate or gradual correction.

Exuberant callus is sometimes so abundant as to be mistaken for malignant disease, and I have met with many instances in which the patient has narrowly escaped amputation. This error is more likely to occur in the femur than in any other of the long bones, especially when the force applied to produce it has been so slight as to suggest that the fracture was spontaneous.

MALUNION.

Malunion of a fracture can always be prevented, and should raise a strong presumption of inefficient treatment. Our duty, therefore, is to examine the cause of malunion, and to arm ourselves with a knowledge of the weak points in our method of treatment.

The causes of malunion may be found (1) in errors in the initial treatment or setting of the fracture, (2) in errors in the method of maintaining the fracture in position, or (3) in errors of after-treatment.

I. INEFFICIENT REDUCTION OF THE FRACTURE.

Malunion of a fractured bone is due to this cause more often than is commonly supposed. Sometimes it is due to want of knowledge, but more often to want of experience and confidence.

It is necessary, of course, to have a clear knowledge of the anatomical proportions of the limb and of the mechanics of its action; but it is still more important to know the

FIG. 5.—Bone grafting. A, Diagram showing incisions through tibia by twin saw and chisel, detaching a strip above and below the fracture. B, Second stage of operation. The lower fragment has been removed, and the upper has been pushed down so as to bridge the fracture (Albee).

FIG. 6.—End-to-end apposition of fractured femur. A, End-to-end apposition and perfect alignment; B, imperfect apposition but with good alignment; C, end-to-end apposition with faulty alignment.

nature of the impairment of function likely to occur after any particular fracture, so as to be ready to take means to anticipate and to prevent it.

Common causes of inefficient reduction are—

(a) Insufficient extension of the limb in fractures of long bones—such as the femur or humerus—so that the overriding of the fragments is not completely corrected.

(b) In Pott's fracture there is always an associated dislocation of the ankle outwards and backwards. If the backward dislocation is not fully corrected there is pain over the front of the ankle when the patient walks, and, in addition, inability to dorsiflex the ankle, which causes a serious impairment of function.

(c) In Colles's fracture the backward displacement of the lower fragment is very serious, and is not always corrected by the orthodox traditional "hand-shaking" method of reduction. The lower fragment carries with it the articular surface for the head of the ulna, and if this is out of line, the upper and lower articulations between the radius and ulna are thrown "out of truth" and the radius will not rotate properly. This leads to impairment of pronation and

of long bones lead to shortening. In fracture of the neck of the femur it modifies the angle between the neck and the shaft and so causes the flexion of the joint, with the result that body weight is not transmitted in the normal line. In consequence of this, crippling changes of an osteo-arthritic character subsequently occur in the joint. Faulty alignment of the bones may arise from inefficient fixation, even in a case in which the fracture was originally fully reduced and the bones brought into correct alignment (Fig. 6). The result is that the true line of the shaft of the bone is not maintained, and the joint at one end of the bone is thrown out of its proper relation to the joint at the other; in consequence, muscles do not act in their correct line, and the usefulness of the limb is impaired. Further, in the lower limb the line of transmission of body weight is altered, and this throws an improper strain on joints and ligaments, resulting in changes in the joints, in flat-foot, and in other disabling deformities. For instance, in fracture of the tibia and fibula a little shortening of the limb does not seriously impair its strength if the alignment is good. A slight bow-leg even is not serious (Fig. 7 A), for slight bow-leg is a harmless type. Many muscular and powerful men are, indeed, slightly bow-legged, but in a valgoid deformity the weight of the body is carried too far to the inner side of the foot, and this throws too much weight on the arch, and the result is a flat and everted foot (Fig. 7 B).

Any valgus deformity at the knee, in the leg, or at the ankle is a weakening deformity, and greatly reduces the usefulness of the limb. It is a good fault, therefore, to err on the side of producing a slight bow-leg, with its varoid accompaniment, if there is to be any error at all. In cases of malunion, when the callus is still tender, it is generally not difficult to readjust the limb by manipulation without having to perform an open operation. In the case of the femur, this can usually be done two, or even three, months after the original fracture. As a rule, the worse the position of the bones the longer will the callus take to consolidate.

The next point to which I would draw attention is that callus may yield in such a way as to throw the bone out of proper alignment. A good example of this is frequently afforded by cases of Pott's fracture which have been correctly reduced, and six weeks later are in good position and united. A month after this, however, the patient may complain of some pain at the site of the fracture, and also of symptoms of flat-foot.

Here the counter pressure of the ground on the foot forces the astragalus against the external malleolus, and so produces a lever action, straining the callus. To avoid this, every case of Pott's fracture should be set to walk with the inner side of the heel raised to keep the foot inverted, and if the patient is a heavy subject an outside brace also should be worn (Fig. 8 A and B). It is disconcerting and puzzling to see a perfectly good functional result replaced by a bad one; to avoid disappointment of this kind it is advisable, particularly in fractures of the lower limb, to apply some sort of guard to prevent straining of the callus.

Here the counter pressure of the ground on the foot forces the astragalus against the external malleolus, and so produces a lever action, straining the callus. To avoid this, every case of Pott's fracture should be set to walk with the inner side of the heel raised to keep the foot inverted, and if the patient is a heavy subject an outside brace also should be worn (Fig. 8 A and B). It is disconcerting and puzzling to see a perfectly good functional result replaced by a bad one; to avoid disappointment of this kind it is advisable, particularly in fractures of the lower limb, to apply some sort of guard to prevent straining of the callus.

THE FUNCTIONAL IMPAIRMENT ASSOCIATED WITH VARIOUS FRACTURES.

Before discussing the treatment to be adopted in particular cases, it is well to recognize the forms of impairment of functions commonly associated with each fracture.

FIG. 7.—Diagrams to illustrate effects of malunion of tibia. A, Malunited fracture of tibia producing bow-leg and throwing body weight on to outer side of foot. B, Malunited fracture of tibia in such a position that the weight of the body is carried to the inner side of the foot, producing flat-foot.

supination, and consequent very serious interference with function.

These are merely instances of how a want of sufficient determination in reducing the initial deformity may play an important part in causing subsequent loss of function. I have referred to them because they occur in common fractures, with the treatment of which everybody ought to be familiar, yet I see a large number of cases of serious impairment of function really due to these causes.

II. FIXATION AFTER SETTING OF FRACTURE.

If the fixation of the limb after the fracture has been reduced is in-

FIG. 8.—Boot and iron for use after Pott's fracture. A, Showing the boot with crooked and elongated heel and the outside iron; B, the same applied.

efficient so that material amount of movement can take place between the fragments, then every such movement causes pain, and produces a reflex contraction of the muscles. This reflex spasm may very readily cause overriding of the fragments, and in the case of the shafts

FIG. 9.—Position for fractures about elbow in the adult. The elbow is even more flexed in children.

FIG. 10.—To show the complete supination and extension of the arm necessary in fractures of radius and ulna.

Humerus.

Fractures of the humerus near the shoulder-joint (that is, those of the surgical neck and above the insertion of the deltoid) are commonly associated with inability to abduct the limb fully. The reason is that the upper fragment is often tilted outwards, and end-to-end union does not take place. In order to avoid this, the surgeon's object when setting the fracture should be to bring the fragments end to end if possible. He should pull the arm at right angles to the trunk, or even straight upwards until all overriding is completely overcome, and should then endeavour to engage the end of the lower fragment on the broken end of the upper fragment. By pressing the two together he can at once tell if they are engaged or are sliding past each other. If they are engaged, the arm can be gently brought down to the side and secured to the trunk by bandages. Once the fragments are engaged they are not likely to become disengaged again.

FIG. 11.—Dorsiflexion of wrist for fracture of carpus.

Elbow-joint.

In fractures about the elbow-joint, with the single exception of fracture of the olecranon process, the usual disability is limitation of flexion.

The limb should therefore be extended to push away any fragment likely to obstruct extension afterwards. The forearm should be supinated to make sure of clearing a right of way in that direction, and then the elbow should be fully flexed and bandaged (Fig. 9), care being taken not to produce tight circular constriction of the limb in any part. In this way we may make sure that there shall be no callus exudate in the bend of the elbow, and at the same time the tendon of the triceps acts as a posterior splint.

When a stiff elbow, after an injury, has to be dealt with, the same manoeuvres are gone through so as to force the recently formed callus out of the way until full flexion is secured. Usually this can be done on one occasion, but in some cases it may be necessary to flex the joint in two or three stages.

Radius and Ulna.

In fractures of the bones of the forearm the disability most to be feared is obstruction to supination; pronation is usually good. Therefore, in setting the fracture, or when breaking down callus and resetting the fracture, the surgeon should extend the forearm and supinate fully in order to make sure of a clear right of way for supination, and then set the fracture, taking great care that the ulna is perfectly straight, and that there is no lateral pressure anywhere on the shaft of the radius (Fig. 10). It must, however, be remembered that the radius is a curved bone

which rotates on the ulna like the handle of a bucket; if the arched shape of the radius is destroyed the joints at its ends will be out of their true line, and impairment of function will be the result.

Carpus.

Fractures of the carpus often result in a stiff wrist in a flexed position. Every schoolboy knows that the grasp of the hand is weakest when the wrist is flexed. Therefore, in every case of fracture or injury of the carpus, the wrist should be put up in a hyper-extended position (Fig. 11).

If the wrist has been allowed to get stiff in a flexed position, it should be dorsiflexed under an anaesthetic and fixed in that position. In rare instances a fragment of the scaphoid is displaced on to the dorsum and blocks extension; if this has occurred, it may be necessary to remove the fragment before the wrist can be hyper-extended.

Ankle-joint.

When we turn to fractures near the ankle-joint we find that many patients complain of both pain and stiffness

which lasts for months or years. A study of the causes brings to light two principal factors responsible for loss of function here. Eversion of the foot, for instance, is fairly well recognized as one of them (Fig. 12). If the patient is allowed to recover with the ankle in a valgus position, the body weight when he stands will fall too far to the inner side of the foot, and at once all the factors which make for the production of flat-foot are produced. It is, however, not sufficiently well recognized that these conditions may be at work in an ankle which has every appearance of being in good position when the patient is discharged from hospital. Straining of young callus by body weight is very common in fractures around the ankle-joint, owing to the patient being allowed to walk on the unprotected joint too early. I therefore always turn these patients out with a "crooked" heel and often with an outside brace as well, to ensure that the body weight shall fall on the outer side of the foot (Fig. 8A, 8B). The natural corollary of this is that if body weight will produce a valgus deformity by straining the callus, it will also correct it if we "crook" the boot well, and therefore when the callus is already strained in the valgus direction, and the patient comes with a stiff painful ankle and foot, all we need do in many of the milder cases is to crook the boot well on the inner side, and let the patient "walk out" his deformity. In older and more severe cases it is from the first necessary or advisable to wrench the foot into an inverted position under an anaesthetic, and then let him walk with his heel well crooked; this is made easier by the application of an outside brace (Fig. 8). If this after-treatment is not persisted in for some weeks the condition will most likely recur.

The second great disability, after injuries about the ankle-joint, is inability to dorsiflex the ankle. The patient, when walking, cannot get forward on to the toes and fore part of the toes without pain across the front of the ankle.

This is a very difficult condition to correct once the deformity has been allowed to become established. The proper thing is to prevent it when the injury is recent; to make sure of this the surgeon should dorsiflex the foot and so satisfy himself that he has commanded a complete and clear right of way for this movement in the future.

Both these disabilities are well illustrated by cases of Pott's fracture; this injury essentially consists of a fracture of the fibula about three or four inches above the external malleolus with a dislocation of the ankle outwards and backwards (Fig. 13). There may be minor complications, such as fracture of the tip of the internal malleolus or the less well recognized fracture of the edge of the articular surface of the tibia. These, however, do not alter the general nature of the disability.

The method of reduction I adopt is the following: The knee is flexed to relax the calf muscles. If these muscles give trouble, tenotomy of the Achilles tendon will put them out of action, but this is only necessary in exceptional cases, and strength returns but slowly after this apparently harmless operation. Grasping the foot by the heel in one hand and the dorsum in the other, the foot is pulled and everted to make sure of thoroughly disentangling the fractured ends. While still pulling, the foot is fully inverted and the ankle dorsiflexed. If the ankle cannot be dorsiflexed fully, it means that there is a definite posterior dislocation or that the anterior edge of the tibia is fractured. It is necessary then to push the tibia back and bring the foot well forward until the ankle can be well dorsiflexed. The foot is then fixed in splints in the fully inverted

FIG. 13.—Malunited Pott's fracture, showing dislocation backwards of the foot.

FIG. 12.—Malunited Pott's fracture, showing eversion of foot.

FIG. 14.—Operation for malunited Pott's fracture; wedge from tibia and osteotomy of fibula.

position and dorsiflexed a little beyond the right angle. If the surgeon maintains it in this position, he may wait with confidence for a good result. If he is content with a less thorough reposition, he is in great danger of getting a result with some stiffness, pain, or limitation of movement, which will seriously interfere with comfort in walking. Since the days of Percival Pott many splints have been devised. The shape and style of the splint does not matter a jot. The important element is the surgeon. If he knows his work, he will fix the foot in the position described and will be rewarded by a good result.

As we have seen, malunion and consequent functional disability depend on two factors: (a) eversion, (b) diminished dorsiflexion.

(a) Eversion often calls for operation. In comparatively simple cases all that is needed is to pass a chisel through the internal malleolus, and also through the site of the old fibular fracture. The foot should then be forcibly inverted, and treatment continued to maintain the inversion. In the more severe type of case an open operation is advisable. A wedge of bone is removed from the lower end and inner side of the tibia (Fig. 14). The wedge should only go a distance of four-fifths through the bone. An osteotomy of the fibula is next performed. The wounds are closed, and not dressed for twelve or fourteen days. The stitches are then removed, and, under gas, the limb is fractured by forcible inversion. This two stage operation eliminates the anxiety which must attend the treatment of a compound fracture, and this is an important matter when powerful manipulation is necessary. For many reasons, however, it may be advisable to complete the reduction at the time of operation.

(b) Dorsiflexion of the ankle may be blocked by callus exudate the result of fracture of the anterior articular edge of the tibia. Complete dorsiflexion of the ankle at the time of accident would save the patient from this deformity, for the fragment of bone would in this way be pushed to one side, but if this has not been done, and at a later date we find that dorsiflexion is prevented, an incision should be made and the offending prominence chiselled away. The space left by the removal of bone should be packed with fat removed from any convenient part. This prevents the new callus exudate from giving

FIG. 15.—Fracture of neck of femur. A, Fractured neck, showing position in abduction. B, Fractured neck of femur correctly reduced in abduction.

rise to trouble. In all operations where bone is removed and pseudarthrosis is desired I find the generous employment of fat most helpful, and in order to reduce the callus exudation the exposed cancellous bone should be lightly hammered.

Tibia.

In fracture of the tibia faulty alignment may be brought about by posterior bowing; the weight of the body may

be thrown so far back that it passes at some distance behind the ankle, as shown in Fig. 15.

Fractures of the Femur.

Fractures of the neck of the femur, and all fractures about the small trochanter, should be treated in the

FIG. 17.—Fracture of upper third of femur. A, Adduction deformity. B, Abduction faulty, as the upper fragment does not participate.

abducted position to prevent deformity of the coxa vara type (Fig. 16 A and B). Stiffness of the hip associated with limitation of abduction, often accompanied by "osteo-arthritis" changes in the hip-joint, is the sequel of malunion in this region. To prevent this it is necessary to secure abduction and to maintain extension in the abducted position. If the fracture is of some weeks' standing and the area is still tender, the callus is certainly not consolidated; forcible abduction and extension in an abduction frame and rigid fixation in this position will then be followed by adaptation of the callus to the corrected position.

Fractures of the shaft of the femur, especially in the middle third, are frequently followed by gross forms of malunion, which will excellently serve to illustrate malunion in long bones.

The faults commonly found are:

1. *Shortening or overriding*, due to the fact that (a) reduction has been incomplete, the surgeon not having pulled until the fractured limb was at least as long as its fellow; (b) the method of fixation and extension used has been inefficient, and the muscles have caused overriding after the fracture was set; (c) the body weight has caused yielding of the callus after the patient has begun to walk.

2. *Angular deformity or erroneous alignment* is the result of inefficient methods of fixation, and more particularly of inefficient extension in the line of the limb. Erroneous alignment throws all the muscles of the part out of line, and, what is more important, puts the joints above and below out of their correct relations. A common fault in fractures at the junction of the lower and middle third is a posterior sagging (Fig. 18), which is best seen when the patient begins to walk. The body weight is thus thrown on the posterior part of the capsule. The deformity resembles a genu recurvatum.

3. *Rotation deformity* is far too common, and can only be the result of careless and inefficient treatment.

Diagnosis.

In a case of malunion of the shaft of the femur in which one or more of these elements are present the whole region

FIG. 18.—Diagram to illustrate posterior sagging in malunited fracture of femur in the middle third.

of the fracture is tender, and is also the seat of pain for weeks and months after consolidation ought to be complete. This means that consolidation is far from complete, and that the callus is the seat of active change. Nature, in fact, is struggling with the problem of buttressing up the malunited fragments so that they can meet the forces which are acting in them, hence the exuberant production of callus, which is attended by pain and tenderness.

Treatment.

In such cases it is not difficult to break down the callus by manipulation. Extension with block pulley and suitable tackle will then stretch the muscles and reduce the over-riding by $2\frac{1}{2}$ inches on a single occasion (Fig. 3). Rotation deformity is, of course, corrected at the same time.

If open operation is employed, the simplest form of osteotomy is an oblique one through the callus between the original fragments of the shaft. Once these are cut through the greatest part of the remaining difficulty is in fully restoring the length of the limb by extension. The big muscles of the thigh can only be fully overpowered by the use of block pulley and tackle (Fig. 3). When this has been accomplished the leg is fixed in a Thomas's knee splint, the tuber ischii rests on the padded ring, the extension straps are secured to the bottom of the splint. We are then sure that, whatever happens, the muscles cannot contract and cause farther overriding. The only thing the muscles can do is to give up the struggle, and, as a matter of experience, this is what always happens.

FIG. 19.—Fracture of upper third of femur. Diagram to illustrate osteotomy to correct common deformity.

FIG. 20.—Fracture of upper third of femur. Diagram showing removal of wedge of bone to correct adduction.

The surgeon finds on his next visit that he can get perhaps another half inch of lengthening by further extension on the straps. Further, in a Thomas's knee splint good general alignment of the limb can easily be secured—in fact, is obtained almost automatically. The only points to which the surgeon has really to attend are the position of the foot—to see that there is no outward rotation—and to keep up firm extension.

Locally, splints are applied to control lateral movement. In the first instance this is not difficult. When resetting a malunited fracture it is not so easy, for the callus already formed gets in the way.

In these malunited fractures of the femur of some weeks' standing with considerable overlapping, after refracturing the bone by force the pulleys should always be applied and a great effort made to secure both length and alignment. To render this less difficult, it may be wise to move the fractured ends freely in all directions to disturb and disengage the fibrous and bony exudate. The extension by pulley should be maintained for several minutes to lessen the resiliency of structure and to reduce the chance of telescoping. The limb is then maintained in extension by a Thomas's splint, and on two or three subsequent occasions the pulleys are applied. By these simple means overlapping of three or four inches can be overcome, and an open operation is avoided. The "damming" method already described is applied to assist osteogenesis, aided when necessary by percussion.

Whatever operation may subsequently be needed, I cannot too strongly urge the necessity of preliminary pulley traction in order to secure a better length, and in this way prevent the sacrifice of bone.

In cases in which union in the vicious position is so complete and firm as to render operative procedures neces-

sary, the procedure to be followed is influenced by the special type of union present. If it is a mere case of faulty alignment, with fair apposition, a small puncture and an osteotomy saw will do what is desired (Fig. 19). An x-ray photograph should be taken, and the section made through the angle. The

case is then treated as one of simple fracture. If there is overlapping of the fragments, with no excessive callus, the saw is introduced between the fragments and

FIG. 21.—Author's osteotomy saw with protected end.

the lateral fixation undone. Pulley extension will then diminish or obliterate the shortening, and the subsequent treatment will maintain both length and alignment. In other fractures higher up, with great thickening and lateral deflexion, a wedge is removed from the convex side of the bent bone, and a fracture at the point preferred may be produced some days later (Fig. 20). Extension and abduction of the limb should then be secured. In rarer instances, when unusual deformity and overlapping have occurred, it may be necessary to explore the fracture by a free exposure, to separate the fragments, to remove bone, and to plate.

CONCLUSION.

It may appear that in this paper I have dealt more with the treatment of fractures than with the treatment of malunited fractures, but a moment's reflection will satisfy us that there is only one problem before us—the restoration of function. Operation or manipulation to free the ends of the bones when union has occurred in a faulty position is only a preliminary step. In short, a malunited fracture cannot be cured by operation—all the operation can do is to reconstitute the fracture or make another fracture similar to the first.

If after this the subsequent treatment is not better than the treatment adopted in the first instance, an improvement in the result is not to be expected. This is probably why the statistics of late operations to correct malunion are often disappointing. The surgeon must not merely reduce the fracture, but must maintain the corrected alignment until consolidation of the bone is secured.

The fundamental principles applicable to simple fractures hold good in the case of compound fractures. The difficulties in carrying them out are obviously materially increased. Once, however, serious complications are past there will be ample time and opportunity to correct faulty alignment and to restore the best possible function to the fractured limb.

The fractures met with as a result of gunshot wounds are usually very serious, and I have witnessed with pride the splendid efforts made by the young surgeons in France to save these mangled limbs. Sometimes we hear criticisms at home, not always kindly, sometimes very unjust, because amputations are performed without flaps, and limbs still suppurating are not in the best position. If the whole truth were known, these mangled limbs and flapless amputations often represent surgical triumphs where every art and device has been concentrated upon the salvation of life and limb.

SURGEON-GENERAL GORGAS, with a party of medical men, is making an extended tour of South America to study methods of eradicating yellow fever. The expedition will visit Ecuador, Brazil, Colombia, and Venezuela. It is expected that the work will occupy four months.

In the *Deutsche medizinische Wochenschrift* for December 2nd, 1915, an account is given of negotiations conducted between the society of *Frauenbildung-Frauenstudium* of Mannheim on the one hand and the Medical Department of the German War Office on the other. To an inquiry why lady doctors were no longer required for military hospitals, the War Office replied that the lady doctors were discharged principally for general military disciplinary reasons, and that it was not to be assumed that this reflected on the medical capacity of the lady doctors. It was, however, the opinion of the War Office that the lady doctors were required rather for the civilian population (particularly for women and children) than for the army, which was already adequately supplied with medical aid.

OBSERVATIONS ON SPIROCHAETA EURYGYRATA, AS FOUND IN HUMAN FAECES.

By H. B. FANTHAM, M.A.CANTAB., D.Sc.LOND.,

LIVERPOOL SCHOOL OF TROPICAL MEDICINE; HONORARY
PARASITOLOGIST WESTERN COMMAND.

Introduction.

RECENTLY attention has been directed to the Protozoa and allied Protista occurring in the faeces of soldiers who had contracted various forms of dysentery or diarrhoea in Gallipoli or Flanders. A few papers recording the results of such observations have been published, but no mention has been made, so far as I am aware, of the occurrence of spirochaetes in the faeces of such patients, except by Fantham and Porter in 1915. Similar spirochaetes may occur in the motions of apparently healthy persons. Frequently the stools of dysenteric patients found to contain the organisms were fluid and rather foul-smelling. Apparently the pathogenicity of such spirochaetes is slight, but they seem able to flourish and multiply in dysenteric intestines.

Material and Methods.

The material, as already indicated, was chiefly obtained from the stools of dysenteric patients during 1915-16. The stools of a few normal persons were also examined. When dealing with large numbers of stools in a somewhat limited time, as has been necessary on many occasions, the organisms were observed in fresh preparations, between coverslip and slide, with the aid of $\frac{1}{8}$ in. or $\frac{1}{4}$ in. objective and Huyghenian ocular 3. Twenty-three cases of single infection with spirochaetes were detected by this means alone in three months. However, the spirochaetes are seen to be more numerous in a preparation, and to occur more frequently in stools, if dark-ground illumination is used. Also, if stained smears of stools are made, many more infections will be found, perhaps even as high as 50 per cent. of the cases examined.

The organisms may be fixed wet in osmic vapour, hardened in absolute alcohol, and stained with gentian violet, iron-haematein, haematoxylin, thionin, and the various modifications of the Romanowsky stain. Bouin's fluid and corrosive acetic alcohol may also be used as fixatives, while dry smears may quite well be used for rapid diagnosis.

Movements.

The spirochaetes observed in faeces move quickly, and their bodies exhibit great flexibility. As I have previously pointed out (1907, 1908), the movements may be divided into two components—an undulatory flexion of the body, mainly for progression, and a corkscrew or helicoid movement of the body as a whole, due to its coiling. The number of waves along the body of a spirochaete varies according to the rate of progression of the organism, and is an index of its rate of motion, being also slightly influenced by its thickness. The coil of the helix of a rapidly moving spirochaete is much closer than that of a slowly moving organism. In other words, the body of a rapidly moving spirochaete is thrown into many small waves, while slowly moving forms are thrown into fewer, larger waves, as I have shown in my work on *S. bronchialis*. If a single living specimen be watched for a sufficiently long time under the microscope to allow of its changing its rate of motion, the change in the character of the coils can be observed. Reversal of direction of movement is common. Either end of a spirochaete can be forwardly directed, and the organism can easily return on its path. Corkscrew, boring movements also have been observed, and Catherine-wheel-like motions have been seen.

Agglomeration of the gut spirochaetes is common, tufts or tangles being produced. In my experience, such agglomerations or tomenta are more common in fluid stools than in semi-formed ones or those of normal consistency. The individual members of a cluster can easily separate from or rejoin the group.

On some occasions when shed epithelial cells from the intestinal wall have been present, spirochaetes have been seen to penetrate the cells. After a relatively short time they usually became quiescent there, and sometimes produced their resting coccoid bodies. Occasionally the spirochaetes might be seen to emerge again from the cell.

While usually the movements of the spirochaetes are very graceful and are undulatory and corkscrew in character, very rarely jerky or boomerang movements have been observed. These latter are perhaps more obvious in some of the shorter spirochaetes.

Morphology.

The spirochaetes of faeces are best termed *S. eurygyrata*, as will be shown in a subsequent section. They have markedly flexible, sinuous bodies, and, when observed in numbers, present morphological variation. The bodies of the organisms show a series of curves or waves, the exact number of which depends chiefly on the rate of motion prevailing at the time the spirochaetes are fixed or observed. The number of curves or waves may be as small as two or as great as nine. Bowed and coiled forms may also be seen. The ends of the organism vary somewhat, according to the stage of growth or the recentness of division. Usually they are tapering. (See text figure.) Some may be rather more rounded, while others have quite pointed ends. A few spirochaetes with one end more pointed than the other have also been seen, the appearance resulting from the extending attenuation at a recent division. Similar morphological variation in *S. balbianii* was described and explained by me in 1909. Internally, a diffuse nucleus consisting of chromatin rodlets or granules can be observed in well-stained specimens from stools, or in living forms examined by the aid of the paraboloid condenser. In the latter case, the chromatin granules appear as minute refractile spots. However, it is not always easy to see the granules.

The cytoplasm of the spirochaetes is almost homogeneous and is non-vacuolated. The presence of the chromatin granules or rodlets at intervals down the body gives rise in clear specimens to the alveolar or chambered appearance mentioned by some workers in connexion with the larger spirochaetes found in molluscs.

In some spirochaetes the periplast is seen to be laterally extended in the form of a very slight sinuous membrane or crest, which is only observed with great difficulty, as it is often contracted against the body.

By measuring a number of spirochaetes obtained from various patients on different days, the variation in length was found to be from 3μ to 15μ , and the breadth was about 0.25μ or less. The breadth, however, is not easily determined, but some forms are clearly stouter than others. Multiplication by binary fission has been observed in the living organisms and forms undergoing similar division have been seen in stained preparations.

The formation of coccoid bodies or granules in the gut spirochaetes has been studied in fresh preparations by both ordinary illumination and sometimes by the use of the paraboloid condenser. The cytoplasm concentrates around the chromatin rodlets and the concentrations gradually become oval. The coccoid bodies thus formed are set at liberty, either by ruptures in or disintegration of the parental sheath. The elongation of coccoid bodies, their assumption of the spirochaetiform facies and their emergence from groups of such bodies have all been observed in life.

The spirochaetes as such may disappear from the stools of a patient and then after some days reappear again, and thus there is variation in numbers from day to day. The more fluid the stool the greater is the number of spirochaetes present as a rule. During the period when the spirochaetes as such are absent from the stools, it is probable that they have produced granules or coccoid bodies. Owing to the large amount of finely divided debris present in the intestinal contents, it is not yet considered practicable to differentiate spirochaetal granules from other minute particles in stools. In my opinion, granules cannot be considered, at present, to be definitely spirochaetal in origin unless their formation from and subsequent elongation and development into spirochaetes have been observed in the living organisms.

A large number of drawings of the spirochaetes found in human stools have been prepared, and it is hoped that

Spirochaeta eurygyrata,
morphological variation.
 $\times 1,400$.

it will be possible to publish them later, when the morphological variation exhibited by these organisms will be more fully shown than is possible in the text figure.

Earlier Observations.

There are a few vague references in the literature to spirochaetes, or spirilla, as they were often called, in human faeces. Thus, H. Kowalski (1893, 1894) recorded the presence of spirilla in cholera motions examined by him. Apparently no illustrations or dimensions of the organisms were published, and at first they were not named. The number of curves, "about one, two, or three, seldom four, five, or many," is noted. Kowalski's first observations, made on eleven cases, are recorded in an incomplete form in the report of a meeting of a medical society in Vienna in December, 1893. During the discussion thereon Paltauf stated that Escherich in 1884 had seen spirochaetes in normal human faeces. Escherich himself in 1894 referred to his previous work in 1884-86, and stated that he had found spirilla in diarrhoeic stools of babies and adults and in cats. He compared them with dental spirochaetes, but found them to be shorter. Abel (1894) and Aufrecht (1894) also recorded the finding of spirochaetes in the faeces of a few cholera patients, the latter worker comparing them with blood spirochaetes. Rechtsamer (1894) mentioned the finding of spirilla in the dejecta of cholera patients in Caucasia.

Lustig and de Giaksa, writing in 1894, refer to their earlier work in 1886 on the stools of four cholera cases in Trieste, in which the occurrence of spirilla was noted. In their earlier paper (1886) these authors give drawings of a few spirilla, but neither state the dimensions of the organisms nor name them. On examining their illustrations I find that the spirilla measure up to 13μ . As a result of a discussion of the work of Lustig and de Giaksa, Kowalski (1894) named his organisms *Spirillum hachaisae* or *S. hachaisicum*. However, as no dimensions and no detailed differential characters were given, either by Kowalski or the other earlier workers—most of whom called the organisms spirilla or spirochaetes indifferently, though the parasites are not stated to have had flagella, characteristic of spirilla—it is very doubtful whether Kowalski's names are valid.

"Spirillar" or spirochaetal dysentery has been briefly recorded by Le Dantec (1903). The patient, who came under observation in the neighbourhood of Bordeaux, had been known to the author for some time, and had been at Tonkin eighteen months before, when in the French Colonial Medical Service. It was stated that the patient developed dysentery in Bordeaux. Spirochaetes were found to be abundant in the mucus of the stools. Some of the organisms showed three curves, and were 6μ to 14μ long. Coiled-up and bowed forms were also seen. Some spirochaetes were observed to enter and emerge from intestinal cells.

Werner (1909) found spirochaetes in his own stools while apparently in good health, though he had suffered from diarrhoea when in German South-West Africa in 1905. A few other cases are also mentioned by him, among them the occurrence of spirochaetes in a case of sprue. Werner separated two species of spirochaetes, which he considered to be distinct. He named these *Spirochaeta eurygyrata*, "a wide wound form," varying in length from 4.6μ to 7.3μ ; and *S. stenogyrata*, "a narrow wound form," varying in length from 3.5μ to 6.1μ . Only six indistinct microphotographs illustrate the paper, and they hardly justify Werner's statements.

Werner differentiated partly on the character of the "windings." As I (1915) have previously pointed out, the number of windings or curves is not of specific value, but is chiefly an indication of the rate of movement. Further, the processes of growth and division will easily explain the so-called differences in morphology and size between Werner's species. Morphological and biological variations appear to have been overlooked in the desire for the creation of new species.

In 1914 J. G. and D. Thomson recorded the presence of spirochaetes in the stools of healthy individuals, of patients suffering from rheumatoid arthritis, of a case of profound anaemia, and of a case of amoebic dysentery. They also found what they considered to be Treponemata in human stools. Macfie (1915) found spirochaetes in the stools of a monkey suffering from amoebic dysentery in West Africa, and in those of diarrhoeic patients in Accra.

Nomenclature.

From the foregoing remarks it will be seen that the nomenclature of the spirochaetes found in human stools is in a very confused state, owing to lack of precision and detail in the incomplete descriptions published. As already indicated, the species *S. hachaisae* is insufficiently defined, and its name appears to be invalid.

It is probable that the earlier authors, and, indeed, all those mentioned in this paper, were dealing with the same spirochaete, which exhibited morphological variation due to the processes of growth and division. The first name proposed by Werner—namely, *S. eurygyrata*—will then be valid. It is therefore necessary to amend the definition of the organism as follows: *Spirochaeta eurygyrata* has tapering ends, measures up to 15μ long, and is about 0.25μ broad. It contains a diffuse nucleus consisting of chromatinic granules. The number of coils or waves is variable, depending on the rate of movement and thickness of the organism.

Conclusions.

Spirochaeta eurygyrata, Werner emend. Fantham, may occur in the stools of dysenteric and apparently healthy persons. The organism, which has pointed ends, measures from 3μ to 15μ in length by about 0.25μ in breadth.

The so-called spirilla, mentioned by some of the earlier workers as occurring occasionally in cholera motions, are included under the name *Spirochaeta eurygyrata*.

The number of coils in a spirochaete is not a specific character but is variable, and is primarily an index of its rate of motion, being also partly dependent on the thickness of the organism.

PERFORATING AND PENETRATING WOUNDS OF THE CHEST WITH SEVERE HAEMORRHAGE:

A SUGGESTION FOR TREATMENT.

BY

A. DON, F.R.C.S., MAJOR R.A.M.C.(T.).

I HAVE been impressed with the impotency of treatment for severe haemorrhage in these cases, and have recently had an opportunity of trying a method which I have not seen advocated elsewhere, and I offer it for consideration and trial by surgeons near the front. The severer cases

almost all die of haemorrhage within the first few hours, and so far there has been little success in attempts to check this mortality. The movements of respiration with its suction force, combined with the elasticity of the lung itself, tend rather to a continuance of haemorrhage than to natural arrest. Plugging the wounds in the chest wall, unless fortunately the bleeding vessel is an intercostal, and is by chance compressed against a rib, seems to do more harm than good, to hasten rather than retard the end. The method is extensively used, but if it is to arrest the bleeding from the lung itself, which is oftenest the cause of death, it must allow complete rest to the lung by collapse, and before this can take place the pleural cavity has to be full of blood. Slow collapse of the lung would not be nearly so effective in arresting severe haemorrhage as sudden collapse, and a pleural cavity filled with blood spells a bloodless and often moribund patient.

If one considers the mechanism and physics of respiration one finds that with each inspiration there is a lifting of the chest wall and depression of the diaphragm, which tends to produce a vacuum in the pleural space by a sucker-like effect. A wound of either pleura will have this suction applied to it, and every child knows how little effort is required to suck blood from a pinprick in the finger. The suction power of the mouth is feeble compared with that of the chest in the pleural space owing to the intervening column of air in the lungs, and the elastic lungs themselves.

The suction in the pleural cavity is exerted strongly from the commencement of the act of inspiration to that of expiration, and more feebly, though of the same kind, during the whole expiration. A bleeding point thus has a suction pump applied to its open rent, and a clot is prevented from forming, for even at the end of expiration the lung occupies a much greater space than it would occupy if the chest wall had an opening in it and the lung were completely collapsed. The same process of suction takes place also throughout the lung tissue, and there is added the elasticity of the lung itself, which pulls apart and keeps open any rent. Unless a very large vessel be torn there is not apt to be so much bleeding into the trachea as into the pleural cavity, though it may equally be continuous for days, for there is not so great suction force to the trachea side, and it is not so uniformly exerted during the whole respiratory act. The suction is positive during inspiration, the air pressure being negative and almost equal during expiration. But there is the cough to consider.

To overcome both the suction and the elastic forces and to allow the lung a complete rest till haemorrhage has been arrested, I thought of making a temporary opening into the pleural cavity, allowing the lung to contract quickly, and, if necessary, washing out the blood clot. In most of the cases of chest wounds, especially from shells, the haemothorax has later (reports from base hospitals) become septic and death from empyema has supervened. This infection of the blood clot is almost certain to happen, for it may be, and usually is, infected by the missile, or it may be, and sometimes is, infected from a septic pneumonia arising in the injured lung. There is then the difficulty of diagnosing this empyema. Fluid and dullness are already present from the haemothorax, and the rise of temperature may not be sudden, and may be due to the septic pneumonia. One could, of course, put in a needle daily, but the risk of infection from repeated punctures is as great as from the single stab of operation. Besides—and this is not unimportant—one hesitates to disturb and pain a serious chest case daily. It is against the rest treatment at present in vogue, as well as against one's feelings of sympathetic nursing.

The risk, then, of causing by operation an infection which would not otherwise occur is infinitesimal, and on all grounds my suggestion, wisely used in selected severe cases, seems a sound one, and I have convinced most of my colleagues with whom I have discussed the subject of its feasibility and utility. Very severe haemorrhage could be treated in advanced stations of field ambulances, less severe ones more comfortably in the small hospitals of the field ambulance and others, a diminishing number, in the casualty clearing stations.

In the only case in which I have done the operation great relief was experienced in breathing; there was a marked diminution of pain, and, though haemorrhage

could not be said to have been severe, it was still going on, and stopped quickly after the operation.

The operation may be done under a general or a local anaesthetic, and in any of the usual sites for empyema, preferably the mid-axillary line. Percussion localizes the haemothorax, and a stab is made with a scalpel through the intercostal space, close to the lower rib. The scalpel goes right into the pleural space. Even if the point of the knife wounds the lung, which is unlikely in most cases and impossible where there is much effusion, the consequence is negligible. The outer covering of one of the army tracheotomy tubes is slipped easily, owing to its central groove, one half along each side of the blade of the knife, and is pushed right home. The knife is then withdrawn and the centre piece of the tracheotomy tube put in. If air has not entered during the previous manipulations it will do so now, with a hissing noise, and the blood will be coughed out. The haemothorax may be aspirated through a soft catheter placed inside the tracheotomy tube, as was done in my case, but this would not be necessary in cases treated earlier, when clotting would not have taken place. The tube is now turned so that the inside end points up, and is fixed by straps and plaster or a suture to the chest wall. A pad of sterile gauze and wool completes the dressing. Mr. Lawrie, R.A.M.C., suggested that a trocar and cannula, such as is supplied in the pannier of the field ambulances and casualty clearing stations, would be sufficient to give relief and allow the patient to be transferred before more haemorrhage would take place. This is worth considering for advanced dressing station treatment. The cannula would, of course, not be left in.

When a tracheotomy tube is put in the whole operation does not occupy a minute, and the tube is removed after twenty-four or forty-eight hours, according to the amount of blood escaping. The wound closes immediately aseptically. Our patient went to the base on the third day quite fit.

The advantages of this treatment are—

1. The lung collapses quickly, and any wound in it immediately closes.
2. The lung gets complete rest for a time and will be better able to combat infection later, as it will contain very little blood effused into its tissues.
3. The suction force of respiration is immediately removed from the rents of the interthoracic vessels, and clotting and natural arrest is allowed to take place.
4. Plugging may be done for haemorrhage from the chest wall with a certainty of arresting it and of doing no harm, and there will be less movement—a comparative rest—on the collapsed side.

A SUCTION OR VACUUM BOUGIE FOR THE TREATMENT OF CHRONIC GONORRHOEA.

BY

CAPTAIN A. CAMBELL, R.A.M.C.(T.).

In chronic gonorrhoeal urethritis there are two conditions chiefly responsible for the failure, in many cases, of the usual methods of treatment. The one, is the gonococci are wholly or partially sealed up in the lacunae and glands, owing to the infiltration and thickening which has taken place round the walls. The other is, the great alteration in the vascularity of the mucosa by the infiltration resulting from the invasion of the gonococcus in the subepithelial tissue.

At this stage of the disease irrigations, injections, and other local applications are practically of no value, as they are unable to penetrate the glandular elements to wash out the lurking gonococci. Mechanical dilatation will not open the ducts or glands with infiltrated and thickened walls. The application of heat to the urethral mucosa by bougies fails to achieve its two objects, which are to kill the gonococci by the direct action of heat, and to induce an artificial hyperaemia, because the mucosa will not tolerate without injury the necessary temperature.

With the idea of inducing an effective hyperaemia in the subepithelial tissue, and promoting absorption, and also of emptying the lacunae and glands, I have designed a suction or vacuum bougie. I have used it in many

cases, and the results, I believe, justify further trial. It has been made for me by Messrs. Down Brothers. It consists of two parts—one, the bougie proper, A; and the other a tube or sheath-cone, B.

The bougie is a flexible tube made of wire wound spirally, the turns being in close contact. One end of the tube is closed by a metal tip, which is hollowed out for about $\frac{1}{4}$ in. from the end joining the wire. The wire is of such tension that although the bougie can be bent into a complete circle it readily returns to a straight line. The total length is 10 in., that of the tip being $\frac{1}{4}$ in. The sheath-cone is a metal tube about $2\frac{1}{2}$ in. long, enlarged at one end into a cone; the sketch shows the correct proportions. When the bougie is in the urethra the sheath-cone is slipped along it as far as the meatus, which it plugs automatically, preventing air from entering the urethra.

The manometer is a glass tube bent to form two limbs, and containing mercury. When at rest the column in the long limb registers the ordinary atmospheric pressure like a barometer. To the short limb is attached a glass T piece, the horizontal portion of which is fitted with a glass tap connected by tubing to an exhaust pump. The vertical portion descends to the base of the manometer, where it is bent at a right angle. To it is attached india-rubber tubing,

which leads to the glass and bulb C. The bulb is intended to catch urine, anaesthetic, etc., without removing the bougie. The glass tube is joined up to the sheath-cone by a short length of india-rubber tubing, so that the ends are in contact, the bore of the glass tube being large enough to admit the bougie. This is necessary in cases where the length of the bougie projecting from the meatus is more than 2 in., and also when it is used in the anterior urethra only. The india-rubber tubing used is $\frac{1}{4}$ in. thick with an internal diameter of about $\frac{3}{8}$ in.

Method of Employment.

The patient lies on a couch or table. If he has a small meatus, or has not previously had a bougie in the urethra, I syringe into the urethra a local anaesthetic (alypin 2 per cent.), and keep it in for five minutes. A No. 1 Lister's sound is now passed into the bougie as a stylet, the wire tube accommodating itself to the shape of the sound, the end of which fits in the hollow tip. I then lubricate the whole surface liberally with carbolyzed vaseline. It can now be passed into the urethra in the usual manner, just stopping short of the bladder. After withdrawing the sound, the sheath cone is fitted on to the bougie and pushed up to the meatus. The tap of the manometer being open, a few strokes of the pump will lower the atmospheric pressure in the urethra and suck the cone well into the meatus.

When the required pressure is reached by further use of the pump, the tap is closed. If all the joints are airtight, the mercury will only rise about 5 to 10 mm. in fifteen minutes. The pressure in the urethra is raised by disconnecting the pump and opening the tap slightly to admit more air.

I have obtained the best results with a height of about

100 to 200 mm. of mercury, maintained for fifteen to twenty minutes. If too low a pressure is used, it may cause bleeding. The bougie is withdrawn after disconnecting the pump and opening the manometer tap, and admitting air very slowly into the urethra. When the mercury is at rest, the sheath-cone is taken off, and the bougie withdrawn very carefully after giving it one or two twists. The patient then irrigates with 1 in 8,000 potassium permanganate, or protargol 1 in 4,000.

There is no pain or discomfort; if no anaesthetic is used the patient may be conscious of a slight sucking or drawing sensation.

The bougies are made in two sizes corresponding to No. 12 and No. 9 English. If the urethra will admit it the larger size produces a better result than the smaller.

On the bougie after removal may be seen small plugs of material which are found to consist of pus and epithelial cells, and very frequently gonococci. In some cases they are extremely numerous along the whole length of the instrument. They are caught in between the turns, and are more easily seen if the bougie is plunged into boiling water for a second. I regard them as a sign of successful action.

They have not always been obtained in cases which I expected would produce them. I believe now that it was due to the turns becoming clogged with vaseline, exudate, etc., and preventing suction.

It is essential that the bougie be kept scrupulously clean. Boiling is not sufficient. It must be soaked in petrol or syringed out, and occasionally a linen thread must be run between the turns.

To give one instance of its effect: a patient who contracted gonorrhoea three months previously had, on examination, only a slight muco purulent discharge. No gonococci were found in the discharge or urine. After one application of the bougie, numerous plugs were obtained in which were found gonococci. The discharge cleared up in a few days afterwards.

I hope shortly to be able to publish some further results.

I am much indebted to the friend who made the sketch for me, and to Lieutenant-Colonel L. W. Harrison, D.S.O., for affording me every facility for experiment with the bougies.

The manometer in the sketch was made by the Holborn Surgical Instrument Company.

TRENCH FOOT.

THE importance of this condition leads me to record the fact that in all the cases which have come under my observation in a small relief hospital here the men confessed to being the subjects of sweating feet.

Other factors are doubtless involved, but it is easy to conceive that the accumulation of this sweat, under conditions of warfare, would soon swarm with bacteria and become highly irritating to the skin and subcutaneous tissues. It would be interesting to observe whether "trench foot" selects the subjects of hyperidrosis.

To prevent or mitigate this localized hyperidrosis I have found the following treatment useful, in addition to the daily foot bath and change of socks:

1. Painting the feet with a solution of formalin.
2. A dusting powder composed of French chalk and zinc oxide, rubbed down with a few drops of formaldehyde and applied to the feet and inside of the socks.
3. A generous diet containing plenty of nitrogen.

J. G. BLACKMAN.

NEPHRITIS AND ADRENALIN POISONING.

SEEING the proximity of the adrenal gland to the kidney, and therefore the likelihood of this organ sharing the congestion of the kidney in nephritis, and bearing in mind that adrenalin can produce arterio sclerosis, arterial degenerations, and vascular hypertension, I would venture to make the tentative suggestion that hypertension and

arterial disease in nephritis are due to adrenalin auto-poisoning. As far as I am concerned, this suggestion is original.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

At the third general meeting of the session, held at Wolverhampton on April 27th, the President, Dr. F. M. ROWLAND, was in the chair.

Splenectomy for Banti's Disease.

Mr. CHOLMELEY showed two cases of splenectomy for Banti's disease:

CASE I.—Boy, aged 6 years; ailing for three years; very pale and languid, getting thinner; has pain in epigastrium, cough, and occasional haematuria. The spleen was fairly large, also the liver; the boy was very pale, skin rather yellow, slight icteric tinge of the conjunctiva. On January 19th a blood count was taken: red cells, 1,350,000; white, 6,500. On January 21st the spleen was removed; it was not exceptionally large; the liver was very much enlarged. The next day the colour of the skin had changed; there was a healthy pink tinge in the lips, ears, and cheeks. On February 7th the blood count was: red cells, 2,700,000; white, 11,000. The boy was discharged from the hospital on February 14th very much improved. The improvement had not been maintained; he still looked very pale and weak. Blood count on March 9th showed: red cells, 2,425,000; white, 15,600; haemoglobin 70 per cent.

CASE II.—Boy, aged 12 years. Illness started suddenly after a fright a week before he was seen. The boy was very pale; no icterus, no haematuria; complained of pain in abdomen, back, and head. Spleen very large. Blood count, February 14th: Red cells, 1,330,000; white, 5,000; haemoglobin, 35 per cent. The spleen was removed on March 4th; it weighed 2½ lb. A blood count taken on March 15th showed red cells, 2,900,000; white, 10,000; haemoglobin, 70 per cent. The boy was discharged on March 19th, very much improved. The improvement in this case was much more marked and better maintained, the blood count on April 26th being: red, 2,800,000; white, 53,000; haemoglobin, 60 per cent. The great difference in the after progress of the two cases was due most likely to the difference in the length of previous illness.

Insurance Act Developments and Problems.

After a brief reference to the various medical interests served by the British Medical Association and of the accusations levelled at it by discontented groups of practitioners, Dr. MACTIER took up the subject of the recent developments in National Insurance, and also gave a few examples of problems which had come under his notice. Dealing first with the subject of certification, he said that the profession in many cases had either failed to understand Memorandum 211/I.C. or had not read it; the approved societies were also to blame in that their agents, especially those of the collecting societies, had not been instructed in the rules, and the fact that they still insisted on certificates being given on certain days of the week led to trouble, and proved annoying to those practitioners who were conscientiously carrying out the rules. The question of certificates for patients at hospitals was next dealt with, and it was pointed out that any officer, not necessarily a medical officer, could give a certificate to the effect that so-and-so was an in-patient of the institution. But with regard to out-patients, the view was expressed that the practitioner on whose list the patient was was bound to furnish the necessary certificates, whereas there was no obligation to do so on the hospital staff. Practitioners were warned that certificates should be given with care and dated on the day on which the patient was examined, since failure to comply with this rule had given rise to more complaints for investigation by the Medical Service Subcommittee than any other cause. In discussing the drug tariff, he gave a short description of the work of the West Midland Pricing Bureau at Birmingham, which is responsible for the pricing of the prescriptions payable by eighteen Insurance Committees and employs a staff of some twenty persons. The insertion without notice in the 1916 agreements of the clause as to the use of "Rep. mist." and the use of indelible ink for certificates was mentioned; Dr. Mactier said the Bureau looked on "Rep. mist." with great favour, provided the original script was attached and it did not go outside the

calendar month. He concluded by stating a few problems which had come before him as Chairman of the Wolverhampton Insurance Committee, and agreed with an expression of opinion by the meeting that knowledge which was obtained as referee should not be used in the capacity of chairman when considering the question of adequate service being given by panel practitioners.

Coolidge Tube.

Dr. J. A. COOD described and demonstrated the "Coolidge tube," which, he said, he had had for about ten months, and found that for purposes of treatment it was far superior to the best type of ordinary tube. It was a machine of precision. If a result with a given series of factors was once obtained, it was possible to reproduce it by repeating the factors, which were completely under control. The main facts of construction and manipulation were then described. The factors of the working equation were: (1) Distance of diseased area from target, (2) hardness or penetration of tube, (3) current through heating circuit of cathode, (4) coil current through tube, (5) ohmic resistance in primary current, (6) filter, (7) time, (8) dosage shown by colouring pastille or other form of measurement. If (1) to (7) were reproduced, (8) would always be the same. A series of observations showing this was handed round. He pointed out that in (5) he mentioned "ohmic resistance in primary" instead of "current in primary," as the latter was no guide, because as less and less ohmic resistance was included the hardness of the tube increased and the resultant inductance in the primary increased so much as almost to neutralize the decreased ohmic resistance. Thus, in throwing off the resistance from the ninth stud to the fifteenth, decreasing the ohmic resistance from 86 ohms to zero, the primary current only increased from 6 to 6.5 amperes. So in factor (5) he used the expression "stud n," the ohmic resistance of which was known, and could be recorded in all publications, so as to compare with the work of other workers. His recent practice had been the following:—For deep structures: (1) 15 cm., (2) 19 cm spark-gap, (3) 4.2 ampères in heating circuit, (4) sixth stud (15.5 ohms), (5) 5 milliamperes, (6) 3 mm. Al, (7) 10 min.; this gave 14 Hampson at half distance, covered with filter. For superficial lesions, 0.2 mm. Al was used, and for ringworm no filter, and four minutes gave 14 Hampson, which was all that was needed for epilation, and no more should be given. Probably less was enough. The use of the Coolidge was very comforting in ringworm cases, as there was no dread of sudden variation in the tube and too rapid colouring of the pastille, as had happened in other tubes. By using the same dosage as in ordinary tungsten-target tubes, even though he had increased the filter from 2 to 3 mm. Al, he had had the misfortune to burn three of his cases. He did not think it safe to give more than 14 Hampson a week, and probably less frequently than this would be found to be necessary. For radiography he had not found his tube to be of much service, though for the screening of opaque meals it was useful. At first he found it self-rectifying, but recently had had to use valve tubes.

Diaphragmatic Hernia.

Mr. CHOLMELEY showed the left half of the diaphragm from an infant three hours old who died suddenly. The infant was a very healthy-looking baby and was left quite well by the midwife about two hours after birth. It died quite suddenly an hour later. At the *post-mortem* examination nearly all the small intestine, the spleen, and nearly the whole of the stomach were found in the left chest, having escaped from the abdomen through a congenital defect in the left half of the diaphragm. The opening was in the back of the diaphragm, oval in shape 2 in. in its long diameter.

ACCORDING to statistics recently published by Dr. Shibasahuro Kitasato, the death-rate from tuberculosis for the whole of Japan is 17 per 10,000. It is considerably higher in certain occupations, notably among school teachers. Among factory girls, of whom there are some 500,000 in the country, there is an average of 9,000 deaths a year, of which 6,300 are caused by tuberculosis. Most of the girls live in overcrowded and ill-ventilated dormitories. The prevalence of tuberculosis in Japan is ascribed to the number of houses in low areas into which the sunlight rarely penetrates and the traditional custom of tightly closing all windows during the night.

Reports of Societies.

THE RATIONALE AND PRACTICE OF CHEMOTHERAPY.

THE Dermatological Section of the Royal Society of Medicine on June 1st continued the discussion on Mr. J. E. R. McDonagh's communication,¹ which had been adjourned, special attention being paid at this meeting to the clinical side. Mr. McDonagh in his opening remarks extended and in part modified his previous statements. He pointed out that ferrivine was adapted for treating the acute stages of syphilis, and intramine for the chronic cases; these drugs surpassed salvarsan in general, but while in some cases of early syphilis ferrivine was better than salvarsan, in others it was less efficient. The behaviour of the early lesions in cases treated with ferrivine differed from what was observed with salvarsan; after ferrivine the chancre became swollen and did not heal so quickly, but there was an absence of induration, and lymphangitis and the swelling of the inguinal glands receded rapidly. It appeared that congenital syphilitic keratitis did not invariably respond to intramine. He emphasized his opinion that, although salvarsan removed the symptoms of syphilis, it did not cure the disease. The disadvantages attendant on the administration of ferrivine owing to the shock produced by the drug had now been overcome.

Dr. PRINGLE said that he had observed the action of ferrivine in two dozen cases treated in Mr. McDonagh's out-patient clinic at the Lock Hospital. Measuring the result of the remedy by its action on the primary sore, he regarded the effects as more striking and more immediate than after arsenical preparations. The subsidence of the induration of the chancre and of the lymphangitis and lymphadenitis was remarkably rapid. Intramine had been tested by himself in secondary and tertiary cases; and while it was not possible to form such a positive estimate of its effects, he, on the whole, endorsed its adjuvant action when administered in conjunction with arsenical products or ferrivine. In early cutaneous syphilis it accelerated the disappearance of hard nodular and follicular lesions. Intramine should not be given at too short an interval after an arsenical compound. In one case which he had observed, an injection of intramine administered within twenty-four hours after a moderate dose of galyol had apparently induced acute symptoms of galyol poisoning. Late superficial cutaneous syphilides often disappeared, at least temporarily, after an injection of intramine, but it was yet too early and the number of cases too limited to warrant conclusions regarding the permanence of the action. A serious disadvantage of intramine was the severe pain which it produced, although not invariably, and which incapacitated the patients for a week; in most cases they would not be persuaded to receive a further dose. Dr. Pringle commented on Mr. McDonagh's attitude in rejecting the Wassermann reaction. Personally, he had found it a valuable aid in diagnosis in doubtful cases and also as a guide in treatment.

Lieutenant-Colonel HARRISON described the effects of intramine and ferrivine as observed along with Mr. C. H. Mills. Ferrivine, as obtained from the manufacturers, was tested in three cases; two of these received intramine in addition. They were ordinary cases of early syphilis. In spite of the repeated doses of ferrivine, the cases behaved just as if no specific treatment of any kind had been received; spirochaetes continued to be found in the secondary lesions, and in one patient a mucous patch containing spirochaetes developed on the tonsil during the treatment with ferrivine. The immediate beneficial effect of a single dose of salvarsan administered later showed that a refractory infection was not being dealt with. As regards the side-effects of ferrivine, Colonel Harrison referred to the extremely serious nature of the symptoms; great collapse and respiratory distress, etc., occurred rapidly after the injection of the ordinary dose, and one case appeared on the point of death. The local effects of intramuscular injections of intramine, when administered by the most perfect technique, and without any addition of

urea or quinine, were "undiluted torture"; in eight cases which had received intramine the symptoms had been practically uniform, with local swelling and tenderness, which persisted for weeks. In one case an abscess formed which had now been discharging for twelve weeks; in others there was evidently necrosis, although no abscess had formed yet. Colonel Harrison regarded the use of intramine as impracticable on account of its local effects; as to its therapeutic action, he recalled the fact that tertiary lesions might be markedly benefited by a great variety of measures which could not be termed specific, such as hot applications.

Dr. SEQUEIRA was of opinion from his own experience that nothing approaching the therapeutic effect of salvarsan and its analogues was produced by ferrivine and intramine. In the secondary stage of syphilis these drugs could not be compared with the arsenical products. In a case in which he had administered a dose of not more than 1 gram of ferrivine obtained from the makers, toxic symptoms followed practically immediately, and the man appeared near to death. Vomiting occurred before there was time to take the needle out of the vein; Dr. Sequeira regarded ferrivine as the most rapid emetic he had yet seen. Intramine produced very severe pain and five to six weeks afterwards massive tender swellings were present just like those following the intramuscular administration of salvarsan.

Dr. SHILLITOE quoted results obtained with ferrivine and intramine at the Female Lock Hospital. Four out of nine cases showed very marked improvement; two reacted severely to ferrivine; intramine caused severe pain in six. He considered that ferrivine and intramine did exert an antisiphilitic action, which in some instances was as rapid as after salvarsan.

Dr. H. G. ADAMSON had tested intramine in lupus. Eight cases had received sixteen injections in all; the first two cases showed remarkable improvement with healing of the ulceration; but it was much too early yet to give an opinion on the effects.

Mr. C. H. MILLS reported further details of the cases treated with Colonel Harrison, and confirmed the points already mentioned. A case of indurated chancre of two months' duration, with mucous patches, received a full dose of ferrivine, which caused an immediate severe reaction; in spite of repeated treatment spirochaetes were still present in the mucous patch more than one week after the commencement of ferrivine administration. Then a dose of salvarsan was given, and eighteen hours later no spirochaetes could be found. The reaction following the intravenous injection of ferrivine was more severe than any observed during nine thousand injections of other preparations. With regard to the patients exhibited by Mr. McDonagh, Mr. Mills pointed out that one who had been under treatment for two months exhibited mucous patches and that in two cases intramine had become encysted.

Sir MALCOLM MORRIS urged on Mr. McDonagh, with regard to these new products, the same policy of watchful waiting which Mr. McDonagh himself had advocated in the case of salvarsan. Dr. C. H. BROWNING commented on the conflicting character of the evidence derived from the observation of cases treated by Mr. McDonagh when compared with the results of others who had themselves tested ferrivine. Dr. STOWERS, the President of the section, also emphasized the necessity for postponement of conclusions.

In reply, Mr. McDonagh complained that his researches had neither been proved nor disproved by his critics. He admitted that intramine and ferrivine were capable of improvement, and stated that improvements had already been effected. He doubted whether the chemical aid necessary for the perfecting of his work could be obtained in this country.

INJURIES OF PERIPHERAL NERVES.

At the meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on April 7th Major F. C. PURSER read a paper on injuries to peripheral nerves. He showed first what might be expected in a nerve which was wholly divided and then sutured under the most favourable conditions. Wounds caused in war seldom had so good an ending. They might be divided roughly into two classes—a numerically smaller class of total loss of function and a larger class where function was not wholly lost. A case in either class, but especially in the latter

¹ BRITISH MEDICAL JOURNAL, April 22nd, p. 591.

class, might be associated with pain or with hyperaesthesia. In the first class, with total loss of power and of sensation, the question to make sure of first was that the lesion was organic, of a nerve or nerves, and not functional. Having decided this, the exact outline of sensory loss and extent of motor loss should be recorded. If there were no improvement in six weeks or two months, exploration of the nerve was justified. Partial loss of function varied in severity of its symptoms from a loss almost total to a mere subjective sense of abnormality. Motor loss, as far as it could be compared with sensory loss, was often disproportionately great. Improvement in the condition of a case might, he said, best be gauged by an exact examination of sensory changes. Cases were described illustrating this point. Either total or partial loss of function might be due to anatomical section of nerve or to the inclusion of the nerve in scar or other compressing tissue. Recovery following secondary suture was far less satisfactory than that following the release of the nerve from scar tissue. Operation was called for when the disablement was very great and was not lessening under proper relaxation and massage treatment and when pain was severe. Often enough it made matters worse, and should not be undertaken without very careful repeated consideration of the case.

Mr. W. S. HAUGHTON followed with a paper on bullet injuries of nerves and other treatment. He dealt chiefly with the mechanical effects of high-velocity bullets striking the tissues, and described the different types of lesion that resulted in the nerves in the neighbourhood of wounds.

Reviews.

THE PATHOLOGY OF TUMOURS.

DR. E. H. KITTLE is to be congratulated on having produced a very useful volume on *The Pathology of Tumours*.¹ His aim has been to follow the generally accepted teaching, and this he has set forth clearly and succinctly, omitting all highly controversial theoretical matter and weighing carefully in the light of his own practical experience the *pros* and *cons* of those subjects on which there is still no general agreement. It is in the chapters on the endotheliomata and the hypernephromata, especially the latter, that the author's own views become more manifest. He does not side with those who regard the endotheliomata as tumours of general and frequent occurrence. The section on the hypernephromata is perhaps the best in the book. From a careful consideration of the histological features of these growths the author is forced to the conclusion that many of the so-called hypernephromata are really renal in origin.

The book is divided into three parts. The first deals with the general biology, the second with the general pathology, and the third with the special pathology of tumours. In the section on dissemination the author states (p. 22) that "an operation for the cure of cancer can only be successful when the whole of the growth is removed; if a single metastasis is overlooked, the proceedings are doomed to failure." Without any desire to appear captious, this statement seems unduly gloomy. It must have fallen to the author's lot to have met with cases in which a malignant nodule has disappeared spontaneously. Furthermore, on page 25 is the statement that the perilymphatic reaction may eventually "choke and kill" the cancer cells spreading along one of the larger lymphatic vessels. Provided that extension of growth from the distal end of such a plug does not occur—and this is an occurrence which, though common, is by no means inevitable—the nodule may die out. It must also be accepted that not every metastasis "takes" owing to unsuitability of environment.

It is refreshing to find a grave word of caution against the practice of the "rapid diagnosis" of tumours by means of frozen sections prepared whilst the patient is still under the anaesthetic, and the author's views will probably find acceptance with many pathologists who have had practical experience of this kind of work.

¹ *The Pathology of Tumours*. By E. H. Kittle, M.D., B.S. Lond. London: H. K. Lewis and Co., Ltd. 1916. (Demy 8vo, pp. 232; 126 figures. 10s. 6d. net.)

The one disappointing feature about the book is that it follows so rigidly the generally accepted teaching. The research worker and the advanced student will probably not find in it new stimuli. On the other hand, the busy general practitioner and the final-year student have been given just what they want to make them familiar with this most interesting and important branch of pathology.

A very special word of praise must be given to the illustrations. Of the 126 figures about 100 are of microscopical sections, and have been specially drawn for the book. They are admirably chosen and beautifully reproduced. The book is of convenient size and excellently printed.

AN OXFORD WAR PRIMER.

THE small pocket guide on *Injuries of the Eyes, Nose, Throat, and Ears*² is one of the Oxford War Primers of medicine and surgery published under the general editorship of Lieutenant-Colonel D'ARCY POWER. Dr. MAITLAND RAMSAY, in his introductory remarks to the section dealing with injuries of the eyes, writes: "In modern warfare eye injuries are of very frequent occurrence, but, whatever their cause . . . it may be taken that they differ merely in degree, and not in kind, from those met with in ordinary civil life. The principles that underlie treatment are, therefore, the same in both instances." After reading the book this remark appears to be applicable to the other sections. Apart from a series of illustrative cases appended to the section of injuries of the nose and throat there is little in the book that might not have been published had there been no great European war.

Out of 156 pages of text only ten are devoted to the injuries of the ears. The large number of men, not only from the trenches at the front but also from the training camps and barracks at home, suffering from injuries and diseases of the ears, show that the subject is of more importance than could have been anticipated, and deserving of more attention than the space accorded to it in this primer allows. In support of this opinion we may quote from Mr. West's concise contribution. Speaking of deafness ascribed to war causes he writes: "Mental obstructions by ceruminous plugs are not uncommon. It seems likely that some of these are truly 'explosion deafnesses' owing to the plug having been driven home by the sudden compression-wave. Such plugging of the meatus seems to give complete immunity from damage to the cochlea, and the case is cured by the syringe. These cases have, however, repeatedly been sent home from France for want of a simple diagnosis." The primer contains much teaching in a condensed form. To those who have grown out of touch with the special departments of practice with which it deals and find themselves on active service it will be a useful guide.

THE ORDER OF ST. JOHN OF JERUSALEM.

THE story of the Knights Hospitaller, the most ancient order of chivalry, and its revival in England, was told in the *BRITISH MEDICAL JOURNAL* of October 24th and 31st, 1914. The head quarters of the reconstituted body are in the old priory of the order at Clerkenwell, a description of which was written some years ago by the Rev. T. W. Wood and Mr. H. W. FINCHAM. More recent discoveries having made that *Guide* out of date, Mr. Fincham has embodied the results of fresh investigations in an interesting volume which has recently appeared.³ As the sphere of more important duties of the Order was in the Mediterranean, the Priory of England, he thinks, must have been used mainly for the princely hospitality which it dispensed, for the administration of its great estates, and for recruiting. He gives a full account of the old buildings as far as they can now be traced. Little now remains, but Stow and other old writers have said that they were stately and beautiful. The old priory suffered many vicissitudes. After the dissolution of the monasteries it was preserved as long as Henry VIII reigned, though degraded to base

² *Injuries of the Eyes, Nose, Throat, and Ears*. By A. M. Ramsay, M.D., F.R.C.S. (Glasg.), Major R.A.M.C.(T.F.); J. Dundas Grant, M.D., F.R.C.S. (Eng.), late Major R.A.M.C. (Post Office Volunteers); H. Lawson White, M.D. (Camb.), F.R.C.S. (Eng.), Captain R.A.M.C.(T.F.); and C. E. West, F.R.C.S. (Eng.), Captain R.A.M.C.(T.F.). Oxford War Primers. London: H. Frowde, Hodder and Stoughton. 1915. (Fcap. 8vo, pp. 160; 11 figures. 2s. 6d. net.)

³ *The Order of the Hospital of St. John of Jerusalem, and its Grand Priory of England*. By H. W. Fincham. Member of the Order of St. John. London: W. H. and L. Collingridge. (Cr. 4to, pp. 88, illustrated. 6s. net.)

uses, being made a storehouse for "the king's toils and tents for hunting." In the reign of Edward VI the church, with the great bell tower, "a most curious piece of workmanship, graven, gilt, and enamelled, to the great beautifying of the city," says Stow, was blown up with gunpowder. In Queen Elizabeth's time the priory was the head quarters of the drama, and from there Edmund Tynney, the Master of the Revels, licensed thirty of Shakespeare's plays. At the beginning of the eighteenth century the chapel had become a Presbyterian meeting house; then it was a private chapel for the use of the neighbourhood, and in 1723 it was reconsecrated as the parish church of St. John of Clerkenwell. In 1731 the Gate House was inhabited by Edward Cave, who there printed and issued the *Gentleman's Magazine*. There Samuel Johnson hid his shabbiness behind a screen when there was company at dinner. In 1845 the building had become so ruinous that the metropolitan building authorities ordered its thorough repair or demolition. Mr. W. P. Griffith, an architect resident in St. John's, raised a public subscription, and eventually restored the building to a safe condition. In 1874 the freehold of the Gate House was bought by Sir Edmund Lechmere, who later transferred it to the Order. Mr. Fincham gives a detailed description of St. John's Gate and of the church and crypt, with the heraldic shields and other decorations and the historic memorials which they contain. The crypt was the scene of the performances of the "Cock Lane Ghost," which in 1772 attracted royalty, nobility, members of Parliament, and leaders of fashion to hear the noises made by "Scratching Fanny."

Mr. Fincham has little to say about the hospital work of the knights in their early days. Although the Order became within no long time of its foundation more a fighting than a nursing body, it seems to have retained all through its history some traces of its original character. The revived English Order gives itself wholly to works of charity, and through its ambulance department the St. John Ambulance Association and the Brigade, which is an offshoot, it has done and is doing work of incalculable value in the present war. The account of that work given by Mr. W. R. Edwards, secretary of the Order, is a proof of the splendid enthusiasm of humanity that animates the hospitaliers of to-day.

Mr. Fincham's book should be read by all interested in the fascinating history of the soldier monks who through many centuries ministered to the sick and fought the infidel at Jerusalem, Acre, Cyprus, Rhodes, and Malta, by all students of the development of philanthropy, and by all lovers of old London. It is admirably and abundantly illustrated, and the plans of the church and other buildings enable one to follow the work of restoration to the present time, when, though much of the material glory has departed, the original spirit breathes in the workers who have taken up the heritage of the knights of old.

PATHOLOGICAL ENTOMOLOGY.

THE last five years have witnessed the publication of a comparatively large number of books on medical entomology; none of them are entirely satisfactory, partly because they are apt to be out of date shortly after publication, but much more because the subject is very composite, bearing as it does on clinical medicine, public health, the protozoa, the bacteria, and systematic and biological entomology. Probably we must recognize that the successful textbook on medical entomology will be the work of a number of authors each dealing with a section of the subject. Applied entomology is as yet very inadequately recognized by the medical profession. One wonders, for instance, how many students have ever seen the scabies mite, or have such a knowledge of the life-history of fleas as would enable them to rid a house of that pest. It is not, of course, suggested that the ordinary medical man should do more than make himself acquainted with the dozen insect parasites of man which are met with in this country, but we hope that in the future the medical entomologists will be recruited as often from the hospitals as from the schools of zoology.

Professor HERMS's *Medical and Veterinary Entomology*⁴

⁴ *Medical and Veterinary Entomology: A Textbook for Use in Schools and Colleges as well as a Handbook for the Use of Physicians, Veterinarians and Public Health Officials.* By W. B. Herms. New York: The Macmillan Co. 1915. (Roy. 8vo, pp. 405; 228 figures. 15s. net.)

is written primarily for the American student, and gives a very good account of the parasitic insects, especially those which spread disease among men and animals in America. The author shows much wisdom in omitting as far as possible systematic tables for separating the scores of known species of tick, or mosquito, or flea. Only a few of these species are of great pathogenic importance, and no one should attempt to identify an Anopheline, for instance, without a considerable training in the systematics of that group. Most parasitologies and handbooks of medical entomology do not recognize this, and we fear that the result will soon be seen in the publication of a large crop of mistaken identifications, based on the use of the "keys" of these books. The author's wisdom in saying so little about the internal anatomy of the more important parasites may be questioned, but he may have felt that Patton and Cragg's *Textbook of Medical Entomology* dealt with this aspect of the subject so fully that he was justified in omitting it from his smaller work. A great deal of modern work in tropical medicine turns on the dissection of parasitic arthropods; we refer, of course, to such work as Bacot's on the *Bacillus pestis* in the gut of the flea, Patton's search for *Leishmania* in the bed-bug, Fantham and Porter's investigations upon *Herpetomonas* in insects, or the fruitless search of many workers for *Piroplasma* in any or every organ of the infective tick. A good knowledge of the internal anatomy of pathogenic insects and of the readiest means of dissecting them is necessary to a comprehension of this work.

After some introductory chapters, Professor Herms describes the insects with which he is concerned, in systematic sequence. A great number of species of lice, both true lice and biting lice, infect man and the domestic animals; the majority of these are figured, most of them from photographs. Some of the photographs should never have been published; no good purpose is served, for instance, by figuring a *Trichodectes* without visible legs or abdominal segments; some of the photographs are excellent, as are also the line drawings. The Diptera (fleas and true flies) occupy more than half the book. The author has very wisely confined himself to the more important members of this vast order. The account of the house-fly and the anti-fly campaign is particularly good, as, indeed, it should be in a book published in America. Professor Herms has not provided a separate bibliography, but gives his references in footnotes. He ought to have found room for some reference to Dr. Graham-Smith's invaluable volume on *Non-biting Flies*.

The ticks and mites, though they are not actually insects, are conveniently included in any book on applied entomology. Ticks are of the greatest economic importance in America, and indeed in many other parts of the world, for they are responsible for the transmission of the *Piroplasma* group of protozoa, the organisms of "red-water" and kindred disorders in the domestic ungulates.

Professor Herms is not, apparently, a medical man, but he is by no means one of those entomologists who believe in the insect transmission of "every ailment, from a gumboil to a dislocated spine." He adopts the view, which we believe to be correct, that poliomyelitis is not normally transmitted by *Stomoxys*; on the other hand, he follows Sambon in the matter of the transmission of pellagra by *Simulium*.

The index is good, the figures are numerous, and some of them excellent. The volume is extremely heavy.

NOTES ON BOOKS.

THE seventh edition of GOULD's *Pocket Medical Dictionary*⁵ has recently appeared, and shows an advance on its predecessors. Thus, for example, the fourth edition, dated 1900, contained definitions of some 30,000 words, as compared with the 35,000 in the seventh edition, which also contains many more lists and tables than the edition of 1900. At the end of the book there is a posological table of the commoner drugs, and a veterinary dose table. The print and paper are satisfactory, and there is no doubt that the book contains a vast amount of information.

Mr. J. S. KELLETT SMITH has written a short and optimistic account of his experience with the Bergonié

⁵ *A Pocket Medical Dictionary.* By G. M. Gould, A.M., M.D. Seventh edition, revised. London: H. K. Lewis and Co., Ltd. 1915. (Pott 8vo, pp. 1003. 6s. net.)

electrical treatment of obesity and what he calls "obese heart."⁶ Details are supplied of the way in which the interrupted induced current is applied, and a few pages are given to the association of obesity with diminished functional activity of the thyroid gland. The author prescribes for patients receiving the electrical treatment a diet containing little fat or carbohydrate. He adds that obese people should reduce the total consumption of fluids to a low level, particularly at meals. A number of weight charts reproduced in the book show that satisfactory reductions of weight may be obtained by the methods advocated.

⁶ *The Cure of Obesity and Obese Heart.* By J. S. Kellett Smith, F.R.C.S. Eng. London: J. and A. Churchill. 1916. (Cr. 8vo, pp. 101; 12 figures. 3s. 6d. net.)

MEDICAL AND SURGICAL APPLIANCES.

Silver-wire Drainage Tube.

CAPTAIN VELLACOTT, R.A.M.C., has devised a silver-wire drainage tube which resembles a test tube in shape, for which the following advantages are claimed:

1. The tube allows air or oxygen to reach the tissues more freely than other tubes.
2. Irrigating lotions also reach the tissues in the same manner.
3. Discharges pass freely into the tube along its whole length.
4. The tube is non-compressible and unbreakable. It is especially useful in the septic wounds of war.

The tubes are made by Messrs. Down Bros. in various sizes from 2 inches to 8 inches in length.

SUPPLY OF PETROL.

THE Petrol Control Committee of the Board of Trade has issued a memorandum in the course of which it is stated that a subcommittee, consisting of representatives of the chief distributing organizations, has undertaken to regulate the supply of petrol according to the classification shown below.

Users of motor spirit have been placed in three classes:

Class "A" includes cars used by medical practitioners, veterinary surgeons, cars used by recognized organizations for the transfer of sick and wounded, for the transport of munitions of war, by the police and local government authorities, by lord lieutenants and high sheriffs, or for any service certified by a Government department.

Class "B" includes requirements for agricultural machinery, industrial processes, and the conveyance of goods, for air craft, for motor cabs, for motor cars used by commercial travellers, for boats and omnibuses used for other than pleasure services, for railway purposes, and for stationary engines, including lighting sets.

Class "C" comprises all other requirements, including private motor cars and motor cycles in ordinary use.

It is not anticipated that there need be any curtailment at present of reasonable demands in Classes "A" and "B."

The same memorandum calls attention to the regulations limiting the amount of motor spirits which may be stored without a licence, and states that it is the intention of the Committee shortly to take a census of all motor vehicles and of petrol consumption and requirements.

It is stated on what seems to be good authority that the military services now need nearly, if not quite, as much petrol as was consumed in the United Kingdom for all purposes before the war. At the same time the amount used by commercial vehicles is believed to have increased. If these statements be correct the Petrol Committee's expectation that it will be possible to keep up the supply for Classes "A" and "B" would seem to be, in part at least, founded on the reply made to a question in the House of Commons on May 31st by the Parliamentary Secretary to the Board of Trade, to the effect that a recommendation had been received from the Committee with regard to the release of certain tank steamers to facilitate the importation of additional supplies. It is said that at the present time, owing to lack of adequate storage on shore, tank steamers are kept in port, where they are gradually emptied to meet the demand.

The Automobile Association and Motor Union has produced evidence to the Petrol Control Committee on two points. One is that, from a special inquiry addressed to their members, it would appear that 58 per cent. of mileage is entirely for business or professional work, and 16 per cent. for voluntary work; the remaining 26 per cent. is for shopping, station work, and otherwise in the private interests of the owner; it is added that a recent census of traffic on main roads showed that the number of pleasure cars on the road was a negligible quantity. The other point is with regard to the ten million gallons of duty-free petrol delivered last year for industrial purposes. It is suggested that while petrol is a necessity for motor vehicles, it may not be indispensable in certain industries where a substitute or a heavier grade of spirit could be used. It is suggested that the Petrol Committee should obtain an independent technical opinion on the utilization of substitutes for industrial purposes, and it is pointed out that every gallon of petrol so released for private business would produce 6d. for the Treasury. The hope is also expressed that if the restriction of supply is imperative in the national interest, the Petrol Committee will take steps to protect private users against unreasonable increases in price.

The Medical Secretary of the British Medical Association has received a letter from the Petrol Control Committee, dated June 2nd, stating that the Committee has made arrangements with the principal petrol supply companies whereby the requirements of medical practitioners are to be met in priority to the requirements of the majority of other users, and that it is hoped that the full operation of this arrangement will remove the difficulties which have been experienced by medical men.

The following communication has been received by the Local Government Board (Ireland) from the Major-General in Charge of Administration, Irish Command, with regard to the regulations now in force as to the sale of motor spirit in Ireland:

DUBLIN CITY.—All restrictions regarding the sale of motor spirit have been removed.

OTHER PLACES IN IRELAND.—There are no restrictions excepting that persons can only obtain petrol through the local police authority; therefore, any difficulties experienced by would-be purchasers should be referred by them to the Inspector-General, Royal Irish Constabulary, as there is no limit to quantities which vendors may remove by authority from Dublin.

BIRTHDAY HONOURS.

THE list of honours published in the *London Gazette* in connexion with the King's birthday include the following civil members of the medical profession in addition to naval and military members, whose names are published at another page:

Dr. Addison, M.P., Parliamentary Secretary to the Ministry of Munitions, has been created a privy councillor.

The honour of knighthood has been conferred upon Mr. Francis Mark Farmer, dental surgeon to the London Hospital; Dr. M. Armand Ruffer, C.M.G., president of the International Quarantine Board, Egypt; and Professor Nestor Tirard, secretary of the Pharmaceutical Committee of the General Medical Council.

Dr. Frederick Montizambert, I.S.O., Director-General of Public Health, Canada, receives the distinction of C.M.G.

Dr. Noel Bardswell, medical superintendent, King Edward VII Sanatorium, Midhurst, and Dr. Frederick S. Hewett, Surgeon Apothecary to His Majesty the King, have been appointed members of the fourth class of the Royal Victorian Order.

The Kaisar-i-Hind gold medal is bestowed upon Mr. H. M. Newton, F.R.C.S., Church of Scotland Mission, Jalalpur Jatan; Dr. M. G. Robertson, chairman of the Municipal Committee of Ajmer; and the Rev. Peter Cullen, M.D., Brigade Surgeon, I.M.S. (retired).

AT Whitsuntide a new naval ambulance train, lately completed at the L. and N.W. Railway Works to the specification of the Admiralty, will be on view at Addison Road Railway Station, near Olympia. Cots can be shipped aboard it in such a manner that the seamen will be transferred undisturbed in them from the ship to the hospital. A charge of one shilling will be made for admission, and the proceeds will be handed over to the Dreadnought Hospital for Seamen, Greenwich.

British Medical Journal.

SATURDAY, JUNE 10TH, 1916.

UNDER FORTY-ONE AND UNENROLLED.

It is of the utmost importance that medical men under the age of 41 should understand at once the position in which they are placed by the Military Service Act (Session 2), which became law on May 25th last. The Regulations made under it by the Order in Council of June 1st are printed in full in the SUPPLEMENT.

Every male British subject, married or single, who has not attained the age of 41 before June 24th next, will (with certain exceptions, which do not concern the medical profession) be deemed, as from that date, "to have been enlisted in the regular forces for general service with the colours or in the reserve for the period of the war, and to have been forthwith transferred to the reserve."

Application for exemption from the provisions of the Acts may be made by a medical man to the Local Tribunals, but such application is only necessary in the case of the unenrolled man. The enrolled man, if called up, need only produce his certificate of enrolment and refer the recruiting authorities to Army Council Instruction 485. The applications of medical men will be referred to the Professional Committees appointed under the Regulations. Application for exemption must be made to the Local Tribunal before the "appointed date," that is, before June 24th, 1916. The Professional Committees are the Central Medical War Committee for England and Wales, the Scottish Medical Service Emergency Committee for Scotland, and, in certain special cases, the Committee of Reference appointed by the Royal College of Physicians and the Royal College of Surgeons. A Central Professional Committee has power to recommend exemption—absolute, conditional, or temporary—in cases in which, after considering the evidence, it thinks a certificate of exemption ought to be granted, and the recommendation of the Professional Committee concerned will be binding on the Local Tribunal.

In England and Wales medical men of military age may be divided into those who enrol with the Central Medical War Committee and those who do not enrol. It is with the latter class that we are concerned at present.

The medical man who is under the age of 41 on June 24th next, who is unenrolled and does not intend to enrol with the Central Medical War Committee before that date, may do one of two things. Either he may wait until his class is called up by the military authorities, in which case he will be taken for general service, and if found suitable is not unlikely to be offered a commission in the R.A.M.C., or he may apply to a Local Tribunal for exemption provided he does so before June 24th. If he waits to be called up, he will be taken for the duration of the war just like any other citizen, and his pay will be at the ordinary rate for the kind of service into which he is taken. If he is given a commission his pay will be the ordinary pay of a lieutenant in the R.A.M.C.

Presumably, however, the unenrolled man will usually apply for exemption. In this case his application will be forwarded by the Local Tribunal to the Central Professional Committee; if he is attached to a metropolitan hospital, the application will be transmitted to the Committee of Reference. The recommendation made by these Committees will be returned to the Local Tribunal and will be binding on the Tribunal. If the application is not granted, the man's position will be the same as that described above in the case of him who decides to "wait and see"; if exemption is granted it will mean that the Professional Committee considers that the man's services are urgently required by the community in which he practises, or that his circumstances are such as to lead to excessive hardship to him or his dependants. It must be remembered that the exemption may in any case be absolute, conditional, or temporary.

Thus the man who is unenrolled on June 24th puts himself, the Local Tribunal, and the Professional Committees to much trouble; he runs the risk of being taken for combatant service; if taken, he will serve for the duration of the war; and, if given a commission in the R.A.M.C., he will be paid at a lower rate than the present temporary lieutenant. Whereas the enrolled man will have his case decided by the same Committee with just the same amount of care and consideration; he will have the same right of appearing before the Committee; if selected for service, his term of service may be for one year only unless the need for a subsequent term arises, and his scale of pay will be the same as that of the temporary lieutenant under the voluntary system. Under these conditions, it would hardly seem worth while for any medical man of military age to remain unenrolled after June 24th next.

SCOTTISH AND ENGLISH SKULLS.

THE more we dig into the physical characters of the English, Scottish, Welsh, and Irish peoples, the more do anthropologists become convinced that all four nationalities are compounded out of exactly the same racial stocks of mankind. No more convincing proof of the truth of this statement has come to hand than the lengthy, elaborate, and somewhat severely mathematical monograph recently published by Dr. Matthew Young, Senior Demonstrator of Anatomy in the University of Glasgow.¹

For the first time Dr. Young has given us an accurate picture of the head-form of the million people who live on the banks of the Clyde. He had an ample supply of material, some 700 skulls, derived from a disused Glasgow graveyard. We have knowledge of only one other extensive series of British skulls, that found in a disused cemetery in the East End of London, which was investigated and described by Dr. W. R. Macdonell some twelve years ago.² A Glasgow man does not expect to discover that the Whitechapel man is his cousin, and probably no one was more surprised than the Scottish demonstrator of anatomy to discover that his "Scottish skulls presented an exceedingly close resemblance in their general form to the series of skulls described by Macdonell and known as the Whitechapel English crania, which the latter regards as the typical skull of the Londoner of 200 years ago." We have only to compare

¹ A Contribution to the Study of the Scottish Skull. *Trans. Roy. Soc. Edin.* 1916. Vol. II, Part II, pp. 347-544; 3 plates, with numerous tables of statistics. (Price 14s. 6d.)

² *Biometrika*, 1904, vol. III, p. 191.

the chief measurements to see how close the resemblance is. The mean length of the Glasgow man's skull is 187.5 mm.; the Whitechapel skull is 1.5 mm. longer; the Glasgow width, 139.5 mm.; the Whitechapel, 1.1 mm. more; the proportion of width to length (cephalic index) is exactly the same in both—namely, 74.3; the height of the Glasgow skull, 132.7 mm.; the Whitechapel has slightly a lower roof—namely, 0.7 mm. less. We are rather surprised to find the brain capacity rather smaller in the Glasgow than in the Whitechapel man—1,459.4 c.cm. in the first, against 1,476 c.cm. in the second. On the other hand, Dr. Young credits the Glasgow woman with a larger brain than her Whitechapel sister. There is reason to believe that Dr. Young has not done the brain capacity of his townsmen full justice. In the 700 skulls he found 405 which were probably male and only 100 which were probably female. We expect an equal representation of the two sexes in a burial ground. It is very likely that female skulls were included in the large male group, and seeing that, on the average, the brain capacity is about 170 c.cm. less in the woman than in the man, the inclusion of female skulls in the male group would lower the male average. When we take this circumstance into account, we may safely predict that the Glasgow-Whitechapel men have been endowed with almost the same size of brain.

The casual critic might seek to explain the resemblance between the head-form of the Glasgow and Whitechapel people on the grounds that both are living under the same conditions of town life, and that such conditions will tend to produce the same head-form. Dr. Young has convincing evidence to show that head-form is permanent under the most diverse conditions of British life. In the long barrows of England, and in the corresponding graves in Scotland, occur the remains of the people who lived in Britain some 4,000 to 5,000 years ago. In dimensions and in shape the Glasgow and Whitechapel men reproduce the head-form of these ancient British people to a surprising degree. Neolithic blood runs strong in modern people living on the banks of the Thames and Clyde. Sometime ago Professor Keith called attention in these pages to the close resemblance between the skull of Robert Burns and those of the Neolithic people which Professor Bryce had unearthed in the cairns of Arran.

But what of the Anglo-Saxon invasion and the coming of the Norseman? Dr. Young has grasped that problem too. The Scandinavian and Anglo-Saxon skulls are the same as the long barrow skull—the same type as the modern British skull; those invaders brought no new skull form to England; they were of the same stock as the ancient British. Unhappily, so we think, Dr. Young applies to those Scandinavian and West German people the name "Teutonic." In its modern usage, "Teutonic" means German, and the vast majority of modern Germans have a totally different head-form from the ancient and modern British, and the modern German is emphatically brachycephalic.

We are surprised to find that there was such a small proportion of round-headed or brachycephalic people in Dr. Young's Glasgow series. There is evidence that about 1700 years B.C. round-headed invaders, with a head-form of much the modern German type, began to land along our eastern coasts, from Caithness in the north to the Isle of Wight in the south. Their remains are found in the round barrows or in short cists in all of our eastern counties; they invaded Wales, and they reached Ireland in very considerable numbers. The late Sir

William Turner collected skulls from all parts of Scotland; out of a collection of 174 skulls, 35 (20 per cent.) were emphatically brachycephalic. There is very little trace of this brachycephalic element in either the Glasgow or the Whitechapel series of skulls.

The essential fact remains that, as regards race, the people of Whitechapel and of Glasgow are the same. There is every reason to suppose that when Dr. Young's colleagues in Cork, Dublin, Belfast, Cardiff, Bristol, Birmingham, Manchester, Liverpool, Newcastle, Edinburgh, and Aberdeen do for those cities what he has done for Glasgow the result will be approximately the same—a demonstration that we British are, as regards physical characters, a homogeneous race. We hope, however, that when these new investigations are undertaken the anatomist will remember he must be rather more than a mathematician. Dr. Young has treated the Glasgow skull as if it were a problem in Euclid. The skull is part of an elaborate machine; to be studied profitably it has to be viewed, not only with the eye of the mathematician, but also with that of the engineer, and, above all, by that of the medical man.

THE TRADE EDUCATION OF MAIMED SOLDIERS.

THE *Journal de Médecine de Bordeaux* in its May number gives an account of the School of Re-education and the various organizations for the assistance of mutilated soldiers established at Bordeaux. The work was started a year ago by the Mayor; the city gave 40,000 francs, the general council of the Gironde 20,000 francs, and the Chamber of Commerce 10,000 francs, and the State will ultimately take upon itself all the working expenses. The school is established in the extensive buildings of what was formerly the Grand Séminaire in the Rue du Hamel. There the maimed soldiers are lodged, and workshops have been arranged where masters teach them the trades they have selected. An orthopaedic hospital will be established in another building. The work is under the direction of foremen, some of whom are themselves maimed. The results are very satisfactory, but experience has shown that maimed men are seldom able to get employment in large workshops, where their inferiority in output shows up too acutely in comparison with that of their whole-limbed mates. A proposal has been made that, in view of the increasing number to be provided for, an attempt should be made to establish workshops in which only maimed men are employed. It has also been found necessary to classify the men, and for this purpose two other organizations have been created at Bordeaux, which supplement the work of the municipal school. One of these, the "Guide du Réformé," particularly occupies itself with men who have lost their lower limbs; they are placed with employers, and allowances of varying amount are given them during their apprenticeship. Allowances are also granted to some pensioners of the school, to be applied to the support of their families during their re-education. When the apprenticeship is finished the man seeks to settle in his native place or elsewhere; if he has no resources, as is often the case, L'oeuvre de l'Assistance aux mutilés pauvres, which has its head quarters in Paris, advances him the money necessary to buy tools and material up to £20. The Bordeaux school is chiefly intended for those who have lost the upper limb or the use of it. To determine the class of work for which each man is fitted a laboratory has been established in which, on admission, all men are examined; by an adaptation of Marcy's graphic method of registration on smoked cylinders the value of the stumps or paralysed limbs in regard to work is determined. By clinical examination

it is seen whether they are suited for work requiring strength or something less arduous, such as plastic arts or bookbinding. To this end pneumograms and cardiograms are taken in a state of rest and after work. By other experiments the number of calories used during work is ascertained and the degree of fatigue measured. By comparing their own tracings with those of the foremen the men can see the object aimed at. Progress is tested by weekly examinations. The director of the laboratory, Dr. Gourdon, sums up the functions of the laboratory as follows: A clinical study of the mutilated man from the working point of view, medical and scientific supervision during re-education, exact control of the work, minute research as to the best conditions of this work, adaptation of the prosthetic apparatus to the work the man is to do, and rational progressive training with the object of better utilization of stumps of paralysed limbs. The school is thus an institution for the scientific study of re-education and for the training of masters and instructors who will in turn train other maimed men and organize workshops.

THE MAKING AND FITTING OF ARTIFICIAL LIMBS.

Like the British soldier, the French soldier who has lost a limb in the war has a right to an artificial substitute. A central medical committee comprising some orthopaedic surgeons appointed some time ago by the Under Secretary of State to supervise the work, has settled on an appropriate type of apparatus for various amputations, and samples have been supplied to the manufacturers of each region, who are required strictly to adhere to the approved type in each instance. The materials to be used in the manufacture of an artificial limb must be sent to the central prosthetic laboratory at the Conservatoire des Arts et Métiers, where, under the direction of Professor Amar, they are thoroughly tested. When the apparatus is finished it is sent to the regional orthopaedic centre and is accepted definitively only when the members of a local committee have decided that it fits the man perfectly and fulfils the required conditions. The choice of apparatus is not hampered by questions of expense but is based entirely on the highest attainable standard of usefulness to the wounded men in view of the calling which they will pursue. Thus to an agricultural labourer there will be given an articulated stump solid enough to allow him to do rough work on the land, whilst to a worker in an office an artificial leg will be supplied. In not a few instances skilful and ingenious artificers have been found among the wounded themselves, but to complete the organization of the service specialist craftsmen have been brought back from the armies. In the Paris region the arrangements are now in full working order, and every Thursday 150 to 200 specimens of apparatus are examined at the hospital of the Maison Blanche by the competent committee and sent out to those for whom they are intended. In this country the arrangements differ in detail but work out to the same end; that is to say, a sailor or soldier who has lost an arm or a leg is supplied from public funds with an artificial limb made and adjusted under the supervision of surgeons specially skilled in such matters. As our readers are aware, the Queen Mary Auxiliary Hospital at Roehampton, which now has over 300 beds, has been carrying on this work for a year. Early this year a movement to establish a hospital on similar lines for Scottish soldiers was set on foot mainly through the exertions of Sir William Macewen, and the Committee is now in possession of a house and extensive grounds in the neighbourhood of Glasgow. At Brighton 500 beds have been provided in the Pavilion Military Hospital, where men who after amputation suffer from some condition of the stump which does not allow the proper fitting of an artificial limb can be treated by operation or otherwise. When ready to be fitted the man will be transferred to the hospital at Roehampton. The British and the Scottish

hospitals are independent of each other, but both have the approval and support of the Directors-General of the Royal Naval and of the Army Medical Services. It will be remembered that last March the War Office issued a *Memorandum on Amputations and Amputation Stumps*, founded on the experience gained at Roehampton, for the guidance of surgeons of military hospitals abroad and at home in the selection of the site of amputation, when choice is possible, and in the fashioning of stumps. It was reviewed in our columns on April 8th, p. 534.

THE RATIONALE AND PRACTICE OF CHEMIO-THERAPY.

THE addition of an efficient drug to the pharmacopoeia will always be an achievement of importance, and lately Mr. J. E. R. McDonagh claims to have discovered two such remedies in intramine and ferrivine.¹ From the formulae which are given the compounds appear to be orthodiaminophenyldisulphide and the iron salt of sulphanic acid respectively, both well-defined substances long known to the chemist. Mr. McDonagh claims that these compounds surpass salvarsan in value in the treatment of syphilis and have the merit of being non-toxic. Ferrivine is employed in the acute stages and intramine in chronic cases, but the best results appear to follow when they are used in conjunction. Such refractory conditions as degenerative encephalitis and interstitial keratitis are described as yielding to intramine; but from remarks made by Mr. McDonagh at the adjourned discussion in the Dermatological Section of the Royal Society of Medicine reported this week it seems that this effect is not always attained in keratitis, and the opinion has been expressed that, while in some cases of early syphilis ferrivine acts better than salvarsan, in others it is less efficient. Such is the broad outline of the practice. The *rationale* is based upon highly-involved considerations regarding oxidation and reduction processes in the living body and the effects of the size of lipid-globulin molecules and of their stereochemical configuration on adsorption and so on. The majority of experienced clinicians do not profess to be expert biochemists, and the executive of the section wisely invited the participation of scientific workers of acknowledged repute in those fields from which Mr. McDonagh has gathered his inspirations. In the consideration of the theoretical side of the subject the comments of Professor Bayliss must carry great weight, and from them—and he is not alone in his views—it seems clear that Mr. McDonagh's speculations are for the most part without experimental basis, and in certain instances mutually contradictory or actually contrary to observed facts, as when he attributes the phenomena of adsorption to active oxygen. Though Mr. McDonagh's arguments do not seem to commend themselves to authorities well versed in the nature of the problems under consideration, a discovery of practical value will atone for much inconclusive theory; it remains, therefore, to inquire what clinical evidence has been adduced. Independent observation has confirmed the occurrence of rapid improvement in the primary sore and related lymphangitis and lymphadenitis in a series of cases treated with ferrivine under Mr. McDonagh's own care, and very marked improvement was reported in about half of a series of cases treated with the remedies at the Female Lock Hospital. On the other hand, Lieutenant-Colonel Harrison and Mr. Mills, who themselves treated cases with ferrivine obtained from the makers, found that no clinical improvement followed, either when the drug was used by itself or in conjunction with intramine; the specific spirochaete also persisted in the secondary lesions for over a week after the commencement of treatment, although a single dose of salvarsan subsequently banished the parasites in eighteen hours. Dr. Sequeira's experience with ferrivine likewise led him to the conclusion

¹ BRITISH MEDICAL JOURNAL, April 22nd, p. 591.

that its effect on the secondary stage was not comparable with that of salvarsan. These speakers insisted on the very severe shock which may follow even moderate doses of ferrivine. As regards intramine, no independent evidence concerning its effect in interstitial keratitis and general paralysis appears to have been offered so far; there is practical unanimity, however, that intramuscular injections cause such severe pain as would prohibit its use in many cases, and frequently it appears to be very imperfectly absorbed. Having regard to the observed immediate effects in some cases it seems hazardous to speak of ferrivine and intramine as non-toxic. Mr. McDonagh, in closing the discussion, admitted that his drugs were capable of improvement, and claimed that he had already overcome certain disadvantages. It is evident, however, that an extended probationary period will be required for them. In the meantime we would once again utter a caution against exaggerated optimism; any reasonably safe therapeutic procedure will in this country secure an unbiased trial, especially if there is sound experimental evidence in its favour.

THE POISON APPARATUS OF THE STING RAY.

At a recent meeting of the Zoological Society of London Major H. M. Evans, M.D., R.A.M.C., read a paper on the poison organ of the sting ray (*Trygon pastinaca*). It had, he said, been observed for centuries that the wounds produced by the serrated spine growing from the base of the whip-like tail of the sting ray produced very severe injuries and pain and inflammation, which could not be accounted for by the laceration of the wounds alone. Dr. Antonio Porta, in 1905, described a gland in the groove lying medially to the rows of teeth on either side; he stated that it was similar to the gland found in *Scorpaena*. Major Evans's researches had not confirmed Porta's description in all particulars. The examination of a series of sections showed a gland of a different type from that found in the weevers, *Scorpaena*, etc. He emphasized the following points: (1) The origin of the gland from a special epithelial structure at the base of the spine; (2) the arrangement of follicles discharging their secretion by ducts or canals, communicating with the exterior by means of nipples or filaments; (3) the arrangement of these nipples at the base of the teeth; (4) the presence of muscular fibres surrounding the main canals which are instrumental in discharging the venom.

THE BATTLEFIELDS OF EAST PRUSSIA.

PROFESSOR KIRCHNER, who as a member of the Commission sent to East Prussia after the first, and again after the second Russian invasion, had exceptional opportunities for studying the effects of modern warfare, has published an account of his experiences. On August 20th, 1914, the population was notified that the province must be evacuated. Many thousands streamed away and were cared for by the war organizations. Between August 26th and 28th Hindenburg's victory temporarily eased the pressure of the Russian armies, and the civil medical administration was set the task of restoring order to the ravaged province. Professor Kirchner found the conditions less serious than he expected. Alarmist rumours had spread through the press to the effect that at the battle of Tannenberg thousands of Russians had perished in the Masurian lakes. It was feared that all the drowned men and horses would poison the province. But, as a matter of fact, the lakes are far from Tannenberg, and no foundation for these rumours could be discovered. On the whole, there was little disorganization from the sanitary point of view. The dead had been properly buried, and even on the battlefields there was little trace of the recent past. The wells were in good condition, and the land was again being ploughed. The sum of 20,000 marks was provided for the care of infants and the tuberculous; temporary hospitals were run up in place of those that had

been destroyed; 200 beds, with bedding, were supplied in a few days by the Red Cross; and the requisite number of doctors and chemists was also provided. But in October fresh Russian forces swept over the border, and the province had again to be evacuated. This time the Russians stayed longer, and devastated the country more thoroughly. When Professor Kirchner and his Commission returned to the province after the second Russian retreat, the country was ruined. It was estimated that 300 million marks would be required to restore the 36,000 houses which had been burnt. Russian prisoners were employed by the thousand in gangs of thirty to forty for three months. Trenches were filled up, wells were cleaned, and hospitals and other most necessary buildings were restored. The graves of the fallen were also attended to. By July, 1915, some 75 per cent. of the inhabitants had returned, but for lack of housing accommodation a considerable degree of overcrowding was unavoidable. Though great efforts were being made to restore the province, Professor Kirchner foresaw that the ravages of the war would take long to repair.

THE BELGIAN ATROCITIES.

WE may be permitted here to make reference to a Birthday honour not mentioned among those enumerated elsewhere. The editor of the *Field* went out of his own line of country to publish in February, 1915, a special supplement containing a report by Dr. Arthur Tacquin, one of the physicians-in-ordinary to the King of the Belgians. It was copiously illustrated; it did not show all the crimes against our common human nature committed by the Germans in Belgium. It would have needed a cinematograph and the result might not have been edifying, but it contained a sufficient number of photographs to prove the depth of the fuddleheadedness which caused them to destroy the whole machinery of communal life in many parts of what they then regarded and still profess to regard as a conquered province. The great merit of the publication was that it foresaw and answered by anticipation the excuses the Germans would make if they failed as they have failed, though they are not yet beaten. The nature of the excuses is illustrated by a letter received by Professor H. A. Lorentz, the eminent physicist of Haarlem, from Dr. Max Planck, professor of physics in the University of Berlin. Sir Oliver Lodge sent a translation to the *Times* of June 5th. It began by the statement that "The well-known appeal to the world of culture which was signed by 93 German scholars and artists, and published in August, 1914, has, owing to the terms in which it was drawn up, led to mistaken conceptions as to the attitude of the signatories." Professor Planck says that the "appeal, which reflects in its composition the patriotic excitement of the first weeks of war, was intended to signify and could signify nothing but an act of defence—above all, of protection of the German army against the bitter accusations brought against it." After stating the obvious fact that scholars and artists of Germany cannot be responsible for every single action of every German, he goes on to say that "we are not as yet in a position to pass a final judgement in any scientific sense of the term on the great questions of the history of the present day. Only a subsequent, many-sided, and objective examination can decide in which quarters will be finally fixed the primary responsibility for the failure of the efforts for peace and for all the human suffering which has been caused—an examination whose results we await with a quiet conscience." Dr. Planck, it will be seen, avoids any attempt to consider the evidence of the atrocious manner in which the German army wars upon civil populations. It has been set out in official publications which have not and cannot be gainsaid, and Sir Theodore Cook's particular service, in the two supplements of the *Field*—that to which we have already

referred and another published this year—has been to put some of the facts in an objective form before the large public which does not read official documents.

MILITARY HOSPITAL GAZETTES.

We have referred from time to time to periodicals issued by military hospitals in Great Britain. We have now received a copy of what we believe to be the first publication of this kind issued by a hospital with the British Expeditionary Force in France. It is entitled, *Behind the Lines*, and comes to us from the officer commanding the stationary hospital by which it is issued. The editor, in a preface, says that it is intended primarily to form a common bond of interest and information among the members of the unit, and at the same time "to brighten the lives of the patients within the walls of our historic building." The first article, by an officer who has been with the unit from the beginning, gives a sketch of its history from the evening of August 4th, 1914, when orders were received to mobilize. On August 7th the work of drawing the equipment (which weighed some 30 tons) and loading it on to a train was begun, and by August 9th the unit was ready to move. It actually left on August 14th, and disembarked in France on the following day. The first piece of work it was given was to organize rest stations along the line of evacuation, and its services in that capacity were very useful in the early days of the campaign when from necessity large numbers of the wounded had to be removed in improvised trains. In September the unit, through the courtesy of the French authorities, obtained possession of a very fine building as a hospital, and within a day or two was actually engaged in hospital work. A month later, however, it had to move again, and in its new home received a large number of wounded from the battle of Ypres. Where the hospital is now does not appear, but thanks are expressed to Captain Marescaux of the French Army Engineers for helping to get a rambling old building into order. The oldest of the home periodicals of this class, the *Craigleith Hospital Chronicle*, continues its cheerful way, but it has compressed its May and June numbers into one. We note in it an appeal from the Propaganda Bureau, 3, Rue François 1^{er}, Paris, established under the auspices of the Ministry for Foreign Affairs, for contributions to an exhibition which it is getting up of trench magazines. The original notion appears to have been to collect such magazines from the French army only, but the appeal continues, "now that the fellowship of the allied nations and of their armies is being asserted more firmly than ever, we think it would be useful to show that all the soldiers of the Entente are equally filled with that spirit of humour, fun, and cheerfulness which is so fitting an accompaniment to their display of heroism, and testifies to their unconquerable hopes." Editors of such periodicals may be asked to remember also that the library of the British Medical Association is forming a collection, and that Dr. W. W. Keen of Philadelphia is doing the same for the great library of the College of Physicians in that city. The *Gazette of the 3rd London General Hospital* has issued two numbers since we mentioned it last. It continues to be remarkable for the excellence of its caricatures. Two which will appeal to many are drawings of a dog in the hospital, one as seen by its fond mistress, and the other as seen by a jaundiced world. To the June number Mr. Nevinson contributes one of his admirable cubist drawings, "At the Concert," but to get the smile on the faces of the audience he is compelled to resort to curves. The *Norfolk War Hospital Magazine* has reached its third number; it also mixes grave with gay, and has some clever drawings, including some thumb-nail sketches of surgeons and nurses in an operating theatre. We have also seen a copy of the *Brigade Revue*, issued by the 2/1st South Wales Mounted Brigade, which seems to be almost

entirely frivolous. It is not medical, although we believe the medical officers have something to do with it. The best thing in it is a piece of advice: "Fear no man! Do right! Fear all women! Don't write."

IMPORTED SYNTHETIC DRUGS.

THE JOURNAL this week publishes an advertisement of somewhat unusual character, issued by the firm of W. Martindale, manufacturing chemists. It appeals to the medical profession to recognize the necessity of supporting British chemical industry. It is stated that even now a very large proportion of organic chemicals in demand are being imported instead of being made at home. The opinion is expressed that without assistance and incentive to the home trade from the Government and the medical profession, there will be a reversion at the end of the war to conditions very similar to those which existed before it broke out. The Council of the British Medical Association, in its annual report,¹ expressed the view that the country and the profession cannot afford again to be left at the mercy of a foreign supply of substances many of which are essential in medical and surgical treatment. The Council has accordingly asked the Government to consider the advisability of assisting British manufacturing chemists to produce the necessary drugs and chemicals heretofore imported from Germany. There can be no doubt that the medical profession can exercise great influence if it keeps the point constantly in mind. Not a few of the substances which have been exploited by German advertisements under fancy names are of known chemical constitution, and can be made by any competent manufacturing chemist, but the chemists say that they cannot be expected to lay down plant to manufacture drugs and chemicals unless they have some reasonable prospect of receiving sufficient support to ensure them against eventual loss. The amount of money which used to go out of the country to Germany for organic and synthetic chemicals, many of them of very questionable value, was very large, and the demand was in a great part due to the success with the medical profession of the German advertising propaganda.

BENEVOLENT FUND FOR THE R.A.M.C., TERRITORIAL, SPECIAL RESERVE, AND NEW ARMIES.

ABOUT 100 officers attended the meeting held at the R.A.M. College on June 1st to consider the advisability of establishing, for the benefit of officers, non-commissioned officers, and men, of the Territorial, Special Reserve, and new armies, some kind of benevolent organization similar to that which exists in the Regular Royal Army Medical Corps. The Director-General, Sir Alfred Keogh, who was in the chair, explained the various benevolent funds which exist in the R.A.M.C. (Regulars). After some discussion, during which Dr. West pointed out that the dangers of overlapping with the British Medical Benevolent Fund must be avoided, it was unanimously agreed that it would be of the greatest advantage to start a benevolent fund for the auxiliary branches of the R.A.M.C., and a provisional committee of eight officers representing each of the three branches was appointed. This committee was directed to inquire into the whole matter, and to report to a general meeting of officers to be held towards the end of June. Sir Alfred Keogh was warmly thanked for the interest he took in the welfare of the members of the medical services of the army, and a vote of thanks to him brought the meeting to a close.

With the current number of the *British Dental Journal* there is published a war supplement on the treatment in Germany of gunshot injuries of the face and jaws. In preparing this supplement Mr. Dolamore has read and extracted practically the whole German literature on the

¹ SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL, May 6th, 1916, page 97.

subject since the Russo-Japanese and Balkan wars. Splinting and reparative apparatus in the main resemble those in general use. Of special interest are the notes on the use of sunlight and cupping glasses in promoting healing, the description of plastic and bone-implanting operations, and a summary of the histological and clinical laws of implantation. The supplement contains 80 well-written pages, with 88 excellent illustrations. It has been printed also as a separate pamphlet, which can be obtained at the British Dental Association Offices, 19, Hanover Square, at a cost to non-members of 5s.

By a recent decree of the Italian Government all medical practitioners up to the age of 46 have been called up for military service.

Medical Notes in Parliament.

Compulsory Military Service.

UNDER the new Military Service Act every British subject ordinarily resident in Great Britain who, for the time being, has attained the age of 18 and has not attained the age of 41 before the appointed date (June 24th, 1916) is liable for military service for the period of the war, but as far as possible men are not to be sent to serve abroad before they attain the age of 19. For the purpose of comparing the position in other countries with that which will exist in this country after June 24th, it will be interesting to reproduce information given by Mr. Tennant to Mr. W. Thorne on May 16th, in a written answer:

In Germany military service commences on the 17th birthday and terminates on the 45th. Active military service does not commence before the 20th birthday (in peace).

In Austria it begins on the 18th birthday and terminates on the 42nd birthday. Austrians are now being called up to the age of 55. Active military service commences from January 1st of the year in which the 21st birthday occurs.

In France military service commences in the year following the 19th birthday and terminates twenty-eight years from October 1st of the year following that in which the 19th birthday occurs.

In Belgium military service commences on the 18th birthday, and terminates in peace time on the 33rd birthday. Those between 18 and 25 in addition to those serving on March 1st, 1915, must serve for the duration of the war.

In Italy military service begins on the 20th birthday, and terminates on the 39th birthday.

In Russia military service begins in the October following the year in which the 20th birthday has occurred, and ends on the 43rd birthday.

In Serbia and Montenegro military service commences on the 18th birthday, and terminates on the 50th and 62nd birthdays respectively.

In Turkey military service commences on March 1st following the 20th birthday and terminates twenty-five years subsequently.

In Japan military service commences on the 17th birthday, and ends on the 39th birthday. The men are not called up for actual service till 20 years of age, but may enlist between the ages of 17 and 20.

No claim for discharge holds good in war time in the cases of Germany, Russia, Austria, and France, even if the age limits specified for those countries have been reached. In war time Austrian and German conscripts are called on for active service at any time after their 17th birthday.

War.

Dardanelles and Mesopotamia.—On May 31st Mr. Shirley Benn asked the name of the chief medical officer with the Expeditionary Force at the Dardanelles, and also the name of the medical officer who had the responsibility in regard to medical provision for the expedition to Mesopotamia. Mr. Tennant replied as follows: "The Director of Medical Services of the Expeditionary Force at the Dardanelles was, first, Surgeon-General Birrell, and, later, Surgeon-General Bedford. The arrangements for the Mesopotamian expedition were made by the Government of India, and Surgeon-General Hathaway was the Director of Medical Services of the Force. Surgeon-General Sir W. Babbie was Director of Medical Services in India at the time."

Inoculation.—On June 1st Major Guinness asked whether, when inoculating troops against typhoid and cholera, certain officers R.A.M.C. did not sterilize their

hypodermic needles between individual inoculations, relying solely on the sterilization of the skin. Mr. Tennant said that he was not aware that this happened. Instructions had been, and were now, issued with all consignments of antityphoid vaccine emphasizing the importance of sterilizing the needle after each injection, and this was understood to be the routine practice with all injections. If evidence were produced that these instructions were in some instances not being followed, all commands would be informed.

Artificial Limbs.—In reply to a question by Mr. Barnes, who appeared to be under the impression that sailors and soldiers who had lost a limb or limbs were dependent upon charity for the supply of artificial limbs, the Financial Secretary to the Admiralty said, on May 31st, that all artificial limbs for sailors and soldiers rendered necessary by injuries received on service were supplied in the first place, and subsequently repairs carried out or replacement when necessary made, at the expense of Admiralty, War Office, or Greenwich Hospital funds. The particular class of limb fitted was decided on by skilled orthopaedic surgeons, bearing in mind the man's probable future employment. No sailors or soldiers were dependent on charity for such appliances.

Food Parcels to Germany.—Mr. Tennant stated on June 1st that there was reason to believe that the supply of parcels to prisoners of war in Germany would be more efficiently carried out if the efforts of the numerous organizations which have taken up this work were properly co-ordinated; steps had already been taken to effect this. In a written reply, on the same day, Mr. Tennant said that he believed that the great majority of parcels properly packed and addressed reached British prisoners in Germany, but it was impossible to state any percentage.

Small-pox and Vaccination.—In a written reply, on June 1st, Mr. Tennant said that orders curtailing soldiers' leave on account of small-pox outbreaks in the counties of Lancashire, Northumberland, Durham, Glamorgan, and Monmouth, had been in force, but had now been withdrawn, except in the case of three towns where cases of small-pox had recently occurred. The restrictions would not be enforced in regard to men who had been recently successfully vaccinated.

Motor-car Duties.—Mr. Wason asked the Chancellor of the Exchequer on May 31st whether he proposed to differentiate between low-priced cars practically only used for trade purposes and cars built and used privately for pleasure; and whether, in view of the ever increasing scarcity of petrol, the time had not arrived when no one should be allowed to use a private motor without a permit from the Government. Mr. McKenna replied that cars used for trade purposes were, under existing law, more favourably treated than pleasure cars, provided they were constructed and adapted for trade purposes. He did not think it would be possible in practice to make the concession depend solely upon use apart from construction, as the opportunities for evasion would obviously be very great. In a written reply, on the same day, Mr. McKenna said that he was considering whether exemption from duty could not be granted for cars used exclusively by officers of the Volunteer Training Corps in the execution of their military duties while called up in protection companies on the lines of communication in England, but he did not think it would be practicable to make any concession in respect of cars used partly for such purposes and partly for other purposes.

Milk Supply of London.—The Parliamentary Secretary to the Board of Trade has stated, in reply to various questions, that at a conference he had had with representatives of the London milk trade, they alleged that the prices the London purveyors were paying were from 5d. to 6d. a gallon more than pre-war prices. The rise was partly due to increased cost of distribution, but mainly to the high price of all agricultural produce, and particularly of meat and cheese. If farmers could not obtain anything like a proportionate price for milk there was a tendency to sell cows and heifers to the butcher, and this was accentuated by the withdrawal of milkers for military purposes. If, owing to disproportion of price, the production of milk were reduced, a shortage of milk would follow, which would have more serious consequences than the rise in price. There was no evidence of any shortage of supply at present. It was not easy to compel men to carry on business which did not bring in a reasonable profit, and he believed that in the long run the best way of keeping up the milk supply was to pay a price which would yield to the producer a fair return for the increased cost of labour, feeding stuffs, and cows, and not less remunerative conditions than other branches of agriculture. The increase in the contract price as compared with the rates prior to the outbreak of war represented the larger part of the increase in the retail price in London.

THE WAR.

MEDICAL ADVISORY BOARD IN FRANCE.

THE British Force in France has been steadily growing, and as the medical department has not been unaffected certain primary and secondary results are worth attention here. Among primary results are an increase both in the number of medical units and the total medical personnel; apart from additional battalion medical officers, new field ambulances have arrived, new casualty clearing stations have had to be created, more motor ambulance convoys and hospital trains provided, fresh convalescent camps started, new mobile laboratories set to work, further sanitary sections formed, extra advanced medical dépôts opened, and the number of hospital beds increased either by the extension of existing stationary and general hospitals, or the addition of new corresponding units.

Among the secondary results has been an increase in the number of civilian medical men of distinction appointed to act as consultants to the British forces in France. In the first stage of the war, when the British army was represented in France solely by the original Expeditionary Force, there were only two consultants. By the end of 1914 the two had grown to half a dozen, and there are now about fifteen or sixteen, if all those who do work of a consultant order be included in the count. Of the total number, one is attached to each of the field armies, his primary duty being to supervise the professional work of the casualty-clearing stations in his area; two are attached to general head quarters; and the rest fulfil the needs of the various hospital bases.

A further interesting development is the result less of the growth of the army as a whole than of the great increase in the area that it now covers.

Very soon after he arrived in France to take personal charge of the medical affairs of the army, Sir Arthur Sloggett converted his principal officers and such consultants as had then been appointed into a kind of council, and this council, which grew with the number of consultants, he has ever since periodically summoned to meet for the discussion of current questions. But when the first extension of the British army zone took place, it became more difficult to bring together those who would naturally be present, and now that the area has been still further extended, the distances that have to be covered are so considerable that the occasions upon which all members will be able to leave their ordinary work for the time being to attend the meeting are likely to be increasingly rare.

In consequence of this the Director-General has recently supplemented his advisory board by a kind of inner council consisting of members on whose presence he can always depend. Its constitution is as follows:

Chairman: The Director-General, Surgeon-General Sir A. T. Sloggett, K.C.B., C.M.G., K.H.S.

Vice-Chairman: Surgeon-General T. B. Woodhouse, C.B.

Members:

Surgeon-General Sir G. H. Makins, K.C.M.G., C.B., F.R.C.S.

Surgeon-General Sir A. A. Bowlby, K.C.M.G., K.C.V.O., F.R.C.S.

Colonel Sir Wilmot Herringham, C.B., M.D., F.R.C.P.

Colonel Sir J. R. Bradford, K.C.M.G., C.B., F.R.S., M.D., F.R.C.P.

Colonel Sir W. B. Leishman, C.B., F.R.S., M.B., F.R.C.P., K.H.P.

Lieutenant-Colonel W. W. O. Beveridge, C.B., D.S.O., M.B.

If this list be analysed, it will be found that the permanent and temporary medical officers of the army—or, in other words, the military and civilian elements of the present medical service—are represented in exactly equal proportions. The first two and last two are permanent officers, the middle four civilian consultants holding temporary rank.

It will also be found that the same equality of representation appertains to the four great divisions of medicine in the field—Administrative medicine by Sir Arthur Sloggett and General Woodhouse; surgery by Sir George Makins and Sir Anthony Bowlby; clinical medicine by Sir Wilmot Herringham and Sir John Rose Bradford; preventive medicine by Sir William Leishman and Lieutenant-Colonel Beveridge.

On still more minute analysis some other points of interest emerge. Thus, general administration and base administration may be taken to be represented by the chairman and General Woodhouse respectively, the latter being D.M.S. on the lines of communication; front line surgery, by Sir Anthony Bowlby, who has served with the field army ever since his arrival in France about September, 1914; base surgery, by Sir George Makins, who came out at the same time as Sir Anthony Bowlby, but took to base hospital work as soon as the Flanders front was formed; front line medicine by Sir Wilmot Herringham, who has been serving with the field armies for the past fifteen or sixteen months; base medicine, by Sir J. R. Bradford, who came out about the same time, but has been engaged throughout in base hospital areas; and the bacteriological and hygiene sides of preventive medicine are represented by Sir William Leishman and Colonel Beveridge respectively.

It is clear, therefore, that the constitution of this board must have been very carefully thought out, while its professional strength is very noteworthy.

NERVOUS AND MENTAL SHOCK.

We are indebted to Lieutenant-Colonel William Aldren Turner, M.D., R.A.M.C.(temp.), F.R.C.P., Physician to King's College Hospital and to the National Hospital for the Paralysed and Epileptic, London, for the following account of the arrangements for the care of cases of nervous and mental shock among soldiers coming from overseas:

Cases of nervous and mental breakdown due to shock, fatigue, exposure, and the other conditions incidental to a campaign, began to arrive in England in September, 1914, shortly after the commencement of hostilities. The cases showed a varied symptomatology, but could be classified into three main groups. One group was recognized whose symptoms were due to the bursting of high explosive shells in the immediate vicinity of the patient or to the secondary effects of the explosion, such as burial under earth and debris or the inhalation of noxious gases. The second group included cases of a general neurasthenic character (using this term in its widest sense) attributable to exhaustion of the nervous system resulting from physical and nervous strain, sleeplessness, fear, anxiety, and harassing sights and experiences. The third group included cases of mental breakdown—the milder as well as the more severe psychoses—mental confusion, mania, melancholia, and delusional and hallucinatory psychoses.

At the commencement of the war the cases of nervous shock and neurasthenia were transferred from overseas in company with medical and surgical cases, and were treated in the general wards of the hospitals at which they arrived, while the cases of mental disorder were transferred to D block, Netley, the established institution for the treatment of mental patients in the service of the army.

As cases of nervous breakdown of all kinds were coming over in considerable numbers in consequence of the severe fighting during October and November, 1914, and as it was deemed desirable that special provision should be made for their treatment, Sir Alfred Keogh commissioned a special medical officer to proceed to France to report upon the cases—their nature and numbers and the conditions under which their treatment should be carried out to the best advantage both during the preliminary stages in France and afterwards on their arrival in this country. The general purport of the report was to the effect that the cases of nervous shock and neurasthenia should be given treatment in hospitals for nervous diseases and in special institutions provided for the purpose, under the care of physicians with special neurological knowledge. In consequence, arrangements were made whereby cases of neurasthenia and nervous breakdown were labelled on their departure from the base hospitals by medical officers with special qualifications for this work, and were transferred directly to the special hospitals and institutions provided for their treatment at home. By these means cases of functional paralysis, neurasthenia, and the milder psychoses were separated as early as possible from cases of severe mental disorder.

The special institutions were the hospitals for nervous diseases and the Red Cross Military Hospital, Maghull. This institution, which was built to meet the requirements of the Mental Deficiency Act, was handed over to the War Office in December, 1914, as it was necessary to have a hospital suitable for those "borderline" cases which

required more special supervision than could be given in hospitals. It was desirable, also, to provide an institution to which mental cases might be sent from D block, in order to obviate their transference to public asylums—a policy which was adopted in view of the special circumstances attending the cause of the disorders. The Military Hospital, Maghull, being built upon the villa pattern, provided the requirements of these cases. To meet the increasing number of cases, further institutions were added at later dates to those just mentioned, namely, the Springfield War Hospital for severe and protracted cases of neurasthenia and "borderline" cases, and the Napsbury War Hospital for cases of acute mental disorder requiring asylum care and supervision.

CLEARING HOSPITALS.

In order that all cases should receive a short period of rest and treatment on their return from France before being transferred to the most suitable institution for final disposal and treatment, two "clearing" hospitals were established early in 1915. These were:

1. *The Neurological Section, 4th London Territorial General Hospital.*—All neurological cases, labelled as such at the British base hospitals overseas, were transferred to this section. There they received a short probationary course of treatment, with the result that a large number recovered rapidly and in due course were returned for light duty. A certain number, however, were of a more serious and protracted character. These were transferred eventually to one of the hospitals provided for the purpose—namely, the Maghull or the Springfield War Hospitals. In the event of a patient becoming insane, he was transferred to D block, Netley, or to the Napsbury War Hospital.

2. *D Block, Netley.*—All cases of acute mental disorder arising in soldiers overseas were transferred to this section. After a short period for observation and discriminatory sifting, the cases were transferred, on the one hand, to Napsbury War Hospital, should they be considered of a certifiable character and to require care and treatment under asylum conditions; on the other hand, to the Maghull or Springfield War Hospitals if of a non-certifiable character but requiring more care and supervision than could be obtained in a general hospital.

NEUROLOGICAL SECTIONS.

The foregoing is a brief review of the provision for the cases of nervous and mental breakdown up to May, 1915. For some time before this date it had been noticed that a considerable number of neurological cases were coming from overseas directly into central and auxiliary military hospitals scattered throughout the country. Partly to meet the needs of these cases and partly to provide additional accommodation for the increasing number of cases, the Director-General established Neurological Sections in all the Territorial General Hospitals throughout England, Scotland, and Wales (May 24th, 1915). These sections were officered where possible by physicians specially versed in nervous diseases. The primary object of these sections was to furnish the same probationary course of treatment to the cases on arrival at the Territorial General Hospitals as was given in the clearing hospitals, and to bring in all cases from the auxiliary hospitals in which suitable or sufficient treatment was not available. Moreover, cases of a serious or protracted nature, or cases requiring supervision of a special character, could be transferred from them to the Maghull or Springfield War Hospitals.

Scotland.—With the introduction of Neurological Sections into the Scottish General Territorial Hospitals it was considered advisable that a special hospital should be provided in Scotland. Through the assistance of the Scottish Branch of the Red Cross this was forthcoming in the Royal Victoria Hospital, Edinburgh, which has continued to provide accommodation for cases of a neurological character.

Netley.—At the same time a Neurological Section was formed in the main hospital building, Netley, the chief object of which was to permit of the removal from the convoys arriving at D block from overseas all cases which the medical officers there considered did not require supervision of a special kind, as some cases had so far recovered on arrival at Netley as to be deemed suitable for treatment in a neurological rather than in a mental section.

THE DISPOSAL OF PATIENTS.

In order to understand fully the arrangements existing at the present time for the care and treatment of unwounded soldiers suffering from nervous shock, neurasthenia, and mental disorder, let us follow from overseas two or three hypothetical patients to their final destination in this country.

On arrival at one of the British base hospitals abroad,

* The term "neurological" is used here to refer to unwounded cases suffering from neurasthenia, the functional paralyses, hysteria, and the milder psychoses.

the soldier's condition is investigated by a special medical officer. The patient then is sent to a section of a hospital according as his symptoms are of a neurological or a mental character. Should he be suffering from transitory mental symptoms which subside rapidly, he is transferred from the mental to the neurological section as soon as it is advisable to do so. In order to meet this class of case special accommodation is now being provided at the base hospitals overseas, so that the patient may be placed under the most suitable circumstances for rapid recovery. The patients are labelled for transference to one of the clearing hospitals at home—if neurological, to the 4th London Territorial General Hospital, or the Neurological Section, R.V.H., Netley; if mental, to D block, Netley.

Neurological Cases.

On arrival at one of the clearing hospitals just mentioned, or at a neurological section in any Territorial General Hospital, the patient is given treatment. If his symptoms are slight or transitory and disappear rapidly, he is sent on furlough and later is returned to light duty. On the other hand, should the course of the disorder be less favourable or should symptoms develop which require special supervision, or if it is the opinion of the medical officers that the case is likely to be protracted, or to require special treatment not available in the section, the patient may be transferred to one of the special hospitals for nervous diseases or to a special institution: (a) to the Military Hospital, Maghull, for the Northern and Western Commands; (b) to the Springfield War Hospital for the Eastern, Southern, and Aldershot Commands; (c) and to the Royal Victoria Hospital, Edinburgh, for the Scottish Command. If the patient is under treatment at one of the hospitals in the Irish Command, he may be transferred to the King George V Hospital, Dublin.

If for various reasons it has not been possible to send patients home through the clearing hospitals so that they arrive directly from overseas at central or auxiliary military hospitals in which there is no neurological section, or to which no medical officer with special experience is attached, a short period of treatment is given, but should recovery not take place within two or three weeks, the patient is transferred for treatment to the neurological section of the nearest Territorial General Hospital.

From the preceding account it is evident that every case of nervous shock and neurasthenia coming from overseas is given a short period of rest and treatment in the hospital at home at which he arrives. In many instances this period is sufficient to permit of recovery. In other cases sufficient opportunity is provided to study the symptoms with a view to the transference of the patient to one of the special institutions should this further step be necessary.

Mental Cases.

On arrival from overseas at D block, Netley, the patients are examined by the special medical officers attached to the hospital. All cases which are considered to be of a neurological character are removed for treatment to the Neurological Section in the main hospital building, Netley. All patients suffering from the severer psychoses of a certifiable type are given two or three weeks' probationary treatment in D block. If no recovery has taken place during this time, they are transferred to the Napsbury War Hospital, or to the Dykebar War Hospital, Paisley, if their domicile is in Scotland, or if they belong to Scottish regiments.

No mental cases are transferred directly to Ireland, but special arrangements have been made recently by which overseas cases of mental disorder arriving in Ireland may be treated in a villa attached to the Richmond District Asylum.

The number of cases which recover during their stay in D block and are returned to light duty is negligible, but a certain number recover sufficiently during their stay there to be no longer considered as of a certifiable character. These latter are transferred to the Red Cross Military Hospital, Maghull, or the Springfield War Hospital, for further observation and treatment.

A short account may be given of the institutions to which reference has been made, the general character of the cases retained for treatment, and the percentage of cases returned to light duty.

4th London Territorial General Hospital.

The Neurological Section of the 4th London General Hospital is the largest of the Neurological Sections, and in addition to receiving the majority of the neurological cases sent home directly from overseas, it accepts patients transferred from central and auxiliary military hospitals in the London district and adjoining counties. It contains 400 beds. An important

division of the section is the Maudsley Hospital, which is especially well adapted for the care and treatment of soldiers suffering from all forms of traumatic neurasthenia, hysteria, and the milder psychoses.

Netley.

The Neurological Section of the Royal Victoria Hospital, Netley, occupies several wards in the main hospital building, and consists of about 100 beds. It serves a most useful purpose in taking over for treatment cases which have been sent from overseas to D block, but which require no longer the special supervision provided there. Cases are sent also directly to the section from overseas.

The type of case observed and treated in these sections is similar. They are: Most forms of functional paralysis, especially paraplegia, disturbances of speech and articulation, amnesia or loss of memory, the effects of terrifying dreams, mutism, deafness, deaf-mutism, amblyopia, "bent-back," tremblings and motor agitations, tic-like movements, sleeplessness, nervous debility, indecision, loss of self-confidence and the milder forms of neurasthenia, simple mental confusion, the anxiety psycho-neuroses and simple mental depression.

The treatment adopted consists chiefly of rest and feeding; massage, and electrical applications in suitable cases, baths, when these seem indicated, and psychotherapy in the form of simple suggestion and occasional hypnosis.

In a general way the results of treatment at the 4th London General Hospital show 40 per cent. of cases returned to light duty, 20 per cent. invalided, and 20 per cent. transferred for further treatment to the special institutions.

The Special Institutions.

The Red Cross Military Hospital, Maghull, and the Springfield War Hospital are constructed on somewhat similar lines in that they are provided with single rooms and special accommodation for cases requiring isolation and supervision in addition to day rooms and dormitories.

The Maghull Military Hospital had not been used for the treatment of patients before it was taken over by the War Office, but the Springfield War Hospital had been employed as a hospital for defective children for about ten years.

The available accommodation in the two hospitals amounts to about 550 beds. No case is admitted directly from overseas to either of these institutions, as all cases have received a course of treatment at one of the military hospitals at home before transference. The patients most suitable for treatment in these institutions are cases of neurasthenia of a severe or protracted character, the milder psychoses, such as simple melancholia and the anxiety psychoses, psychoses with obsessions and fears, profound amnesia, epilepsy, high grade mental defectives, the milder types of primary dementia, and all cases of a functional character which do not lend themselves to treatment in a general hospital.

Treatment is conducted upon general lines—rest, feeding, indoor and outdoor recreation, and massage in suitable cases. At the Maghull Military Hospital a form of psycho-analysis has been used with benefit in selected cases. The results of treatment at Maghull show about 40 per cent. of cases returned to light duty.

The Mental Hospitals.

Napsbury War Hospital and Dykebar War Hospital, N.B., receive the majority of their patients from D block, Netley; but Napsbury admits mental cases also from military hospitals in the Southern Command and the Midland counties; Dykebar admits also from military hospitals in the Scottish Command and the Northern counties. The Napsbury War Hospital is the hospital section of the parent asylum; Dykebar is one of the most recent of the Scottish asylums, built upon the villa pattern. The available accommodation in the two hospitals is about 700 beds.

The patients transferred to these hospitals are of a certifiable type and include most of the severe forms of acute mental disorder—the confusional psychoses, mania, the graver melancholias, acute delusional and hallucinatory psychoses, dementia praecox, mental deficiency with confusion, general paralysis of the insane, and epilepsy with mental symptoms.

In accordance with accepted policy, none of the patients in these hospitals is certified as a person of unsound mind. Each patient is given a reasonable period of treatment with a view to recovery.

In consequence, however, of the accumulation of chronic and incurable cases which was observed a few months ago, it was decided to board and discharge to asylums all cases of general paralysis of the insane, of epilepsy with insanity, and all patients who had been in asylums prior to enlistment. A certain number of chronic cases also are boarded and discharged to asylums if no improvement is recorded after a fair and reasonable period of observation and treatment.

It is obvious from the nature of the disorders that the percentage of cases returned to light duty must be small, but the figures from the Napsbury War Hospital show from 10 to 15 per cent. of cases discharged to light duty.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

In the great naval battle fought off the coast of Jutland on May 31st and June 1st we have lost six large ships and eight destroyers; 335 officers were killed, and 25 wounded officers survived. From the *Queen Mary* four officers were saved, and from the *Invincible* two; the *Indefatigable*, *Defence*, and *Black Prince* went down with all their ships' complements, while on the *Warrior* only one officer was lost. The list of officers killed includes 23 medical officers.

Killed.

H.M.S. *Queen Mary*.

Fleet Surgeon Francis F. Lobb.

Surgeons Charles W. Lewis; Maurice H. de J. Harper, M.B.

Fleet Surgeon Lobb received his medical education at St. Mary's Hospital, and took the diplomas of M.R.C.S., L.R.C.P. in 1893. He received the South African medal for services on H.M.S. *Thrush* in the Delagoa Bay blockade and the landing at Mossel Bay and Lambert's Bay. In 1901 he served with the Gambia River expedition and organized a base hospital. In that and the following year he took part in the Aro River expedition, which was for fourteen days in boats up the Lower Niger; for these services he received the general African medal with Aro clasp. As staff surgeon on the *Pegasus* in 1908 he was awarded the French marine medal for services in connexion with the wreck of the barque *Le Président Félix Faure*. In 1909 he made a report on Pitcairn Island, for which he received the thanks of the Colonial Office. He was promoted Fleet Surgeon on May 23rd, 1914.

Surgeon Lewis, the son of Professor Lewis of Capetown, graduated M.B., Ch.B. Edin. in 1914, and received his commission as temporary Surgeon R.N. on March 13th, 1915.

Surgeon Harper graduated M.B., B.S. Durham in 1914, and received his commission as temporary surgeon R.N. on September 21st, 1914.

H.M.S. *Invincible*.

Fleet Surgeon Walter J. Bearblock.

Surgeons Cyril O. H. Jones; George Shorland.

Fleet Surgeon Bearblock was educated at Guy's Hospital, and took the diplomas of M.R.C.S., L.R.C.P. Lond. in 1887. He was at one time assistant house-surgeon at the Royal Albert Hospital, Devonport. He attained the rank of Fleet Surgeon on February 21st, 1915.

Surgeon Jones was educated at St. Thomas's Hospital, where he was house-physician. He took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1915, and entered the navy as temporary Surgeon on August 17th, 1915.

Surgeon Shorland was educated at Guy's Hospital, and took the M.R.C.S. and L.R.C.P. Lond. in 1901. He was medical officer of the Railway Clearing House, Euston Square, and honorary surgeon to the Railway Benevolent Institution till he took a temporary commission as Surgeon in the navy.

H.M.S. *Indefatigable*.

Fleet Surgeon Hugh L. Norris.

Surgeons Sidney Punch; Archibald A. Morison.

Fleet Surgeon Norris was educated at St. Thomas's Hospital, and took the diplomas of M.R.C.S., L.R.C.P. in 1898. He was promoted to Fleet Surgeon on November 8th, 1914.

Surgeon Punch was educated at University College, Cork, and took the diplomas of L.R.C.P. and S.Ire. in 1912. He entered the navy as Surgeon on October 4th, 1912.

Surgeon Morison, who was 29 years of age, was the sixth son of the late Dr. Donald Morison (Bengal), and was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1912. He took the Beane prize in surgery and anatomy in 1910, had been resident surgeon at the Royal Maternity Hospital, Edinburgh, and was a fellow of the Edinburgh Obstetrical Society. He received a temporary commission as Surgeon R.N. on August 6th, 1914.

H.M.S. *Defence*.

Fleet Surgeon Frederick A. Capps.

Surgeons Frederick W. T. Clemens; G. M. Johnson, M.B.

Fleet Surgeon Capps received his medical education in Edinburgh, and took the triple Scottish qualification in 1890. He attained the rank of Fleet Surgeon on May 11th, 1903.

Surgeon Clemens was educated at the University of Bristol, and took the degrees of M.B., B.S. Lond. in 1913. He had been assistant house-surgeon to the Taunton and Somerset Hospital, and received his commission as temporary Surgeon R.N. on August 6th, 1914.

Surgeon Johnson was educated at Oxford and the London Hospital; he graduated M.B., B.Ch. Oxford in 1908, and was at one time house-surgeon and house-physician to the Radcliffe Infirmary. He received his temporary commission as Surgeon R.N. on September 28th, 1915.

H.M.S. Black Prince.

Fleet Surgeon Herbert L. Geoghegan, M.D.

Surgeons Thomas M. Wood-Robinson; John S. D. MacCormac.

Fleet Surgeon Geoghegan graduated M.A., M.B., B.Ch., B.A.O., Trinity College, Dublin, in 1896, and M.D. of the same university in 1898. He attained the rank of Fleet Surgeon on May 15th, 1915.

Surgeon Wood-Robinson was educated at the Middlesex Hospital, where he was house-physician; he took the diplomas of M.R.C.S. and L.R.C.P. in 1914. He received his commission as temporary Surgeon R.N. on March 18th, 1915.

Surgeon MacCormac, aged 44, was the elder son of Mr. William MacCormac, of Banbridge, co. Down. He took the 8 otish triple qualification in 1894. He practised at one time in Leicester, but removed to London, and was appointed anaesthetist to the Royal Dental Hospital, Leicester Square. On the outbreak of war he received a commission as surgeon, and was appointed to *H.M.S. Statesman*, being subsequently appointed to the *Black Prince*.

H.M.S. Ardent.

Surgeon-Probationer John E. McIntyre.

H.M.S. Nomad.

Surgeon-Probationer David J. T. Oswald, R.N.V.R.

H.M.S. Nestor.

Surgeon-Probationer Alexander Joe, R.N.V.R.

Mr. Joe was the son of Mr. and Mrs. John Joe of Brechin. He was in his last year at Edinburgh University when war broke out and at once volunteered for service.

H.M.S. Shark.

Surgeon-Probationer Robert Walker, R.N.V.R.

Surgeon George B. Moon, R.N.; and Surgeon-Probationers David H. Ferris, Hugh J. Dingle, and John Hislop of the R.N.V.R. were also killed on other ships.

Surgeon Moon was educated at Birmingham and Edinburgh, and took the triple Scottish qualification in 1909. He was at one time assistant medical officer to the Kent County Asylum, Barming Heath, and joined the navy with a temporary commission on November 27th, 1914.

Wounded.

Staff Surgeon Bertram R. Bickford.

ARMY.

Killed in Action.

Captain D. Waterston, Canadian Army Medical Corps, whose death was reported last week, was the son of Thomas Waterston, of Montreal, Canada, and was 26 years of age. He graduated in arts and medicine at McGill University, Montreal, and was appointed captain in No. 9 Canadian Field Ambulance in January last. He was killed while serving in a dressing station in the trenches on May 22nd.

Captain J. G. Mackenzie, Australian Army Medical Corps.

Died of Wounds.

Captain William Norman Watson has died of wounds. He was the second son of the late Rev. William Watson, Kiltearn, Ross-shire, and Mrs. Watson of Edinburgh, and was 27 years of age. He received his education at the University of Edinburgh, where he graduated M.B., Ch.B. in 1913. He joined the R.A.M.C. in December, 1914, and was attached to the King's Own Scottish Borderers. Captain Watson won the Military Cross at the battle of Loos, and was decorated by the King in April last, in which month at the request of the commanding officer he took a combatant commission. Last month he was wounded in the head, and he died in a casualty clearing station. His elder brother, Captain Allan Watson, R.A.M.C., is on active service, so also is his younger brother, Captain Stanley Watson, with the Cheshire Regiment.

Died on Service.

Lieutenant Harry John Sullings Kimbell, R.A.M.C., died in a nursing home in London on May 28th. He was educated at St. Bartholomew's and took the qualifications of M.R.C.S. and L.R.C.P. Lond. in 1907. After serving as house-physician of the West End Hospital for Nervous Diseases, house-physician of the Soho Women's Hospital, resident medical officer of the City of London Lying-in Hospital, and senior house-surgeon of Bedford County Hospital, he went into practice in Richmond Road, Dalston, London, N.E. He took a temporary commission in the R.A.M.C. last August, and was recently in charge of the Preston Hall Hospital at Maidstone.

Lieutenant Harry Rathbone Griffith, R.A.M.C., died at Press Heath Camp, Whitchurch, on May 21st, aged 50. He was the fourth son of the late Rev. Joseph Griffith, Rector of Pentreath, Anglesey, and was educated at Trinity College, Dublin, where he graduated as B.A., M.B., B.Ch., and B.A.O. in 1889, and as M.D. in 1893. He was in practice at Portmadoc, North Wales, where he was Admiralty Surgeon and Agent, and medical officer to the Post Office.

DEATHS AMONG SONS OF MEDICAL MEN.

Barnes, John Christopher Craven, Captain the Border Regiment, youngest son of Lieutenant-Colonel H. J. Barnes, R.A.M.C. (retired), of Greencroft, Colyton, Devon, killed in action on May 28th, aged 22. His commission as lieutenant was dated November 20th, 1914.

Paterson, Richard Eadson, Lieutenant R.N., younger son of Professor A. M. Paterson, of 21, Abercromby Square, Liverpool, killed in action on *H.M.S. Fortune*, in the great naval battle fought off the coast of Jutland on May 31st.

NOTES.

HONOURS.

THE names of the following members of the medical profession appear among those upon whom the King, on the occasion of his birthday, has bestowed distinctions in connexion with the military operations in the field:

C.B.

Surgeon-General J. J. Dennis, R.N.
Fleet Surgeon E. C. Lomas, D.S.O., R.N.
Surgeon-Generals W. G. A. Bedford, C.M.G., A.M.S., R. Porter, A.M.S., T. J. O'Donnell, D.S.O., A.M.S.
Colonels A. F. Blenkinsop, A.M.S., R. H. Luce (T.F.), O. R. A. Julian, C.M.G., A.M.S.
Lieutenant-Colonel C. C. Cumming, R.A.M.C.
Major P. S. Lelean, R.A.M.C.

K.C.M.G.

Colonel (honorary Surgeon-General) W. D. C. Williams, C.B., Australian A.M.C.

C.M.G.

Colonels C. E. Harrison, C.V.O. (T.F.), H. N. Thompson, D.S.O., A.M.S., T. B. Beach, A.M.S., C. W. R. Healey, A.M.S., J. B. Wilson, A.M.S., A. F. L. Bate, A.M.S., E. C. Freeman (T.F.), A. Fullerton, A.M.S.
Lieutenant-Colonels H. E. R. James, C.B., R.A.M.C., A. H. Lister (T.F.), O. L. Robinson, R.A.M.C., H. A. Bray, R.A.M.C., E. W. Slayter, R.A.M.C., T. P. Jones, R.A.M.C., G. S. Thom, R.A.M.C., J. V. Forrest, R.A.M.C., L. Humphry, R.A.M.C., W. H. Willcox, R.A.M.C., Sir J. R. A. Clark, Bt., C.B. (T.F.), B. J. Newmarsh, Australian A.M.C., J. T. Fotheringham, Canadian A.M.C., P. C. Fenwick, New Zealand A.M.C.
Surgeon-Major B. Pares, D.S.O., Royal Horse Guards.
Major G. Hall (T.F.).

C.I.E.

Lieutenant-Colonel James Jackson, M.B., I.M.S., Inspector-General of Prisons, Bombay.
Major Frederick N. White, M.D., I.M.S., Assistant Director I.M.S. (Sanitary).
Captain A. G. J. MacIlwaine, R.A.M.C., Embarkation Medical Officer, Bombay.

D.S.O.

Bagshawe, Major H. V.; Bartlett, Major B. S.; Bourke, Lieut.-Col. E. A.; Chiles-Evans, Capt. D. B. (T.F.); Cowie, Surgeon-Major R. M. (1st Life Guards); Crosland, Major G. W. K. (T.F.); Darling, Major J. M. (S.R.); Farrant, Major C. (T.F.); Fawcett, Major (temp. Lieut.-Col.) R. F. M.; Forrest, Lieut.-Col. T. H.; Fraser, Major A. N.; Gairdner, Capt. E. D. (T.F.); Gallie, Lieut.-Col. J. S.; Grech, Lieut.-Col. J.; Henderson, Major P. H.; Heron, Major G. W.; Heslop, Capt. A. H.; Husband, Capt. G. S. (I.M.S.); Osburn, Major (temp. Lieut.-Col.) A. C.; Sewell, Lieut.-Col. E. P.; Smales, Capt. W. C.; Sparkes, Major W. M. B.; Thomson, Major C. P.; Webb-Johnson, Capt. (temp. Major) A. E. (T.F.); McLean, Major J. B. (Aust. A.M.C.); Brown, Capt. T. F. (Aust. A.M.C.); Campbell, Capt. (temp. Major) R. D. (Aust. A.M.C.).

Military Cross.

Blandy, temp. Capt. G. S.; Brechin, Capt. W. A. (T.F.); Bremner, temp. Capt. A.; Bruce, Capt. L. C. (T.F.); Butler, temp. Capt. W. H.; Corkey, temp. Lieut. I. W.; Douglas, Capt. W. R. (T.F.); Drury, Capt. K. K.; Dudgeon, temp. Capt. C. R.; Dyas, Capt. G. E.; Edwards, temp. Capt. A. C.; Evans, Capt. T. J. C. (I.M.S.); Farrow, Capt. J. F. (T.F.); Fraser, Capt. A. D.; Galbraith, temp. Lieut. C. T.; Gilmour, Capt. J.; Gordon, Capt. S. (I.M.S.); Grant, Capt. G. R. (S.R.); Greville, temp. Capt. E. R. G.; Houston, Quartermaster and hon. Lieut. C. F.; Keep, temp. Capt. A. C.; Kendrew, temp. Capt. A. J.; Lovell, Capt. C.; Macdonald, temp. Capt. M. A.; McCallum, temp. Lieut. J. S.; McCammon, Capt. F. A.; MacCormack, Capt. J. D.; McGibbon, temp. Lieut. P.; Milne, Capt. H. S. (S.R.); O'Brien, temp. Lieut. J. W.; Orr-Ewing, temp. Capt. H. J.; Panton, Capt. H. F.; Power, Capt. D'Arcy (S.R.);

Robinson, Capt. G. E. J. A. (T.F.); Rowe, Surgeon-Capt. W. T. (South Notts Hussars, Yeomanry); Sampson, temp. Capt. H. H.; Shore, Capt. L. R.; Stocker, Lieut. C. J. (I.M.S.); Swan, temp. Capt. M. A.; Taylor, temp. Capt. D. C.; Whitton, temp. Lieut. N. S.; Wilkin, Capt. H. F. (T.F.); Clarke, Capt. and Quartermaster A. E. (Aust. A.M.C.); Boddam, Quartermaster and hon. Lieut. E. T. (Aust. A.M.C.); Kidd, Capt. G. E. (Canadian A.M.C.).

Major George Kilner Crosland, who has been awarded the D.S.O., is President of the Huddersfield Division of the British Medical Association. When war broke out the 5th Duke of Wellington West Riding Regiment, in which he held a combatant commission, was mobilized, and he accompanied the battalion as second in command; he served with it until the end of March, 1916, when he was allowed to return to medical duties in Huddersfield. He was gazetted major in August, 1914. He had served as civil surgeon with the South African Field Force for sixteen months during the South African war, and received the Queen's medal with three bars. Major Crosland served fourteen years as a combatant officer in the old 2nd Volunteer Battalion and 5th Territorial Battalion of the Duke of Wellington's West Riding Regiment.

To be Brevet Colonel.

Major (temporary Brigadier-General) A. C. Geddes, M.D., unattached list (T.F.).

The names of the following officers are included in the list of officers who have been awarded the Distinguished Service Order or the Military Cross in a special supplement to the *London Gazette* of May 30th:

D.S.O.

Temporary Captain Thomas Lewis Ingram, R.A.M.C. (attached 1st Battalion, Shropshire Light Infantry). For conspicuous gallantry and devotion to duty. He collected and attended to the wounded under very heavy fire, and set a splendid example. Since the commencement of the war he has been conspicuous on all occasions for his personal bravery.

Military Cross.

Captain James Couper Brash, M.B., 10th Field Ambulance, R.A.M.C. (Special Reserve). For conspicuous gallantry and devotion to duty. He went to an artillery dug-out which had received a direct hit, and, assisted by two men, extricated the wounded and administered first aid under heavy shell fire.

Captain Henry Percival Hart, M.B., R.A.M.C. For conspicuous gallantry and devotion to duty when, although himself wounded, he went out, dressed, and brought into safety the wounded under heavy shell fire.

Temporary Captain Philip Randal Woodhouse, M.B., R.A.M.C. (attached 1st Battalion Irish Guards). For conspicuous gallantry and devotion to duty. He tended the wounded under heavy shell fire, and, though himself wounded, continued his work. On another occasion he went across the open under shell fire to attend to the wounded.

Temporary Lieutenant William John Knight, M.D., 73rd Field Ambulance, R.A.M.C. For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station under heavy shell fire. He continued to attend the wounded with great coolness.

MENTIONED IN DISPATCHES.

Dispatches reporting the reduction of the Germany colony of the Cameroons, in West Africa, from Major-Generals Sir Charles Dobell and Cunliffe, were published on June 1st. Among a considerable number of officers and non-commissioned officers mentioned in these dispatches for good service are the names of the following medical officers and men:

In Sir Charles Dobell's dispatch: Lieutenant-Colonel J. C. B. Statham, O.M.G., R.A.M.C.; Major E. B. Booth, D.S.O., R.A.M.C.; temporary Captain T. M. R. Leonard, West African Medical Staff, and Sergeant G. Price, R.A.M.C.

In General Cunliffe's dispatch: Drs. J. C. M. Bailey, W. S. Clark, W. E. S. Digby, W. H. Peacock, T. H. Saffern, C. E. S. Watson, and R. F. Williams, all of the West African Medical Staff; and Sergeant R. E. Harvey, R.A.M.C.

THE BRITISH RED CROSS.

The annexe of the Star and Garter Home at Richmond for incurably helpless soldiers and sailors is now full of cases, all of a serious character. The arrangements for massage and electricity are complete, a shelter for men who can go on to the Terrace is finished, and a marquee is being erected.

The six launches provided by the motor boat department which served through the Dardanelles expedition have been transferred to Egypt and have been working in the Suez Canal carrying stores; ten launches have been at work for some time on the Tigris; five more have been sent to Basra towards the end of May, and two small runabout launches are being sent to Basra, as well as four large and two small launches which were taken out by a Government transport on May 25th. The dimensions of the large launches are standardized; they are 40 ft. long and 9 ft. broad, with a draught of 2 ft. 4 in. Each provides for sixteen lying down cases, which can be carried either fore and aft or athwart the boat, and between fifty and sixty sitting up cases. In addition a hospital ship 150 ft. long by 30 ft. broad, with a draught of 3 ft., is being built for service on the Tigris. It will carry fifty or sixty cots, and will be equipped with ice-making plant capable of turning out two tons

of ice a day, which will be distributed between Amara and Basra, a distance of 130 miles; the boat provides also accommodation for doctors and orderlies.

The War Executive Committee, at its meeting on May 17th, received the report from Sir Arthur Lawley, who had paid a visit to Switzerland at the request of Mrs. Grant Duff, the wife of the British Minister at Berne, who is engaged in sending bread and other parcels to prisoners in Germany. The following resolution was unanimously adopted on a motion of H.R.H. Princess Christian, seconded by the Duchess of Devonshire:

That, having received the report of the British Section of the "Bureau de Secours aux Prisonniers de Guerre," British Legation, Berne, prepared by Sir Arthur Lawley, the Committee is sensible of the great work that is being done in connexion with British prisoners. The Committee realizes that the record achieved by Mrs. Grant Duff, together with her zealous helpers, is one which could only have been attained by a generous self sacrifice. The Committee desires to place on record its admiration of the work which is being done by the above for the comfort of the British prisoners.

BRITISH AND GERMAN PRISONERS IN SWITZERLAND.

The Swiss medical officers who have been in this country in connexion with the selection of German prisoners to be sent to Switzerland have completed their work. The arrangements were similar to those made between France and Germany, and prisoners were entitled to claim the right to be examined by the commission, which consisted of three British medical officers, one of whom acted as president, and two Swiss medical officers. The diseases, infirmities, and results of wounds considered as rendering prisoners of war eligible for internment in Switzerland are enumerated in a White Paper recently issued. The two first categories are tuberculosis of the respiratory organs, even in incipient stages, and tuberculosis of other organs; other diseases enumerated are chronic constitutional diseases, including poisoning by chlorine or carbonic oxide, chronic affections of the respiratory, circulatory, and digestive systems, and grave nervous conditions. Sir Edward Grey has called attention to the omission of malaria from the category of chronic constitutional diseases, which omission would seem to have been accidental.

The British Foreign Office, in suggesting to the American Ambassador in London that an agreement should be made for the internment of invalid prisoners of war in Switzerland, also suggested that the Swiss medical men deputed should inspect all places of internment and hospitals in which prisoners of war were under treatment in the United Kingdom. The Swiss medical officers have reported very favourably on the arrangements in this country.

The first train conveying British prisoners from Germany reached Zurich on May 29th; it contained 32 officers and 272 men, and another train, containing 150 men, arrived the following day. Both parties received a friendly welcome at Zurich and all along the route to Chateau d'Oex.

Sir Edward Grey has stated in a written answer that four additional members of the United States Embassy at Berlin had recently been appointed to inspect camps in Germany in which British prisoners of war were interned. The Embassy was showing great energy in the matter, and between May 9th and 23rd no fewer than thirty-four working camps near Berlin were inspected. Reports on a large number of camps in Germany have recently been published in a White Paper.

In reply to Mr. Dundas White on June 1st, Sir Edward Grey said that no steps had yet been taken to endeavour to arrange for the transfer to a neutral country of prisoners of war interned in Austria-Hungary, Turkey, or Bulgaria.

England and Wales.

LONDON COUNTY COUNCIL.

At its meeting on June 6th the London County Council agreed to a request of its Midwives Act Committee, supported by the Education Committee, that classes should be opened for the instruction of midwives. Two classes are to be opened accordingly, one for the north and the other for the south of the Thames, at a cost which is expected to be about £175 per annum.

The Council at the same meeting agreed to extend for a further twelve months the arrangement for supervising certain mental defectives by entrusting them upon agreed terms of payment to the London Association for the Care of the Mentally Defective. This plan was started a year ago, and the number of cases dealt with at present in this manner is upwards of 800. During the year 2,476 visits were paid to the homes of the defectives by the staff of the association, in addition to a great deal of help given by local workers. Quarterly visits are required as a minimum, and the supervision is said to be very satisfactory.

SANATORIUM TREATMENT IN LONDON.

At the meeting of the Insurance Committee on May 25th it was resolved to circulate a memorandum by the medical adviser (Dr. J. E. Squire) on the selection of cases for

admission to sanatoriums, to the medical officers of health in each metropolitan borough. The memorandum stated that cases in which institutional treatment was most likely to be economically remunerative were those of young adults in the early stages of the disease, and that as a general rule, in proportion as the age of the patient rose above 25 or 30 years, the probability of complete arrest diminished, while the length of time required to arrive at arrest of the disease (when this did occur) increased. The first requirement, therefore, was to utilize the beds chiefly for cases of early tuberculosis in young persons. It would not be desirable, however, to exclude all the older cases from sanatoriums, for many such patients were able to earn a livelihood with occasional breakdowns. Extra nourishment was only of value in treatment when it supplemented ordinary food, and might well be restricted to those who were waiting for admission to the institution; those recently discharged, whilst getting back to work; and to the more chronic cases, who, with such assistance, were able to keep at work of some kind. As to the length of stay in the sanatorium, a three months' recommendation represented an expectation of permanent benefit, and a two months' and one month's recommendation an expectation of temporary improvement, possibly up to working pitch. At the end of these periods a report should be furnished and extension granted at discretion. It was important that medical practitioners should point out to patients and their wives the value of hygienic home conditions in keeping up the improvement after discharge. In some cases the cause of breakdown leading to application for readmission was the inability or disinclination of the patient to find work, thereby confirming him in invalidism. After-care organizations would do well to give special attention to procuring suitable employment for discharged persons.

Ireland.

DR. STEEVENS'S HOSPITAL.

SIR ARTHUR CHANCE, F.R.C.S.I., has been appointed consulting surgeon to Dr. Steevens's Hospital, Dublin. During the early years of the hospital's existence the consulting surgeoncy was usually held by the Surgeon-General to the Forces in Ireland, who was, *ex officio*, a governor of the hospital. Among the surgeons-general were John Nichols (1730-67), William Ruxton (1767-83), Archibald Richardson (1784-87), George Stewart (1787-1814), Solomon Richards (1814-19), and Sir Phillip Cramp on, Bt. (1819-58). Among others who have held the position are Samuel Croker-King (the first President of the Royal College of Surgeons in Ireland), Ralph Smith Obre, Samuel Wilmot, James William Cusack, Robert Moore Peile, Christopher Flemming, Samuel George Wilmot, William Colles, Sir George Hornidge Porter, Bt., Edward Hallaran Bennett, and Sir Charles Bent Ball, Bt.

ULSTER MEDICAL SOCIETY.

The annual meeting was held in the Medical Institute, Belfast, on May 25th; the President, Dr. Gardner Robb, occupied the chair. The various annual reports were presented and passed, and the following officers were elected for the ensuing year:

President: Mr. Robert Campbell, M.B., F.R.C.S. Eng.
Vice-Presidents: Professor Symmers, M.B., C.M. Aberd., and Dr. Murphy (Lisburn).
Council: Mr. Howard Stevenson, B.A., M.B., F.R.C.S., Mr. R. J. Johnston, Dr. W. Burns, Dr. T. A. Davidson, Dr. Foster Coates, Dr. F. C. Smyth.
Honorary Treasurer: Dr. V. G. L. Fielden.
Honorary Librarian: Dr. W. L. Storey.
Honorary Secretary: S. T. Irwin.
Honorary Editorial Secretary: Dr. C. G. Lowry.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND.

The annual meeting of this society was held in the Medical Institute, Belfast, on May 30th, when the Vice-Chancellor of the Queen's University presided. Dr. V. G. L. Fielden read the annual report and the statement of accounts, which were received and adopted; and an appeal was made to all medical men in the neighbourhood

to join the fund, and so enable the committee to meet the local needs, and to be able to aid the poorer districts. Professor Symington was re-elected president, Dr. Fielden honorary secretary and treasurer, and a large committee representative of both country and town.

Scotland.

At a meeting of the Fife branch of the British Red Cross Society last week the interim county director (Dr. John Macdonald, Onpar), reported that on December 31st, 1915, there were thirty-one women's and fourteen men's Voluntary Aid Detachments in Fife, with a personnel of 955 women and 390 men.

At a meeting of the Fife and Kinross Education Committee on June 1st it was reported that the work of school medical inspection was practically at a standstill, as all the four assistant school medical officers were away. The Education Department had expressed a wish that the inspection should be continued, and the committee decided to advertise for a doctor—male or female—in order that the scheme might be continued in a curtailed form.

India.

THE LADY HARDINGE MEDICAL COLLEGE, DELHI.

It is announced that the funds raised or promised in Bombay for the Lady Hardinge Medical College, Delhi, will provide for the erection of three cottage wards, an administrative block, and a senior professor's bungalow, leaving a balance sufficient for the establishment in Bombay of a maternity home to be named the Lady Hardinge Memorial Home.

WAR FUNDS.

Generous gifts continue to be made in India to various war funds. The Maharajas of Panna and Datia have offered to establish and maintain at their joint cost a convalescent hospital at Datia for one hundred sick and wounded soldiers, and the Maharajah of Sirohi is maintaining a convalescent home for sick officers from Mesopotamia. The Rani of Dhar and Seth Kastur Chaud of Indore have given motor ambulances. The St. John Ambulance Association has recently been given a lakh of rupees by the Bettiah Raj and half a lakh by the Maharaja of Darbhanga. The Hooghly District Centre has given a fully-equipped laboratory launch for service in Mesopotamia, and a second is now under construction, being a gift from the same place through Lady Carmichael's Fund. The association has also received two large ambulance flats to take twenty-six cases, the cost of which has been mainly subscribed in Calcutta. Two motor launches, one the gift of the Central Provinces and the other of Mrs. McLeod of Bombay, are now nearing completion in Calcutta; all these boats are for service in Mesopotamia. Five motor ambulances have been given by the Birbhum District, Bengal, and several others are being prepared, including one from the Punjab Chiefs' Association and another from the Maharaja of Sirmur. The last-named chief has also lent a house at Dehra, and is endowing several beds in the war hospital there for a year. The Central Provinces, through Lady Robertson, have guaranteed 1,500 rupees a month towards the upkeep of the Indian Red Cross Dépôt at Basra.

DR. PUIG Y SALS has reported to a Barcelona medical society the results of a statistical study which has led him to the conclusion that at the present rate of increase the population of Catalonia would take more than two centuries to double itself. Such increase as there was, he said, was largely accounted for by immigration of foreigners and of natives of other parts of Spain. The physiological increase of population in Catalonia fell, between 1886 and 1905, from an annual rate of 5.1 to one of 2.5 per 1,000. More recently it was 3.9, whereas for the rest of Spain it was a little over 9. The rate of increase was lower in Catalonia than in any country in Europe except France. He attributed this to a low birth-rate combined with a high mortality.

Correspondence.

SCIENCE AND ANTISCIENCE.

SIR,—Nothing measures more clearly the intellectual condition to which Britain has fallen than the fact that, even during the course of a life-and-death struggle, when one would think that every person not quite an idiot would be employed in some way, the crank papers continue to be hawked about in the streets. These papers pursue their absurdities just as when Britain had reached its lowest point of intellectual development before the war. A recent note on the cause of malaria in the *Abolitionist* is a typical production. In the *Journal of the Royal Naval Medical Service* for January, 1916, Staff Surgeon Leslie M. Morris, R.N., wrote an interesting account of the occurrence of malaria in H.M. ships *Hermione* and *Bristol* at Tampico in Mexico during 1914. The place is an intensely malarious one, as it contains large marshes in which multitudes of Anophelines (malaria-carrying mosquitos) breed. *Hermione* arrived without any protection in the way of wire gauze on December 13th, 1913. She was anchored fifty yards from the river bank, and the crew were forthwith attacked by legions of mosquitos, so much so that "it was at once realized that it would be necessary to screen the ship without delay." Of course this ought to have been done before the ship was ever sent to such a place. As quite possibly one in four of the mosquitos that came on board were infected, it is obvious that a large proportion of the crew could easily have become infected even during the first night of their arrival; and, as was to be expected, cases began to occur on the twelfth day after arrival. Meantime the officers set to work with promptitude to screen the ship—this could certainly not be done in a day. Another outbreak occurred in May, when the breeding season of mosquitos again reaches high proportions. This outbreak occurred in spite of the precautions; but here again every one with the smallest knowledge of the subject knows that it is absolutely impossible by any known precautions to prevent malaria entirely in a place where large numbers of malaria-bearing mosquitos exist—just as it is impossible by means of sandbags and shelters to protect an army from all casualties when thousands of shells are falling upon them. Sailors are especially difficult to protect, because, in spite of warnings, they will expose themselves to mosquito bites—owing to the irksomeness of confinement within wire gauze in a hot climate.

The *Abolitionist* seizes upon this text to mislead its foolish readers; but the writer of the note uses an old argument so silly that it should be again exposed as an example of this kind of literature. "Malaria, as all our readers know," he says, "is said to be caused by the mosquito. The difficulty in accepting this theory lies in the fact that the mosquito can only produce malaria in a human subject after it has fed upon a human already suffering therefrom; it still remains, therefore, a puzzle as to how the first man got it!" In the numerous lectures which I have delivered on the subject this difficulty is often raised at the end of the lecture; and I can always detect the man who is going to raise it by the vacuous expression of his face. The classical method of answering is to ask another question—namely, if the chicken comes from the egg and the egg from chicken, which began first? The *Abolitionist* seems to think in its dull way that there is some logical meaning in such a question. It implies that, because we cannot frame theories to explain our observations of to-day by what happened millions of years ago, our observations of to-day are, therefore, incorrect! Hence, as we cannot state whether the chicken or the egg came first, therefore it is not true that chickens come from eggs or eggs from chickens at all! As a matter of fact many explanations have been given of the point raised by the *Abolitionist*; but we must reply as Dr. Johnson is reputed to have done: "Sir, I have furnished you with an explanation—I cannot furnish you with an understanding." Whether his particularly childish argument ever deceived the writer in the *Abolitionist* himself, or whether it is merely put forward with the knowledge that his subscribers were too foolish not to be taken in by it, I cannot say; but these crank papers largely subsist on the subscriptions of old ladies, who do not know what to do with their money, persons of the kind who

may see pulling about horrible little dogs to defile our streets and squares in London.

The writer of this precious passage in the *Abolitionist* continues: "In our opinion, the responsibility lay with the lagoons and marshes which exist on both sides of the river, and which send forth their poisonous atmosphere from the moist, decaying vegetable matter under the heat of a burning sun." The marshes certainly cause malaria, but by sending out the mosquitos, not by emitting a poisonous atmosphere. But note the lofty strain of the scientific genius who wrote this passage—"In our opinion." One wonders whether even the most feeble-minded reader of the *Abolitionist* believes that the editor and staff of that journal have the smallest right to any opinion upon such a technical subject, or indeed upon any scientific subject.

But there is not only false argument in the paragraph referred to, but also some suppression which can hardly be otherwise than deliberate, because the author, in order to enforce his suggestion that the protective measures failed entirely, omits to mention the fact that *Hermione* was not protected at all when she first arrived, and secondly, omits all reference to the summing-up by Staff Surgeon Morris, that, "as the result of experience gained in these two ships employed in a highly malarial district, I conclude that the measures taken to screen the ships effectually prevented a very extensive outbreak of malaria." And he adds, "only one officer of the two ships contracted malaria," the truth being, of course, that the partial measures partially prevented the disease, and that without them probably every person in the ship would not only have suffered from malaria, but that many of them would have died of it. In conclusion, the author of the paragraph talks about "the folly of Sir Ronald Ross's bird experiments and their proofless demonstrations." The "proofless demonstration" is a new kind of philosophic entity, and it is almost impossible to conceive how persons considering themselves to be sane can be taken in by such twaddle.—I am, etc.,

London, June 6th.

RONALD ROSS.

THE WAR OFFICE MEMORANDUM ON AMPUTATIONS AND AMPUTATION STUMPS.

SIR,—The War Office memorandum on amputations and amputation stumps is an excellent idea and should go a long way to obtain the best results for those members of our fighting forces unfortunate enough to lose their limbs. Two points in the memorandum, however, seem to me to call for criticism.

In the first place it leads the reader to suppose that in the case of a lower limb amputation it is desirable that the patient's weight should ultimately be borne on the end of the stump. This is a very common error, and since the war began I have several times seen men trying to walk on limbs so constructed that the weight had to be borne in this way, with the result that they were making very slow and painful progress. This is a most important point and cannot be too much emphasized. The end of an amputation stump, with the single exception of a Syme's amputation, should not, and cannot, bear the weight of the body. Attempts to make it do so are entirely wrong. In the case of an amputation above the knee the patient should bear all the weight on the top and sides of the stump—that is, should sit on the top of the limb. In an amputation below the knee the weight should be taken on the head of the tibia and fibula. It is never possible to take more than a very small amount of the weight on the end of the stump, and even this results in soreness. Sore stumps are the inevitable result of trying to take pressure on the end.

The other criticism has reference to the time after operation at which an artificial leg should be fitted. It is advised in the memorandum that four months at least should elapse. Why wait four months? The proper time to begin using an artificial limb is as soon as the wound is soundly healed. Shrinking of the stump always results from using an artificial leg owing to the unaccustomed pressure, and no amount of waiting will prevent this. On the other hand, it is of vital importance that the muscles which move the stump shall not be allowed to waste, as good use of the limb depends upon these muscles. The sooner, therefore, that the limb is fitted and the patient encouraged to attempt to walk, the sooner will he be able

to make good use of the limb, and he will not be handicapped by having to develop muscles which have been allowed to waste.—I am, etc.,

London, W., May 30th. P. LOCKHART-MUMMERY, F.R.C.S.

THE CONTROL OF VENEREAL DISEASES.

SIR,—As one who has studied Sanger's *History of Prostitution*, together with most of the modern books written in English on the subject, I should like to join issue with the view put forward by W. J. Young, of Cambridge, in your issue of May 20th. In regard to prostitution he apparently agrees with Thucydides that these things "always have occurred and always will occur so long as the nature of man remains the same." Surely this is a hopelessly unscientific attitude. The "nature of man" never does remain the same; it is capable of infinite variety in its manifestations.

Sanger wrote his book fifty-seven years ago, and, while it is a very interesting study of prostitution in many parts of the world and from the earliest times, it is somewhat superficial and not altogether reliable in view of more recent research. Two very important books have been written since Sanger published his book, and I think a careful study of Flexner's *Prostitution in Europe*, Chapters I, II, and III, and Havelock Ellis's *Studies in the Psychology of Sex*, vol. vi, will go far to prove that a great deal of prostitution has no relation at all to normal sex demand. Flexner rightly says:

The important point to remember, from the standpoint of practical policy, is this: Supply is to some extent artificially created, and demand is to some extent artificially forced; the artificial processes in question are in greater or less degree socially controllable and modifiable. . . . Human nature is indeed weak on the sexual side, but the mass of existing vice is out of all proportion to what would exist on that account alone.

It may be true that some forms of sexual irregularity will always be found in the world, but all modern investigation shows that its present volume is capable of enormous reduction. We have only just begun to give any serious thought to the problem of prostitution. In the past, as Sanger points out, the general method, applied by fits and starts in occasional bursts of virtue, was burning, flogging, or imprisoning the women. It is scarcely wonderful such treatment failed, especially when one considers that sexual irregularity has generally been expected in men and chastity in women. The two theories are mutually destructive.

With regard to the little effect which moral societies have upon vice, no body of people is more conscious of this fact than the members of such societies, but they know, too, that the greatest obstacle to their work is neither the prostitute nor her customer. The thing which makes all moral and social reform work so intensely difficult, which produces both the prostitute and her partner, is that great body of public opinion which tacitly upholds the double standard of morals, and when it sees the result of its doctrines murmurs meaningless platitudes about "human nature."—I am, etc.,

ALISON NEILANS,

Assistant Secretary, The Association for Moral and Social Hygiene, 19, Tottenham Street, Westminster, S.W.

May 23rd.

"THE SOLDIER'S HEART."

SIR,—Sir James Barr's recent paper on "The Soldier's Heart," in the *BRITISH MEDICAL JOURNAL* of April 15th, contained at least one remarkable sentence: "On causation he (Sir James Mackenzie) is not the only writer who flies to that resort for the destitute—microbes and their toxins—to explain all the ills to which flesh is heir."

Sir James Barr points out the association between "soldier's heart" and trouble in the ductless glands, and gives us a sketch of a vicious circle. He does not throw any light upon the factors which cause these glands to misbehave, though he approaches, somewhat inconsistently, the bacterial toxin theory in another sentence when he says, "In some febrile affections, such as diphtheria and pneumonia, the adrenalin function may be inadequate, and thus the controlling influence over the vasomotor system is lessened." Why must we draw the line rigidly at these two bacteria? Hundreds of other bacterial ferments have been described (Lehmann and Neumann's *Bakteriologie*) as primary or secondary causes of patho-

logical states. A rise of temperature is not always found in subacute processes of a septic nature. The endotoxins of the influenza bacillus, *B. diphtheriae*, the gonococcus, the staphylococcus, and the great family of streptococci possess a wide range of action from which no tissue of the body can be regarded as absolutely safe, not even the elements of the ductless glands.

Summing up the gentle discussion evoked by his paper, he says: "The many toxæmias to which he (Dr. Harry Campbell) refers can easily be eliminated in cases of soldier's heart." It would be interesting to know the precise laboratory methods which Sir James Barr recommends for this important eliminative process. The field of a one-twelfth inch lens is very small, and Sir James Barr is right to insist upon the wide survey, particularly in these days of excessive specialization. But can he justify his apparently contemptuous references to the students of microbiology who are seeking the truth about that little leaven which leaveneth the whole?—I am, etc.,

London, W., May 29th.

H. LYON SMITH.

LICE AND THE CLOTHES BRUSH.

SIR,—In the *JOURNAL* for April 29th, p. 630, is an account of the discussion on the means of lessening the incidence of infestation by lice. I note that one important adjuvant in the treatment of the clothing was not mentioned—brushing the seams of the clothes thoroughly. Personally, I rely very greatly on this treatment, especially for breeches. The men are made to turn the breeches inside out and thoroughly brush out the seams, any tacking threads being removed for this purpose. Paraffin, washing in cresol, and brushing, have in my unit taken the place of other methods in the destruction of lice.

I believe it was the late Field Marshal Viscount Wolseley who laid great stress on rubbing, shaking, and brushing the clothes when means of washing were not obtainable.—I am, etc.,

May 17th.

JOHN S. CLARKE,
Capt. R.A.M.C.

PARAFFIN FOR LOUSINESS.

SIR,—An effective and easily applied remedy for pediculosis I have found in paraffin oil swashed over the skin from neck to heels, avoiding the scrotum. The soldier strips, and dipping his hands into the bowl of oil slaps himself over his front and the orderly completes the business behind. There must be no rubbing or dermatitis would follow inevitably. The wetting being completed the man resumes his clothing at once.

I have employed this treatment in over a hundred cases, and with invariable success after one application only.—I am, etc.,

West Mersea, June 3rd.

B. HALL.

HOW MEDICAL WRITINGS MAY BE GIVEN A MARKED DEVELOPMENT.

SIR,—I think Dr. Mercier has earned the thanks of the profession in reminding us of some of the rules of English composition which were taught to us at school, one of which—namely, to avoid tautology—Dr. Bramwell breaks more than once in the first sentence of his reply. Another rule which might be more frequently observed is to use a monosyllable wherever possible; yet another—study your Bible.—I am, etc.,

West Bridgford, June 3rd.

H. E. BELCHER.

SIR,—Dr. Mercier is doing medical literature a distinct service by starting a crusade against the word "marked."

I first came across this word in full force in the medical department of a prominent American university. Since then it has spread through medical literature like a miasma.

In the meaning of "quite apparent" the word is permissible, but the word has run amok, and, as now used, is guilty of almost anything. It conveys to me about as much meaning as "damn," and other profanities. It may not be too much to ask medical writers to spare us the nauseating effect of the constant repetition of this word.—I am, etc.,

France, June 1st.

FRED. W. E. BURNHAM.

SIR,—Of course Dr. Bramwell knows best, and I must reconcile myself as best I may to the doctrine that "marked" is the only adjective, and "markedly" the

only adverb permissible in medical writings. I am very, that is to say markedly, grateful to him for his strenuous, I mean marked, attempt to put me right; but when I find a writer making eight rather bad, I should say markedly marked, blunders in English in the course of one short letter, I have a decided, of course I mean a marked, disinclination to accept him as a final, or as it were marked, authority on the English language.

Following his advice, I have consulted the dictionary, and in it I find that a slop is "liquid carelessly dropped or spilt about," and sloppy means "covered with slops, loose, slovenly." These are precisely the qualities that I intended to express when I used the term "sloppy English." I meant language carelessly dropped or spilt about, loose and slovenly language. No doubt I ought to have said marked English, but *pace* Dr. Bramwell, I do not consider "sloppy English" a meaningless expression, nor do I consider it "somewhat vulgar," but then I cannot claim to be as genteel as Dr. Bramwell.

"M.D." has me on the hip, I must confess. I was so confident that Tennyson was the author of the quotation that I neglected to verify the reference, and I have met with the deserved and inevitable fate of those who neglect to verify their references.

Dr. Lipetz misunderstands me. I do not say it is incorrect to employ the word "marked" as an intensive. For use in this capacity it will serve. It is not nearly as effective as blessed, or bally, or blooming, or some other word beginning with a "b"; but it will serve. I did not say that this use of the word is incorrect, and it is not incorrect. It is only stupid. What I intended to convey is that it is incorrect to use the adjective "marked" when we do not mean marked, but mean some other quality. If Dr. Bramwell and Dr. Lipetz like to use intensives, or if they prefer to use a wrong word instead of a right one, on their own heads be it; no man can be compelled to write good English if he prefers to write bad. Dr. Lipetz asks if the word "marked" has not been used as an intensive by good English writers. The answer, in classic phrase, is in the negative. He asks also if it has not gained general acceptance. I tried in my previous letter to point out that it has gained general acceptance among medical writers, and that it is high time it gained general rejection; but I founded my plea on the supposition that the indiscriminate use of the word was due to carelessness, or laziness, or want of consideration, or some other remediable cause. I must confess it did not occur to me that any one could be found to defend it as a justifiable practice. I should as soon have expected a defence of the practice of throwing orange peel into the street, or slopping tea on the tablecloth, if Dr. Lipetz will kindly excuse these weird and uncouth expressions.—I am, etc.,

Parkstone, Dorset, June 3rd.

CHAS. A. MERCIER.

FEES OF LOCUMTENENTS.

SIR,—I would like, through the medium of your paper, to call attention to the excessive fees demanded now by locumtenents. For the last two years I have paid £7 7s. a week and expenses, but now £9 9s. a week is demanded indoors, expenses, and fees for the day travelling. I am well aware of the fact that the greater the demand the greater must be the remuneration, but there ought to be a limit. A few years ago men were glad to get £4 4s. a week, and if £7 7s. is paid I think it ample, especially now, when general practitioners are harassed in many ways, and doing much gratuitous and philanthropic work. If a general practitioner desires to take a week or two's respite for his health sake, I think it a scandal that they should be "blood-sucked" by members of their own profession. I would advise that all practitioners should boycott all locumtenents demanding more than £7 7s. a week, and this, I am sure, would bring them to understand what is their duty.—I am, etc.,

May 27th.

M. W. B.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

SIR,—The time has come again for the election of Fellows into the Council of the College. The time has therefore come again to raise a protest against the exclusion of Members of the College from sitting on the Council.

If the war has taught us one principle more than

another it is to recognize the rights of minorities and the importance of championing at all costs those who are suffering from injustice.

No one who knows anything of the history of the Royal College of Surgeons but recognizes that the perpetuation of an oligarchy and the disenfranchisement of a democracy lies at the root of the stagnation of life which exists in the Council of the College to-day.

During the last few years the medical profession has been through stirring times and great crises. A Council worthy of the name should have taken up these social and political problems, and have proved itself a guide, a protector, and a tower of strength to the surgeons of England. The Council, alas! has been satisfied to let great opportunities slide, and the only cure for this sterility is the introduction of new blood and the extending of the franchise to every Member of the College.

I have listened year after year to the excuses made by the President of the College for the shelving of this important reformation, and have been surprised at the absence of logic and of administrative foresight in those who are considered sufficiently wise to be admitted as members of the Council of a great College.

Many great changes which hitherto have been considered impossible have been brought about during the last two years by short Acts of Parliament, and if no other method can be found to convince the Council of the Royal College of Surgeons that they are out of touch with the sentiments and aspirations of the surgeons of England it may be necessary in this case also to utilize the machinery of Parliament.—I am, etc.,

London, E.C., May 28th.

JOSIAH OLDFIELD.

THE ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

SIR,—In reply to yours of May 20th, I have no personal grievance, but I do protest against the policy adopted in 1906 and 1911, by which no one, unless he is a member of the British Medical Association and nominated by the Association, has the "ghost of a chance" of being elected as direct representative of the profession on the General Medical Council. At the election in 1911 Dr. Latimer had the lowest number of votes, and that was 7,173; the next was Mr. George Brown with 3,424. Mr. Brown's friends worked hard, but were powerless against an Association with Divisions extending from Land's End to Berwick-on-Tweed. The Association, with all their efforts, could not secure one-third of the electorate. If the Association would be satisfied to elect two out of the four for England, they would have all that their numbers warrant. Only about one-half of the doctors in England and Wales are members of the Association. I suggest that the four draw lots for two representatives for the 1916 election, and leave two for the medical profession who are not members of the Association to elect. The cost to do anything like justice to an election is considerable. It would be a wise thing to do, if possible, and to have four electoral areas, so that we could get into touch with our representatives. It is war time, and thousands are on active service. Still it should not be a walk over for the Association. Since my letter appeared I have been spoken to, but I see no hope of winning. If I consent, it will be as a strong protest to the Association's policy. "The grasp all" legally when "not morally entitled" is not worthy of the British Medical Association nor its traditions up to the recent past.—I am, etc.,

Blackpool, May 25th.

J. BROWN, M.D.

Medico-Legal.

A CASE OF LEPROSY.

A CASE of some interest occupied Mr. Justice Darling and a special jury on May 15th, 16th, 17th, and 18th. It appeared that a Mr. Miller and his daughter, both of whom had lived for some time in India, took lodgings in July, 1914, at the house of a Mr. E. P. Humphreys in Bayswater. Mr. Miller was then suffering from leprosy. The following month Mr. Miller and his daughter took up their residence with Mr. Humphreys, and from that time until Mr. Miller's death in the following December he was attended by Dr. Harbord. On the occasion of Dr. Harbord's first visit to Mr. Miller at Bayswater Mr. Humphreys's manageress asked whether the former was suffering from an infectious disease, and was told he was not. In these circumstances Mr. Humphreys asked for damages on the ground that

It was no longer possible for him to continue to let lodgings at his house, and he also claimed the value of the furniture in the rooms which Mr. Miller had occupied. He made Miss Miller, Mr. Miller's executor, and Dr. Harbord all defendants to his action, which he based on breach of warranty, fraudulent misrepresentation, and conspiracy.

In addition to the above Miss Miller stated that she had seen lepers in India, and had suspected that her father was suffering from leprosy although she had no definite knowledge on the point, and a body of evidence was called on either side as to the nature of the disease in question. For the plaintiff, on the one hand, Dr. George Pernet, who was formerly the English editor of *Leprosy*, stated that the general view was that leprosy was communicated from one person to another, but in what way was not known. Dr. H. P. G. Bayon, late bacteriologist at Robben Island to the Government of the Union of South Africa, said that he had studied the disease in many countries, and had examined about 2,000 cases, and that in his belief leprosy was contagious, though not highly so. For the defendants, Dr. Harbord said that the danger of infection or contagion from leprosy was practically nil, and that there was no risk whatever if the patient's effects were properly fumigated. Dr. Abrahams, consulting dermatologist to the West London Hospital, stated that the overwhelming body of opinion was that leprosy was only slightly contagious, and that some other condition must be present to make it so. Sir Malcolm Morris, a member of the International Leprosy Commission, said that he had never known a case of one person catching the disease from another.

The judge, after summing up the evidence, left eight questions for the jury to answer. The questions, with the jury's answers, were as follows:

1. Was Mr. Miller, when he took the rooms, liable to infect persons or the furniture with leprosy, and did Mr. Miller or Miss Miller know this?—Yes.
2. Is leprosy infectious or contagious so as to be, in England, communicable from the leper to another?—Yes.
3. Did Miss Miller and Dr. Harbord fraudulently misrepresent that Mr. Miller was a fit and proper person to occupy the plaintiff's rooms?—Yes.
4. Did Miss Miller and Dr. Harbord conceal from the plaintiff that Mr. Miller was a leper which made him unfit to occupy the lodgings?—Yes.
5. Did Dr. Harbord, acting as agent for Miss Miller and Mr. Miller, state to Mrs. Humphreys that Mr. Miller was not suffering from any infectious or contagious disease?—Yes.
6. Were these statements untrue to the knowledge of Mr. Miller, Miss Miller, and Dr. Harbord?—Yes.
7. Did Mr. Miller, Miss Miller, and Dr. Harbord conspire to conceal the state of Mr. Miller from the plaintiff, and make false statements to him for that purpose?—Yes.
8. Damages?—£250.

Upon these findings of fact Mr. McCall, K.C., who appeared for Dr. Harbord upon the instructions of the London and Counties Medical Protection Society, submitted that judgement should be entered for his client. He pointed out that the charges against him consisted of conspiracy and fraudulent representation; that with regard to the former charge there could be no actionable conspiracy unless it was a conspiracy to infringe a legal right of the plaintiff, and that there was no legal duty upon Dr. Harbord to disclose to the plaintiff the nature of the disease from which Mr. Miller was suffering or legal right vested in Mr. Humphreys to have such disclosure. With regard to the charge of fraud, counsel submitted that it must be shown that Dr. Harbord had made a statement without belief in its truth or recklessly as to whether it were true or false, and that there was no evidence that Dr. Harbord did not entertain the scientific belief which he had expressed—namely, that in this country leprosy was neither infectious or contagious. Mr. Gordon Hewart, K.C., for the other defendants, adopted the same argument.

Mr. Justice Darling, in giving judgement, said that there was no authority in law to support the proposition that there was a term implied in every contract to take furnished lodgings that the lodger was fit to occupy them, nor was there authority for saying that doctors who took patients to houses must make a full disclosure of the patient's state; such a rule would be difficult to enforce and difficult to define within reasonable limits. He held that there was no evidence to support the jury's finding that Miss Miller knew that her father was suffering from leprosy; that as regards Dr. Harbord's statement that Mr. Miller was not suffering from an infectious disease, the evidence was that he believed the risk to be "practically nil." In effect Dr. Harbord's opinion was that leprosy was not infectious in England. It could not therefore be said that Dr. Harbord's statement was fraudulent.

Upon these grounds judgement was entered for the defendants.

The Services.

EXCHANGES.

M.O. to R.F.A. Brigade attached to a naval division forming for service in France desires exchange with M.O. in 50th Division abroad.—Address No. 1950, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Captain R.A.M.C.(T), home service, wishes immediate exchange with officer in field ambulance, base hospital, or casualty clearing station.—Address 2200, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

UNIVERSITY OF OXFORD.

The following degree has been conferred:

M.D.—John Howell Evans.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—*† L. G. Phillips, *† S. Ritson (University medal), E. A. Celestin, W. M. Crombie, C. I. do Silva, J. A. W. Edden, D. S. Graves, I. H. Pearse, L. D. Phillips, Emma C. Pithman, A. L. Punch, L. N. Reece, D. G. C. Tasker, J. W. T. Thomas, A. H. Turner, Sibyl I. Welsh, A. Wai-tak Woo.
* Honours. † Distinguished in Medicine and Surgery.
‡ Distinguished in Midwifery and Diseases of Women.

The following have passed in one of the two groups of subjects:

Group I: Grace M. Griffith, C. E. Petley, B. Sampson, A. G. Simmins, E. C. Spaar. Group II: A. W. Adams, F. V. Bevan-Brown, R. M. Dannatt, W. H. Lloyd, Violet I. Russell.

Obituary.

DR. RIVERS-WILLSON, of Oxford, died at his residence in that city on May 19th, aged 63. He began life as a dispenser to the Radcliffe Infirmary, where he was able to study medicine, and, after working at the London Hospital, he took the diploma of L.S.A. in 1889. He set up in practice in Oxford and held for many years the appointment of district surgeon to the Oxford Medical Dispensary and Lying-in Charity. In 1912 he took an active part in opposing the original Government terms of the Insurance Act. Dr. Rivers-Willson prepared several educational works for the use of students, the best known being *Materia Medica and Pharmacy*; *Chemical Physics* and *Chemistry* were also useful compilations. All three were avowedly published for the benefit of candidates for the qualifications of the Conjoint Boards and the other diploma-giving corporations in the United Kingdom. Dr. Rivers-Willson was a Ph.D., a member of the British Medical Association, and a Fellow of the Royal Society of Medicine. He was an active member of the Oxford City Insurance Committee, and his health failed mainly in consequence of his exertions two years ago; yet he recovered and was able to discharge his medical duties almost to the date of his death. He leaves a widow and one son. The funeral took place at Wolvercote cemetery on May 25th.

DR. ALFRED GRACE, an elder brother of Dr. William Gilbert Grace, who died on October 23rd last year, has survived him just seven months, dying last week at Chipping Sodbury, Gloucestershire. Dr. Alfred was the second son of Mr. Henry M. Grace of Downend, Gloucestershire, where he was born on May 17th, 1840, being over eight years older than Dr. William Grace. He received his medical education at Bristol, and took the diplomas of M.R.C.S. in 1863 and L.S.A. in 1864. He was a member of the British Medical Association and Surgeon Lieutenant-Colonel, Royal Gloucestershire Hussars Yeomanry Cavalry. Dr. Alfred Grace was the last of five brothers, three of whom—W. G., E. M., and Frederick Grace—were famous cricketers. Alfred did not attain so much renown, though he played the game fairly. He was better known as a hunting man, being a superb rider.

THE death took place, on May 29th, of Dr. LÉON BLANC, the well-known consultant, at Aix-les-Bains (Savoie). Dr. Blanc was 75 years of age, and was well known in medical circles in London, where he usually spent the winter. He was the author of numerous communications bearing on "arthritis," and his persuasive eloquence did much to popularize the Aix treatment. He was the regular medical attendant of the late Mr. Pierpoint Morgan, who presented the town with a magnificent hospital, known as the Léon Blanc Hospital, to perpetuate the memory of his friend and medical adviser. A Savoyard of the old school and a past mayor of Aix, he died universally respected and regretted. He was Officier de la Légion d'Honneur.

Medical News.

THE name of George Cowie Grant, M.B., C.M., Dufftown, appears in the list of new justices of the peace for Banffshire.

WE regret to see the announcement of the death on May 27th of Dr. C. E. Fitzgerald, the well-known ophthalmic surgeon of Dublin.

DR. ROBERT ROBERTSON, J.P., Honorary Physician and Chairman of the Visiting Committee of the Royal National Hospital for Consumption, Ventnor, has been unanimously elected vice-president of the institution.

One of the most touching features of the funeral procession of General Gallieni on June 1st was a group of representatives of "Aide et Protection," the National Society of Mutual Aid for Mutilated Soldiers, in whose welfare the deceased general had shown a very active interest. The society, which already has a large membership of wounded men, was established by Ministerial decree, and is under the patronage of the President of the Republic.

THE national munition factories number seventy-five, and canteens have been established in all except a few small establishments the workers in which live close by. It has been found possible to provide a dinner of meat, vegetables, and a sweet for 8d. or 9d. The number of controlled works is about 3,500, and the provision of canteens for them is making good progress; firms which erect suitable buildings may set off their cost against excess profits. As was mentioned some time ago, the Health of Munition Workers Committee has issued a memorandum containing plans for temporary buildings for canteens.

WE learn from the *Journal of the American Medical Association* that the National Association for the Study and Prevention of Tuberculosis has received £20,000 from the Metropolitan Life Insurance Company to carry out a community experiment for three years with the object of demonstrating that tuberculosis can be controlled like any other infectious disease if right methods are adopted and adequate resources are available. It is proposed to choose a town or city of about 5,000 inhabitants, probably in New York or Massachusetts, and to apply there all the knowledge as to the treatment of tuberculosis available.

THE annual meeting of the Asylum Workers' Association was held on May 17th at 11, Chandos Street, W., the chair being occupied by the president, Sir John Jardine, Bt., K.C.I.E., M.P., who moved the adoption of the report, which was presented by the honorary secretary, Dr. Farquharson Powell. He drew attention to the war services of asylum workers, a very large percentage of male officers and attendants having joined the colours, while numerous nurses held Red Cross posts, or were employed in military nursing in the dozen or more asylums which had been converted into war hospitals. All, indeed, whether still remaining in asylum service or not, had felt the strain of the war, for asylum staffs had been seriously depleted, while the wards had become overcrowded in consequence of transfers of patients from asylums vacated for War Office purposes. The Executive Committee had continued their efforts to safeguard the interests of those serving as regards superannuation, etc., and it was hoped that they would be rendered secure by the recently passed Local Government Emergency Act. Private legislation was for the time suspended, but desirable amendments to the Superannuation Act of 1903 would be proceeded with as soon as opportunity permitted. The adoption of the report was seconded by Lieutenant-Colonel D. G. Thomson, R.A.M.C., president of the Medico-Psychological Association, and supported by Mr. Alfred Goodrich, late chairman of the London County Council Asylums Committee. Sir James Crichton-Browne proposed, in an interesting speech (in which he criticized adversely asylum treatment in Germany), the re-election as president of Sir John Jardine; this was seconded by Dr. G. E. Shuttleworth, and carried by acclamation. The election of the vice-presidents, Executive Committee, and officers was proposed by Dr. R. Armstrong-Jones of Claybury, and seconded by Dr. W. J. Seward, formerly of Colney Hatch Asylum, and, after other speeches by Dr. Fletcher Beach and the Rev. John Peck, the proceedings terminated. The balance sheet, made up to December 31st, 1915, showed £152 10s. to the credit of the association, the depletion of funds owing to diminution in annual subscriptions consequent on the war and other causes having been compensated by many generous contributions.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, Aitology, Westrand, London; telephone, 2631, Gerard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerard. (3) MEDICAL SECRETARY, Medisecra, Westrand, London; telephone, 2634, Gerard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects of which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

LOTHIAN desires to hear of a book giving hints as to exercises, games, and occupations suitable for use in neurasthenic cases.

ATTENDANCE ON SOLDIERS BY CIVIL MEDICAL PRACTITIONERS.

X. Y. Z. writes: During April I attended a private in a regiment. At the end of the month I sent in my account to the officer commanding on Army Form O. 1667. Up to date I have neither received the money due nor any acknowledgement of my letter. May I ask what experience other members have had in similar case?

LETTERS, NOTES, ETC.

COLD FEET AND STUFFY HEADS.

DR. E. LLOYD-OWEN (Criccieth) writes: I find that through omission on my part of three words in my letter (May 13th, p. 708) under the above heading some of my medical friends have been puzzled. The sentence should have read: "Is there not during sleep a certain amount of anaemia of the brain (in spite of the horizontal attitude) resulting from determination of blood to the feet, and indeed to every part of the body covered by the bedclothes?"

MEDICINE AND THE NATIONAL VOLUNTEERS.

DR. H. J. HILDIGE (Pinner, Middlesex) writes: Now that the Compulsion Act has passed and it has become probable that most doctors under 41 may have to go, I am anxious to know whether there is a corps that we doctors who are over the age limit could join to get instruction in ambulance work. If a certain number of men in each Division could be persuaded to join, instruction classes might be arranged in a central district and the ordinary duties of camp work imparted. I think before long the Government will be making more use of the volunteers and it would be as well if we men over 41 knew something of the duties of field work, of which I must plead ignorance.

VALUE OF TUBERCULIN TREATMENT.

MEDICUS writes: In an article on "Results of Sanatorium Treatment" in your issue of May 27th, p. 763, I see that tuberculin administration has been discontinued at the Midhurst Sanatorium. Is this the case generally?

My own experience may be interesting. Five years ago tubercle bacilli were found in my sputum (my age was 54). I went at once to one of the high altitude places in the Engadine, where tuberculin was given me for three months by an expert authority on the administration of tuberculin. At the end of that time my larynx was badly affected, and my voice had gone to a whisper; pain and dysphagia were marked. I returned to England and continued tuberculin for another four months with every precaution. Laryngeal symptoms continued and got steadily worse. On the advice of an eminent throat specialist, who had been through my trouble himself, I gave up tuberculin, kept absolute silence, and went to Madeira, never expecting to return. In six weeks my laryngeal symptoms were gone; at the end of four months I returned a different being. I have had no recurrence, thank God, up to date of laryngeal troubles; my voice, though not a Caruso one, has become audible once more, and my weight is normal.

Was the disappearance of laryngeal trouble due to the discontinuance of the tuberculin or to the silence treatment aided by the climate of Madeira? (after stopping the tuberculin I had three injections of antistreptococcus vaccine). My personal opinion is that if I had continued tuberculin I would not now be penning these lines.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

THE FASTING TREATMENT OF DIABETES.*

By E. I. SPRIGGS, M.D., F.R.C.P.,

DUFF HOUSE, BANFF, SCOTLAND.

I PROPOSE to give a brief account of our experience with the fasting method at Duff House. The treatment has not been in use long enough to justify anything like a statistical analysis. I shall therefore pick out those cases which are most instructive, both as regards the results obtained and the difficulties met with.

Fasting has been used in diabetes as a means of reducing the sugar in the urine ever since it was proposed by Naunyn. It has usually, however, been prescribed with much caution, in earlier days because it seemed unlikely that it would do good to deprive the subject of a wasting disease of food, and in later days with the idea, shown to be mistaken by various workers, that because abstinence from food causes a moderate acidosis in health, it would aggravate the more severe acidosis of diabetes. But in mild types, and especially in the obese, fasting has long been found useful. I may here relate one such case, which was under treatment before Dr. Allen's work was known to me.

CASE I.—Mild Glycosuria accompanying Hypoacidity, Ileal Stasis, and Obesity. (Case 277.)

The patient, a stout man of 41, sought relief for abdominal pain and distension of three years' standing, with nausea and giddiness for the last year. He was under treatment for ten weeks. On examination the gastric juice was very poor in both acid and pepsin, the ileum, caecum, and appendix were adherent, and there was marked ileal stasis. The blood pressure was 175 mm. Hg.

The urine was found to contain 6 to 12 grams a day of sugar, but no aceto-acetic acid or acetone. The blood contained 0.17 per cent. of sugar. On a diabetic diet, continued for six days, the sugar varied from 5 to 2 grams; aceto-acetic acid and acetone appeared in the urine. Such a diet was undesirable from the point of view of the gastro-intestinal symptoms, and was not well borne.

He was therefore advised to fast, with the object of getting rid of the sugar more quickly. After one day sugar was absent. For the next six days he took a diabetic diet of 1,600 calories. He was then tested with the following foods in turn—bread, potato, oatmeal, milk, pear, apple, banana, grapes, orange, and puddings made with flour, 40 grams a day of carbohydrate being given in each case. The urine remained free from sugar, but there was still aceto-acetic acid and acetone, though never enough to estimate. The diet was increased until he was taking 112 grams of carbohydrate a day, of which 46 was in bread, 46 in puddings, 15 in stewed fruit, and 5 in milk. With this the acid bodies disappeared from the urine, which remained sugar-free.

After reading Dr. Allen's writings and becoming convinced that not only glycosuria but also acidosis was benefited by longer periods of fasting we began to make trial of the method.

Outline of the Procedure.

Fasting is continued in bed until the urine has been sugar-free for twenty-four hours, unless there is some definite contraindication, such as nausea, vomiting, insomnia, or faintness. For the first two days of the fast nothing is given except a cup of tea with 10 c.cm. of 20 per cent. cream at breakfast and tea-time. After the first two days 150 c.cm. of clear meat broth is added at lunch and dinner-time. If acidosis is present after two days of fasting, alcohol may be allowed, 0.12 gram per kilogram of body weight being given in the form of whisky four times a day—at 11 a.m., 2 p.m., 5 p.m., and 8 p.m. In the cases described below no alcohol was used. When the urine has been sugar-free for twenty-four hours, 7.5 grams of carbohydrate is added in the form of vegetables which contain low percentages of carbohydrate. On the second day of feeding 30 c.cm. of cream is allowed with each cup of tea, and three eggs are added. On the third day of feeding, and on each alternate day subsequently, 5 grams of carbohydrate is added. Vegetables containing higher and higher percentages of carbohydrate are used, and finally porridge, oatcake, macaroni, bread, and fruit. The addition of carbohydrate is continued until sugar reappears or the tolerance reaches 3 grams of carbohydrate per kilogram. At the same time 15 grams of protein in

the form of meat and fish are added daily up to 1 gram per kilogram or, in certain cases, more. When the protein has reached the desired amount, fat is added at the rate of 25 grams daily until the patient stops losing weight, or is getting 40 calories per kilogram. If sugar at any time recurs in the urine, the patient is fasted again until the urine is sugar-free for twenty-four hours. The diet is then resumed at the point where it was left off, but only half the amount of carbohydrate is given until the urine has been sugar-free for two weeks, after which the carbohydrate is increased at the rate of 5 grams per week.

The fasting part of the method is simple enough. The gradual increase of the food afterwards is not so easy, at all events in the more severe cases. Accurate diet lists and close daily supervision are required. We found that the figures given by Dr. Joslin for the carbohydrate content of the foodstuffs did not agree with those obtained in our laboratories for foods as served at table. No doubt the methods of preparation differ in different countries. My colleague, Dr. Pickering, constructed graduated tables of diet, therefore, based mainly upon the analyses of our own cooked foods, and these tables we hope to publish, as I believe they would be of use to the profession.

I will now describe five of the cases we have treated by this method, selected as representing different ages and varying degrees of severity.

In all the sugar in the urine was estimated gravimetrically, and that in the blood by Bang's method as described by S. W. Cole. With Bang's method the normal blood sugar is about 0.11 to 0.14 per cent. For beta-oxybutyric acid Kennaway's method was used, and for acetoacetic acid and acetone the Scott-Wilson method. In some cases Hurlley's method was used for acetoacetic acid alone. Ammonia was determined by Malfatti's method.

CASE II.—Mild Diabetes. (Case 331.)

The patient, a man of 67, who had done much hard and responsible work in different parts of the globe, had not felt so well for the last eight years. Loss of flesh and polyuria was noticed six months, and glycosuria three months ago. He was under treatment for six and a half weeks. On admission he complained of feeling dizzy and squeamish, and of pains and stiffness in the thighs. The arteries were moderately thickened, the blood pressure 130 mm. Hg. Moist râles were heard at the base of each lung.

The urine contained 49 grams of sugar and a trace of aceto-acetic acid. The blood contained 0.24 per cent. of sugar. On a diet containing 64 grams of carbohydrate the sugar sank to 10 grams. With a further reduction of carbohydrate to 25 grams less than a gram of sugar persisted in the urine, and the blood sugar was now reduced to 0.14 per cent., that is, to within normal limits.

On fasting the urine became free from sugar at once. Feeding was begun after two days, the amount of carbohydrate, protein, and fat being gradually increased until a total of 3,304 calories, containing 88 grams of carbohydrate, 123 grams of protein, and 261 grams of

Case 331.—Analyses by A. B. Weir, B.Sc.

In all charts: TR, Trace; AA, aceto-acetic acid and acetone; o, beta-oxybutyric acid; NH, percentage of total nitrogen as ammonia; NH₃, ammonia in grams. The thickest line is the sugar, when present. The curve of the carbohydrate in the food, which sometimes crosses that of the sugar, is a thinner line. The urine remained sugar-free throughout except that a trace appeared when the carbohydrate exceeded the above quantity. Aceto-acetic acid and acetone were absent and the blood sugar remained normal. All the symptoms were gone except the stiffness of the thighs, which with suitable massage improved greatly. The weight fell nearly 3½ lb.

This patient would probably have done well without

* A contribution to the discussion at the Royal Society of Medicine on May 16th, 1916, opened by Dr. O. F. F. Leyton.

fasting, according to earlier standards, but whereas, formerly, if sugar appeared in the urine he would have had to remain on a strict diet for a considerable time, he will now fast a day, and will then be able very soon to take again a diet containing a fair quantity of carbohydrate. In other words, he will be able to keep sugar-free with greater precision and comfort.

CASE III.—Mild Diabetes in an Aged Man with Hypertrophied Heart and High Blood Pressure. (Case 289.)

The patient was 79 years old. He had lived a vigorous open-air life, but had not restricted himself in any way as regards alcohol and tobacco. Thirst came on rapidly thirteen years ago, followed soon by aching and cramps in the limbs, which have persisted. He was under treatment for six and a half weeks.

He was stout, with thick arteries and an enlarged heart. The blood pressure varied from 184 to 225 mm. Hg.

The urine contained albumin varying from 0.5 to 1.5 parts per 1,000. There were traces only of acetoacetic acid and acetone. The sugar ranged from 20 to 40 grams; in ten days, on a strict diet, it sank to 8 grams.

We hesitated at first to deprive this patient of food on account of his age, and, as a tentative measure, kept him in bed one day, and allowed him two eggs only. On this day the sugar fell to 2 grams. The next three days he took a strict diet, and passed 3 to 6 grams a day. He then fasted two days, on the first of which there was a trace of sugar, on the second none. He was now very hungry, and we gave him a diet of 1,600 calories—that is, more food than the routine prescribes—with the result that a trace of sugar was present on three of the next five days, and on the other two an estimable quantity.

He therefore fasted two more days, becoming sugar-free again, and remaining so while the diet was gradually increased to 1,800 calories, including 64 grams of carbohydrate, 40 of which was in the form of white bread. A trace of sugar then appeared, but after that the urine became sugar-free without further fasting, and remained so during tests with bread, potato, oatmeal, and milk. The albumin diminished, and for the last week of his stay was below five parts per 1,000.

CASE IV.—Diabetes in a Young Man. (Case 301.)

The patient, aged 25, was wounded by shrapnel on active service five months before admission. During convalescence a dry mouth and thirst came on rapidly and the urine was found to contain 10 per cent. of sugar. Weakness and aching of the legs followed. He was rather thin with a clear skin.

The urine contained 174 grams of sugar, 0.8 of acetoacetic acid, and 0.1 of acetone; 6 per cent. of the total nitrogen was in the form of ammonia; 2 drachms of sodium bicarbonate rendered the urine alkaline in twenty-four hours.

Case 301.—Analyses by A. B. Weir, B.Sc.

With gradual restriction of carbohydrate the sugar sank in three weeks to 20 grams a day, the acetoacetic acid increasing a little—namely, to 1.6 grams.

A fast of one day did not clear the urine, and after an interval he fasted three days, the urine becoming sugar-free on the second. The diet was then gradually increased, and the tolerance tested for measured quantities of bread, potato, oatmeal, rice, apple, banana. From these 98 to 100 per cent. of the carbohydrate was assimilated, the largest amount of carbo-

hydrate taken in one day being 71 grams. On several occasions, when the amount of carbohydrate given touched the limit of tolerance, a little sugar appeared in the urine, but was always abolished by reducing the amount in the food.

The patient went away sugar-free, the symptoms having vanished and the weight increased by 10½ lb. He and his medical adviser were provided with a scheme of diet based on the analytical results obtained.

The three preceding cases (II, III, and IV) are examples of different types. They include patients of ages ranging from 25 to 79. They show that fasting for three days, and underfeeding for several days after, did not give rise to any harmful or distressing symptoms, and led to much improvement in the feeling and condition of the patients. The urine became free from sugar and acid bodies without delay, and remained so on a mere liberal diet than that taken before treatment.

I may add that repeated fasts have been used, under my direction, in diabetes complicated by phthisis, with excellent results.

In the two following cases, more severe in type, the treatment, though well borne by the patients, did not give such good results.

CASE V.—Moderately Severe Diabetes. (Case 337.)

The patient, aged 33, had lived in India for several years. While on active service in the Mesopotamian campaign, thirst, polyuria, and blurred vision came on suddenly, and the weight soon fell away. On examination, three months later, he was moderately thin, the pulse 112; blood pressure 164 mm. Hg.

On a diet similar to that taken before admission, which included about 20 grams of carbohydrate, the urine contained 83 grams of sugar, 2.2 of beta-oxybutyric acid and 0.6 of acetoacetic acid and acetone; 5 per cent. of the urinary nitrogen was in the form of ammonia. The blood contained 0.19 per cent. of sugar. With reduction of carbohydrate to 30 grams a day (in greens and milk), the protein in the food being kept constant, the blood sugar fell to 0.14 per cent., and that in the urine to 14 grams a day, with 1 gram of oxybutyric acid and 0.5 gram of acetoacetic acid and acetone.

He then fasted two days. There was a trace of sugar on the first day, none on the second. The blood sugar sank to 0.10 per cent. The diet was gradually raised in nine days to 2,000 calories, including 70 grams carbohydrate, without glycosuria. The acid bodies almost disappeared also, the total of the three being only 0.2 gram.

On giving more food, however, sugar appeared. A day's fast got rid of it, but it was not found possible this time to increase the food to the same extent as before, for sugar appeared and rose steadily even when no carbohydrate was taken except that in greens. Thinking that we might be giving some unsuitable form of protein we gave all the protein one day as fish and another as eggs, but the sugar continued to rise.

Ten days after the last fast the patient fasted again, this time for three days, the urine being sugar-free for the last two of them. The blood sugar was 0.12 per cent. Food was gradually added until, nineteen days after the last fasting day, a trace of sugar was found. At this time 2,200 calories, with 33 grams carbohydrate, was being taken. The blood sugar was 0.13 per cent.—that is, within normal limits.

The urine was again cleared by a two days' fast, the blood sugar falling to 0.10 per cent. The weight had now fallen 10 lb. in eight weeks, and the patient was desirous that we should spare him the long period of undernutrition and increase the food more quickly. He was then treated on former lines—that is, on a diabetic diet of sufficient heat value. The weight rose 11 lb., and the patient's sense of wellbeing and his energy rose with it, but sugar was present.

The chart (p. 843) shows well how glycosuria was postponed by making the addition of food very gradual. After the third fast it is seen that the increase of all the food-stuffs was much slower, but in each period of increasing food an estimable quantity of sugar occurred when the heat value reached the neighbourhood of 3,000 calories, which was 48 calories per kilogram. With 2,000 calories, giving 32 calories per kilogram, glycosuria was absent. The caloric value of the food—that is, the amount of protein and fat—appeared to have more effect in causing glycosuria than the amount of carbohydrate.

With the reduction in carbohydrate before the fasting the blood sugar fell to within normal limits, and the subsequent appearances of sugar in the urine were not accompanied by any obvious increase of that in the blood. But with the rise of urinary sugar at the end of the chart the blood sugar also rose. Foster suggests that glycosuria may be more difficult to control in patients without marked hyperglycaemia.

As regards acidosis, the graph shows that the first fast temporarily increased the oxybutyric acid, acetoacetic acid, acetone, and ammonia, but this effect was less with each succeeding fast.

The fall of oxybutyric acid as carbohydrate food increased after the first fast is well shown, the amount dropping nearly to zero in about ten days.

On reviewing the treatment it is possible that this patient would have done better if after the first fast a weekly fast of a single day had been given to re-establish tolerance for food, or if less fat had been given. As regards the tolerance for carbohydrate, that appeared to be lower after the later fasts than at the beginning. It got worse and not better.

It is premature to draw any conclusions adverse to the treatment from this case, for in some respects Dr. Allen's instructions were not rigorously followed. I have related the case in some detail because it was carefully observed, and because it illustrates the advantage, the difficulty, and the disadvantage of the method in a moderately acute and resistant case of diabetes.

The advantage is immediate and obvious. The urine is cleared of sugar to the satisfaction of the physician and the patient. The difficulty lies in keeping the increase of protein and carbohydrate and fat a gradual one, and at the same time resisting the natural desire of the patient to get enough to eat. The disadvantage in this case was that when the patient was on a maximum diet of, say, 2,200 calories, his capacity for work and ordinary life was greatly diminished. He did not feel fit enough to drive his car even short distances for pleasure. On a fuller strict diet, although passing some sugar, he can drive, and works a couple of hours at a book he is writing with ease and enjoyment.

Experience may show that a man lives longer if he is kept sugar-free even at the expense of his general nutrition. But, until we have evidence on that point, I am inclined to think that in treating a chronic disease it is of importance to maintain the patient in such a state of nutrition that he can work and can enjoy himself.

Case VI.—Severe Diabetes. (Case 338.)

The patient, aged 24, was on active service in France when he caught a bad cold, followed by bronchopneumonia, and was invalided home. After a month he was better, but felt run down, and on examination the urine was found to contain 9 per cent. of sugar. Before coming to us he had been kept for a time on a strict diet, and then fasted four days. The urine had become sugar-free and the diet had been gradually enlarged.

On admission he was drowsy and the breath smelt strongly of acetone. On a strict diet of 3,000 calories the urine contained 176 grams of sugar, 9 of aceto-acetic acid and acetone, and 38 grams of nitrogen. The blood contained 0.21 per cent. of sugar.

The patient's condition appeared serious, and sodium bicarbonate was given in milk up to 35 grams (1½ oz.) a day; this made the urine alkaline. A week after admission the temperature rose, and signs of bronchopneumonia developed. The acidosis became still more severe, aceto-acetic acid and acetone reaching 20 grams in the day. The urine became acid again, but was made alkaline by increasing the bicarbonate to 42 grams (1½ oz.) a day. The pneumonic signs disappeared, and in a little over two weeks after admission he was feeling well; the

aceto-acetic acid and acetone had fallen to 5 grams a day. He was still taking 35 to 42 grams of sodium bicarbonate daily. The blood sugar was now 0.17 per cent.

A week later a fast was begun. It was not complete in that for the first five days 16 oz. a day of milk was drunk, as the bicarbonate was given in milk. The fast was continued for ten days, for the last five days of which no milk was taken, but at the end of that time the urine was not free from sugar. The chart (p. 844) shows the gradual fall from 137 to 14 grams a day. The blood sugar came down to 0.14 per cent.—that is, to within normal limits.

The diacetic acid and acetone were reduced from 15 grams to 5 grams a day. Corresponding with this the bicarbonate was cut down to 7 grams (½ oz.) a day, the urine remaining alkaline. The acidosis was so much lessened that at the end of the fast no bicarbonate was needed for a fortnight, and then only half the quantity which had been needed before.

During the latter days of the fast the patient was extremely hungry and dreamed of food, but felt nevertheless better and clearer than he had for a long time. On gradually increasing the food to normal—that is, 40 calories per kilogram, without any carbohydrate except that in greens, the blood sugar rose

again to 0.21 per cent.; the glycosuria also increased, though not to its former level. The acid bodies were in much smaller quantity than they had previously been on a strict diet. The patient was up. He felt weak but was cheerful.

After an interval of nearly a month the patient undertook a second fast, which was continued for six days. This time the sugar sank to a low figure on the second day, and on the fifth there was none. A trace appeared on the sixth day, but the fast was, nevertheless, stopped, and sugar was absent on the succeeding days. Ten days after the fast he had reached 900 calories. The patient is still under treatment.

The graph shows that the percentage of blood sugar and the amount of ammonia in the urine both became normal. The oxybutyric acid, aceto-acetic acid, and acetone were also reduced rapidly to very small quantities.

I must not discuss the metabolic changes in detail to-day, but may point out that this patient was not only unable to use carbohydrate in the

food but was excreting a large quantity of sugar formed from his tissues and from the protein, and perhaps the fat in the food. Fasting had the effect of enabling him for the time being to burn all, or nearly all, of the sugar produced from his tissues. Further, as less sugar was passed out after he was fed, it had improved his capacity for burning sugar made out of protein or fat in the food, and greatly reduced his acidosis. How far the benefit will reach remains to be seen. It is certain, however, that in a case of this severity such a good effect on the disordered metabolism cannot be attained by any other means at our disposal at the present time.

It is clear, therefore, that a fast offers the quickest means of restoring, to a greater or less degree, the power of assimilating the sugar which is made in the body from the protein, and possibly the fat, of the tissues or the food. It must not be forgotten, however, that the power to use sugar made in the body may be restored in all but the most severe cases, though much more slowly, by a strict adherence to a diabetic diet. This point is of such great

Case 337.—Analyses by A. B. Weir, B.Sc.

importance, especially to those who have to go on working, that I will venture to take up your time further by giving

Case 338.—Analyses by A. B. Weir, B.Sc. E. Estimated separately March 24th to April 10th, also 17th-19th and 25th to May 2nd.

two examples of it, both in marked cases of diabetes, one with but little acidosis, and one with acidosis well established.

CASE VII.—Diabetes with Mild Acidosis treated by a Modified Strict Diet. (Case 134.)

The patient, aged 44, gave a family history of diabetes and phthisis. He worked several years in a tropical climate and had had dysentery. Nine years ago he was near to death for some weeks with an abscess in or above the liver, either dysenteric or secondary to a gangrenous appendix. After a slow recovery he remained in this country. For the past two or three years he has done hard and responsible work. Two months before admission thirst and polyuria came on suddenly and glycosuria was found.

On admission the urine contained 137 grams of sugar, 0.3 of aceto-acetic acid and a little acetone. The blood contained 0.26 per cent. of sugar. In the course of three weeks the carbohydrate in the food was diminished, and after that a strict diet was taken for a week. By cutting off carbohydrate gradually an increase of the acidosis was successfully avoided. A few grams of sugar, however, still persisted in the urine. Tests were then made to find out what carbohydrates were assimilated best; these showed very poor assimilative power except for apples. He went away at the end of two months, with about 5 grams of sugar per day in the urine. The symptoms had disappeared. There was great gain of vigour and an increase of weight of 5½ lb. The blood sugar on departure was 0.22 per cent. He was advised to keep to a strict diet, with an apple three times a week and two vegetable days a week. He did this conscientiously, with the result that the urine became sugar-free two months later and remained so.

A year after his first admission he returned to be "chemically overhauled." In the interval he had been working continuously. The urine was free from sugar. Aceto-acetic acid and acetone were present, but not enough to estimate. The blood sugar had become normal, 0.11 per cent. On adding small quantities of starches no sugar appeared, and in the course of three weeks

the carbohydrate was increased until a diet containing 81 grams carbohydrate, 96 of protein and 180 of fat was taken, yielding 2,400 calories. On this there was no sugar or acetone, and only a trace of aceto-acetic acid.

CASE VIII.—Diabetes with Marked Acidosis treated by a Modified Strict Diet. (Case 151.)

A man of 57 had had cramps in the legs for eighteen months, had lost over a stone, and felt ill. Polyuria was noticed and sugar discovered. On admission the blood pressure was 180, the liver enlarged. The urine contained 172 grams of sugar, 5 grams of aceto acetic acid, and 0.2 gram of acetone. The blood contained 0.37 per cent. of sugar. The patient bore restriction of carbohydrate badly at first, but became accustomed to it later. The sugar did not fall, however, below 60 to 100 grams a day after three weeks on a strict diet. The aceto-acetic acid, though rising at first, settled to a level of about 2 grams a day. Tests with various carbohydrates showed that 76 per cent. of the sugar in milk was assimilated, rather less from apples, and

Case 151.—Analyses by A. J. Leigh, B.Sc.

very little from the other forms of starch and sugar tried. After two months the symptoms were almost gone, the general health much improved, and the weight heavier. There was still, however, 50 to 80 grams of sugar a day in the urine and 2 to 3 of aceto-acetic acid. The blood sugar varied from 0.30 to 0.35 per cent.

He was advised to keep three absolutely strict days a week and to take an allowance of a pint of milk and an apple on the other days.

After a year's work with careful adherence to the diet prescribed the urine is free from sugar, diacetic acid, and acetone, and the patient in good health. Small quantities of other carbohydrates are now being added to the diet.

Both these patients took food of adequate caloric value, were well nourished, and able to work steadily and efficiently, the evidence of the disease becoming less all the time. I bring them forward to show that cases which were in some respects intractable in a two months' observation did well as a result of keeping steadily to their diet, after an investigation had been made to find what food was suitable for them.

CONCLUSIONS.

Much time will be needed before a reasoned judgement on the fasting method can be given. At the present time I may summarize our observations as follows:

Fasting, up to several days, was well borne by cases of mild and severe diabetes of ages ranging from 24 to 79.

The urine was made free from sugar, the blood sugar was reduced, and acidosis greatly diminished.

All the patients felt better for the fast.

In most cases the food could be increased gradually, without glycosuria, until a more liberal diet was being taken than before treatment.

The rapid abolition of sugar had an excellent mental effect. It shortened tedious treatment, and enabled more time to be given to finding out what food should be taken and in what quantity.

The gradual increase of food after the fast calls for skilled dietetic arrangements and careful daily attention. It is not so easy as an ordinary strict diabetic diet. It is useless, however, except in the mildest cases, to increase the food quickly after the fast, as sugar returns at once.

During the gradual increase of food the patient is under-nourished. In severe cases courage and endurance are called for on his part, as it may be necessary to keep him so short of food that he is inefficient.

Regular estimation of the blood sugar should be made.

In some cases of diabetes as good an effect may be

attained, though much more slowly, without fasting and subnutrition, with its risk of depression and weakness, provided the patient is willing to keep permanently to the diet which has been found by careful testing to be suitable to his case.

At the present time the doctor, in order to decide as to the best treatment in severe cases, must judge of the temperament of the patient. To some it is purgatory to be continually having to think about tests and figures. These will do best with definite allowances in an otherwise rigid diet. In others the disadvantages of a half-starved condition must be balanced against the mental effect of the absence of sugar. We do not yet know whether the progress of the disease is arrested by this method in cases in which it would not be arrested by a permanent adherence to a rigid, though plentiful, diet.

For all milder cases, indeed for the majority of all cases, Dr. Allen's procedure offers great advantages. We have evidence enough that such patients, though not cured, may be freed from the signs and symptoms of their complaint. This beneficent result has been attained through the extraordinarily wide and painstaking researches of Dr. Allen on animals. None but those whose lot it has been to attempt to make researches and to describe them when made, can appreciate the perseverance and the labour which have gone to the making of Dr. Allen's book and subsequent writings. I am sure we rejoice with him that he has been the means of enabling a clear step forward to be made in the treatment of a distressing complaint.

A SIMPLE SYSTEM OF SKELETON SPLINTING.

By C. MAX PAGE, M.S., F.R.C.S.,
CAPTAIN R.A.M.C.(S.R.).

THE value of skeleton splinting in the treatment of gunshot fractures has been generally recognized during the present war. Lieutenant-Colonel Robert Jones¹ was responsible for the introduction of this type of splint, and for the extension of its use in our army medical service. I have previously described² how the aluminium stapled strips contained in the field fracture box may be used to make splints of this kind. These stapled strips, however, having been designed to form imitations of the classical solid splints, do not afford an ideal method of coupling lengths for the formation of skeleton frames. The joints effected by the method are not mechanically sound, and hinge formation is not possible. I propose here to describe a system of coupling which has not these defects, and, moreover, one in which the process can be easily and rapidly carried out.

MATERIAL AVAILABLE.

Aluminium strips, $\frac{1}{2}$ in. by $\frac{3}{4}$ in., form splints which are easily malleable by hand, and are sufficiently stable for field purposes. In the case of the larger splints for the lower extremity, however, the material is not always sufficiently rigid for prolonged treatment. Further, at the present time the supply of aluminium for surgical purposes is limited.

There are similar objections to the use of copper and zinc alloys; annealed mild steel appears to be the most satisfactory material available. Annealed steel, $\frac{1}{2}$ in. by $\frac{3}{4}$ in., has much greater vertical rigidity than aluminium, and though it has more lateral spring, it is sufficiently malleable for practical use.

I will therefore describe the system of coupling in relation to the use of annealed mild steel.

Specification of Material.

The stock material consists of five-foot lengths of annealed mild steel $\frac{1}{2}$ in. by $\frac{3}{4}$ in. This material is of standard type, and is sold by any iron merchant. The strips are drilled throughout their length at 1 in. intervals with holes of $\frac{1}{8}$ in. diameter. The holes must be accurately distanced throughout the strips.

Split steel rivets $\frac{1}{2}$ in. by $\frac{3}{4}$ in. are required to couple the

various lengths after they have been bent to form the splint required.

Tools Required.

A *cramp* of the new pattern supplied in the field fracture box; this serves to hold the strips while they are being bent in the direction of their vertical section.

A *screw wrench* with slots $\frac{1}{2}$ in. by $\frac{3}{4}$ in. cut in the jaws $\frac{1}{2}$ in. from the shaft (Fig. 1). This wrench holds the strips and supplies the leverage for bending them; it also serves as a hammer.

A *hacksaw* for cutting the material.

A *triangular file* for trimming the ends or for cutting the strips if the saw be not available.

A pair of "bell" pliers with a screwdriver end on one handle; the latter is used to spread the rivets, and the pliers to crush them after they are in place (Fig. 2).

FIG. 1.—Screw wrench with $\frac{1}{2}$ in. by $\frac{3}{4}$ in. slots cut in jaws, holding a strip of splinting.

Method of Cutting Strips.

To divide the mild steel strips at the required level the material is cut half through with a hacksaw, and then snapped off by hand. In using the hacksaw, the tool should only bear by its own weight lest the blade be broken.

The triangular file can be used for the same purpose, but is not as neat or quick to work with.

Method of Bending Strips.

The strips can be moulded on the flat by hand; if a sharp angular bend is required, the screw wrench should be used.

To bend the material on edge, the strip is fitted into the cramp, the screw wrench is fitted home on the strip close to the cramp, and then used to lever the material to the desired angle (Fig. 1). A right angle is the sharpest bend which can be effected in this way, unless the material is previously heated, and even then there is a tendency for the strip to buckle; this tendency is overcome by removing the strip from the cramp in the course of the process and beating out the angle on an anvil. If the part of the strip to be bent is first heated in the flame of a Primus stove, the procedure is much facilitated.

Method of Coupling Strips.

Strips are united in their long axis by passing split rivets through opposed holes. The rivets are then spread with the screwdriver end of the pliers and finally crushed or hammered out (Fig. 2). Three rivets give a firm longitudinal junction.

FIG. 2.—Side view of two lengths of splinting, showing (1) rivet in place, (2) spread, (3) crushed down.

A hinge joint is formed by a single rivet.

A rigid joint at any angle is made by strutting such a hinge joint (see Fig. 3, d).

Completion of Splint for Application (Pads and Slings).

The only part of these splints which requires formal padding is the crutch in those of the modified Thomas's pattern (shown in Fig. 3 at A, in Figs. 6 and 11, and in Fig. 12 at c). This is best effected by winding tow evenly on to the part of the frame which forms the crutch; the tow is then fixed by bandaging firmly over it. For treating compound fractures in the early stage, it is desirable to cover the pad so formed with impermeable material. I have found a length of bicycle inner tube the most satisfactory; this should be rolled on to the splint in the same way as a rubber cricket bat handle is put on; it is then fixed at either extremity with a strip of adhesive plaster.

In splints for the upper extremity the crutch may often be sufficiently padded by passing a length of stout drainage tube on to that part of the frame.

In general, the splints are completed with slings. These are best made from some adaptable but inextensible material, such as old linen. In certain cases troughs of

perforated zinc sheeting may be substituted for the fabric slings. No padding is ever needed between a linen sling and the skin.

TYPE SPLINTS FOR THE LOWER EXTREMITY.

1. Modified Thomas's Knee Splint.

Two full lengths (5 ft. each) of splinting and one of about 20 in. are required (Fig. 3). The crutch, A, which should

FIG. 3.—Modified Thomas's knee splint. A, Crutch; B, notch in stirrup extremity; C, prop; D, strut fixing prop.

measure about 15 in., is bent in the central part of one full-length strip. This involves two right angle bends on edge. The crutch should not form simply the section of a circle; it should be moulded as shown in Fig. 4. The stirrup extremity, B, is readily moulded by hand in the form

FIG. 4.—Diagram of proper shape of a thigh crutch for the right side, seen from above.

shown in the figure from the remaining long strip. These two parts are then united by rivets to give a splint of the required length; for an average case there should be an overlap of 9 in. on the inner side and 7 in. on the outer (supposing the crutch to have been centrally placed); this gives the necessary obliquity to the crutch. Three rivets on each side give a firm junction. The prop, C, is then bent and attached to the splint by a rivet and strut, D, about 18 in. from its lower extremity; the base of the prop should measure at least 10 in. if the splint is to be used for transport.

An arch may be placed between the side limbs of this splint, about the level of the knee-joint if particular rigidity is required. A footpiece, as shown in Figs. 6 and 9, may be fitted when necessary. The splint may be flexed at the knee-joint in those cases in which straight extension does not produce good alignment of the fragments of the femur; under these circumstances it will be found necessary to bend the side members of each section separately before riveting them together.

This splint, completed with linen slings, is well suited for the treatment of many cases of fractured femur as well as injuries of the knee-joint and tibia. It should be slung in the ordinary way from four points (as shown in Fig. 7), the prop only coming into action during transport.

A strap passed across the front of the thigh keeps the crutch in place during movement; another one should be passed in front of the tibia just below the knee-joint; this should only be tightened when the patient is rolled on his side; it will be found that the flat surface of the side members of the splint adapts itself closely to the surface of the thigh, thus giving excellent lateral support to the limb in the circumstances.

The fixed extension obtained by means of this splint is effected by a canvas strap passed around the notch in the stirrup of the splint and the spreader.

2. Hodgen's Splint.

This type (Fig. 5) is made in the same way as the previous pattern, except that an arch, C, is substituted for a

FIG. 5.—Hodgen's splint. A, Anterior thigh arch; B, stirrup notch; C, knee arch.

prop, and the side members are slightly flexed at the level of the knee-joint.

3. Skeleton Double Incline Splint.

This splint (Fig. 6) is made from the same elements as the modified Thomas's knee splint. The side members of

FIG. 6.—Skeleton double incline splint. A, Knee stirrup; B shows bend in lower side members of the splint; C, foot arch and props.

the crutch section are bent in and joined with two rivets to form a 4-in. stirrup, A. The side members of the stirrup section are bent to an angle of about 135 degrees at B, before being riveted to the upper part.

In the type illustrated in the figure (6) a combined foot-piece and prop C is bent from a length of about 24 in., and is riveted and strutted in the required position. If no control of the foot is required, a simple prop may be substituted.

This splint has been designed for use in cases in which both the tibia and femur are broken. It allows extension to be applied independently to each bone. The splint is shown in use in Fig. 7.

The extension appliance for the femur may be of the adhesive variety, or when insufficient whole skin is avail-

FIG. 7.—Skeleton double incline splint applied. The splint is suspended by four points from a beam. Linen slings support the limb, and fixed extension is applied separately to thigh and leg. The crutch has been padded as described in the text.

able for the purpose a collar of plaster-of-Paris may be moulded on to the condyles of the femur. A strap or elastic extension is passed from the transverse a round the spreader of the extension appliance (Fig. 7).

In general the method of application of the splint is the same as for a Thomas's knee splint; the strap in front of the thigh to keep the crutch to its work is essential. In cases where the tibia and fibula are broken the footpiece comes into use. This may be completed with fabric slings of zinc sheeting; when necessary the foot may be suspended as shown in Fig. 8.

In some cases suspension by a single strip of fabric stuck to the sole of the foot with glue (Heusner's) may be an advantage; this is especially the case when there is paralytic foot-drop. The footpiece should then be set rather higher up on the splint than the level of the sole of the foot in order to give the necessary control of the tendency of the foot to become plantar flexed.

FIG. 8.—Diagram to show method of suspending the foot with an adhesive strap from the foot arch.

4. Knee Splint (Jones).

The backbone (Fig. 10) is made from two lengths of about 42 in. riveted together at a few points and bent to shape by hand. One thickness of the splinting is not sufficiently rigid. Thigh, calf, and foot pieces of suitable dimensions made from zinc sheeting are then riveted on to the backbone. The zinc sheeting can be reinforced, if necessary, by riveting stout cardboard, linoleum, or similar material on to it. To more closely copy the original pattern of the splint, the footpiece may be made from two short lengths of the splinting.

FIG. 9.—Tibia splint. A, Stirrup notch; B, foot arch hinged and strutted on to frame; C, thigh arch similarly attached.

two pieces of 24 in. and 20 in. respectively.

The main frame is bent from the full length with a notched stirrup A, and slight angles at the level of the knee-joint. The footpiece and prop B (24 in.) is made as for the double incline splint. The upper arch and props C are similarly riveted and strutted on. The splint is best completed by fabric slings.

For any case in which the fibula is intact no extension will be required. If both bones are broken and there is any tendency to overlap, fixed extension is effected as follows: A light collar of plaster-of-Paris is moulded round the leg at the level of the tubercle of the tibia; the side members of the splint are then fixed to this collar by another encircling plaster bandage, or else two side straps may be passed up from the collar and attached to the sides of the arch C. Counter fixation having been thus secured, traction is made through a strap passed around the notch in the stirrup at A and the spreader of the extension attachment.

6. A Stump Tractor (after Makins).

This (Fig. 11) is made in the same way as a modified Thomas's knee splint, but it will naturally be shorter.

An apparatus for thigh stumps is made from one full length of splinting; a prop of the type shown in the figure is added, it should be of such a height that while the hip-joint is not materially flexed the lower surface of the stump is kept clear of the bed.

Extension is made from an adhesive attachment to the skin through a circular or cross-shaped spreader. The adhesive should be applied to the greatest possible surface of skin.

FIG. 11.—Stump tractor.

application and use of these splints which may be referred to here.

In cases of fractured femur, in the absence of wounds in the leg, a simple adhesive extension (Buck's) is the most satisfactory.

The apparatus consists of two side straps of 2-in. adhesive plaster continuous below over the spreader. The spreader should be slightly wider than the measurement between the outer surfaces of the two malleoli. The side straps are lined with lint in their lower six inches.

After shaving the limb, the side straps are applied; they should adhere to the upper two-thirds of the leg and

5. Tibia Splint.

This (Fig. 9) is made from one full length of the splinting, and from

FIG. 10.—Jones's knee splint. The backbone is made from two lengths of splinting lightly riveted together; thigh, calf, and foot pieces are made from perforated zinc sheeting.

Application of Extension Apparatus.

There are certain practical considerations in relation to the general

to as much of the skin of the thigh as circumstances permit. The side straps are kept to their work by a carefully applied open wove bandage, extending from 3 in. above the level of the malleoli to the upper extremity of the plaster. Circumferential bands of adhesive plaster are never necessary, and their edges are always liable to cause pressure sores as the extension slips slightly in the course of treatment.

In the place of adhesive plaster strips of fine calico may be used, a soluble glue being employed as the adhesive medium. Heusner's glue is a satisfactory preparation of this kind, and is made of cheap ingredients; its composition is as follows:

Resin	50 grams.
Venice turpentine	5 grams.
Methylated spirits	50 c.cm.
Benzine	25 c.cm.

After the skin has been shaved the glue is painted on the required area and allowed to become "tacky"; the fabric is then pressed on to it and a bandage applied over the whole. No further application of the glue should be made. Extensions put on in this way hold very firmly for a few weeks; slight vesication sometimes occurs at the margins of the surfaces of application.

If multiple wounds prevent the use of an adhesive extension, the pull must be taken from a more limited area. In such circumstances plaster-of-Paris is the best medium. It can be applied as an ankle or knee-cap. An ankle is made by binding one or two muslin plaster bandages directly around the ankle and incorporating the tails of the extension in it. The skin is greased and if necessary shaved. The bandage should extend well down on the os calcis and forward on the instep to within an inch of the base of the toes. The ankle is moulded on to the prominent points about the ankle, and allowed to harden before any extension is applied.

The knee-cap takes its main purchase from the condyles of the femur, particularly the inner one. A plaster bandage is applied evenly to the knee-joint area, extending from one inch above the upper border of the patella to the level of the joint line. As it dries the plaster is laterally pressed and so moulded firmly on to and above the prominences of the two condyles of the femur; the grooves so formed should be held till the casing becomes firm.

These two procedures have the disadvantage that they fix the joints covered, but they allow very powerful extension to be made during the necessary period. In my experience most leather anklets if used under pressure cause sores in a few days, or even during the period of transport from clearing station to base.

Control of the Foot.

In many cases of fractured femur, when a limb has been put up on a Thomas's or similar splint, the patient is able to fully dorsiflex his foot voluntarily. If he is encouraged to do this regularly, no fixation of the foot need be practised.

In other cases, especially when there has been some injury to the external popliteal nerve, the position of foot-drop tends to become permanent. In these circumstances a foot arch should be attached to the splint as shown in Figs. 6 and 9, a bandage stretched tautly across the arch will then serve to keep the foot up. In some cases suspension from the heel with a strip of adhesive may be resorted to, as shown in Fig. 8. An alternative method is to apply a strip of fine calico to the surface of the sole of the foot with soluble glue, and to suspend from this.

Undue external rotation of the foot and leg in cases of fracture does not often occur in limbs which are put up properly extended.

The correct position of the foot is determined by comparison with the sound side, it being borne in mind that the foot rolls out naturally a little in the passive supine position.

Avoidance of Pressure Sores.

Pressure sores are, and should be, the great bugbears of the surgeon treating fractures of the lower extremity. In cases treated on splints of the above described types they may appear in the following situations:

(a) *Over the Area Exposed to the Pressure of the Crutch.*—Theoretically, a sore from crutch pressure should develop over the tuber ischii. Not infrequently,

however, the skin in the genito-crural area may be eroded, and sometimes that in the ischio-sacral angle. Such sores should not appear if the patient is rolled on his side daily and the skin under and around the crutch cleaned with spirit, gently massaged, and then powdered. If wound discharges gain access to the area, even more frequent attention is necessary.

FIG. 12.—Bent arm splint. A, Hand arch which is used for a hand grip or for the attachment of an extension strap in cases of fracture of the forearm; B, notch for extension strap in cases of fractured humerus; C, axillary crutch hinged by single rivets on to main frame; D, reinforcing arch which may be omitted.

avoided by bending out the splint at the level implicated, and not by the insertion of a pad.

(c) *In Relation to Extension Attachments.*—Adhesive extensions applied as described above will not damage the skin; on the other hand, transverse bands of adhesive strapping at the level of the tubercle of the tibia and about the ankle are prolific sources of sores.

Plaster-of-Paris appliances gain a very positive hold of the limb, and if a very powerful extension is applied sores may result, but they are not frequent if the plaster casing is carefully moulded to the limb and allowed to harden properly before any pull is applied. Such extensions should be changed if the limb shrinks much in size from the subsidence of swelling or from muscle wasting.

TYPE SPLINTS FOR UPPER EXTREMITY.

Modified Straight Thomas's Arm Splint.

This splint is a small replica of the lower extremity

FIG. 13.—Bent arm splint diagrammatically applied for a case of fractured humerus. The axillary crutch is padded by a length of drainage tubing. F, Extension strap for a case of fractured humerus.

venient level in the elbow region in order to reinforce the splint as a whole. The crutch is padded with rubber tubing and internal slings applied to the frame to complete the splint for use.

For cases of fracture of the humerus when light extension may be required, the hand is fixed to a pad on the frame either at A or E. Extension is then made by a strap or a few turns of rubber bandage passing over the front of

the first few days after the application of a splint before the skin has adapted itself to the new situation. Great care should therefore be taken in sending patients from a clearing station to the base to minimize any necessary pressure.

(b) *Over Lateral Prominences of the Limb.*—The side members of the splint may press on the limb at the knee or the ankle; such a possibility should be

at the level implicated,

the forearm and around notch B. The splint is shown diagrammatically applied in Fig. 13. When the splint is used for fractures of the forearm, extension is obtained by fixing the upper arm to the posterior part of the frame and extending from A through an adhesive attachment to the wrist and hand. The pivoting of the crutch (C) allows of easy temporary or permanent abduction of the arm.

Hinged Elbow Splint.

The frame is made (Fig. 14) from two upper side pieces of about 7 in. length; the forearm and hand arch require a length of about 40 in. The single rivet hinge joint at the elbow is fixed at the required angle by one or two struts. The splint is completed with zinc troughs, as shown in figure.

FIG. 14.—Hinged elbow splint strutted at a right angle.

Jones's Elbow Splint.

The backbone of this splint is made (Fig. 15) of two lengths of about 26 in., riveted together at a few points. Two troughs are added, as shown in the figure. This splint can be bent so as to be used as an anterior splint if necessary.

FIG. 15.—Jones's elbow splint.

Wrist Splint.

The forearm and hand frame (Fig. 16) is made for average cases from a length of 36 in. The upper arm arch and side pieces are bent from a length of about 12 in. The latter is hinged and strutted on to the main frame. If it is desired to put the hand up in extension the frame is bent at B, as shown.

Slings are arranged to hold the upper arm and forearm. The wrist can be held extended by a single narrow band across the palm, if it is desired to leave the fingers free.

FIG. 16.—Skeleton of forearm and wrist splint.

CONCLUDING NOTES.

It should be understood that the measurements and details given for all the above described splints are for average cases. Modifications in size and design will often be necessary, and are readily carried out.

If aluminium strips be used on the same system the ease with which angular bends can be carried out on edge with this material will make many of the above described single rivet and strut joints unnecessary.

The splints can always be reinforced, if exceptional rigidity is required, by the addition of arches or by riveting extra lengths on to the main frame.

MEDICAL inspection in Boston under the supervision of the School Board came into force on November 22nd, 1915. A report by Dr. W. H. Devine, Director of Medical Inspection, on the physical examination of children in the public schools from December 1st, 1915, to April 1st, 1916, states that 49,777 pupils were examined; of these, 34,792 were found to present defects. The conditions classed as "defects" included defective nasal breathing, hypertrophied tonsils, bad teeth, defective palate, cervical glands, pulmonary disease (24 tuberculous, 456 non-tuberculous), heart disease (organic 725, functional 888), nervous disease, chorea, joint and bone disease (tuberculous 49, non-tuberculous 877), skin disease, rickets, malnutrition, and mental deficiency (243). The number of cardiac cases, according to Dr. Devine, suggests that the prevention of heart disease offers a great field for research in prophylactic medicine.

A "CAGE" SPLINT FOR FRACTURES OF THE HUMERUS.

BY CAPTAIN E. M. COWELL, R.A.M.C.(S.R.).

The splints that experience has shown to be of value in the treatment of fractures of the humerus at a casualty clearing station are the following:

1. *Surgeon-General Sir Anthony Bowlby's splint*, shaped like the letter P lying on its side, and composed of a rubber-covered iron loop made to pass over the shoulder and attached to a wooden bar for the support of the forearm. This splint is useful for fractures of the upper part of the shaft, but is difficult to keep in position.

2. *Clarke's F-shaped splint* is made with a long horizontal bar supporting the forearm, and an additional piece of wood hinged on to the internal vertical part to give support posteriorly. This splint is extremely useful where there is great loss of tissue and the bone is severely comminuted. Irrigation can be readily performed, the wound can be easily inspected at frequent intervals without disturbing the patient, and where the onset of gas gangrene is expected the wounds, unless posterior, can be exposed to the air or sunlight if desired.

3. *Lieutenant-Colonel Robert Jones's Modified Thomas's Arm Splint*.—Neither the straight nor special bent form has been used owing to unsuitability for travelling.

4. *Captain Max Page's Aluminium Splint*.—This closely resembles Sir Anthony Bowlby's iron and wood splint, but is less rigid.

5. *Lieutenant-Colonel G. M. Giles's Metal Splint*.—This splint was recently described,¹ and presents one important feature also seen in the splint described below—namely, a firm metal loop passing over the acromion, fastened under the opposite axilla, and thus forming a fixed point from which extension is made. The splint, however, is made from materials not at hand in a clearing station, and takes "less than an hour" to manufacture.

The Cage Splint.

Having tested the above-mentioned splints by a considerable experience, I have for several months past used a splint of my own device, which, in addition to the advantages of the several splints mentioned above, presents many of its own. It is very light, and supports the upper limb completely, allowing ready access to the wounds. In most cases the patient can be evacuated as a sitting case, and moves about without pain or discomfort. The splint can be put together in a few minutes by an intelligent orderly from the aluminium splinting, abundance of which is always available. It is useful for all fractures of the humerus, more especially for those of the lower two-thirds of the shaft, also for severe fractures of the elbow-joint and extensive wounds of the upper part of the forearm.

The details of construction of the splint can be readily seen by reference to the figure. A bar of aluminium splinting, 3 feet long (12 "divisions") is bent with the fingers to follow the outer curve of the shoulder, arm, and elbow. In an average patient this will bring the eighth rivet (counting from above) immediately beneath the olecranon. From this point, using the groove provided on the top of the fracture box for the purpose, a rectangular bend is made to carry the rest of the bar forwards along the ulnar border of the forearm. This curve is made away from the middle line of the body, and therefore fits a right or left arm as required.

The splint is completed by two short pieces, 9 in. long, connected by transverse pieces of aluminium tape 12 in. long, which are passed between the third, fourth, and fifth rivets of the long bar, and thus form a cage which wraps round and encloses the arm. Similar pieces, 12 and 10 in.

Splint applied; dressings not shown.

¹ Described and figured in the *Memorandum on the Treatment of Injuries in War*, 1915.

respectively, are connected to the last foot of the bar, and form a cage for the forearm.

In the *Royal Army Medical Corps Journal* of March, 1916, there is a description of this splint as originally devised, without the forearm attachment or "cage." With this cage it is found that extension is easier to apply, and that there is greater rigidity and comfort to the patient.

Application.

The application of the splint is simple, and takes but a few minutes. In cases of compound fractures, the wounds having been carefully dealt with under an anaesthetic and drainage having been established, etc., the dressings are applied in such a way that a sufficient clean area is maintained, and at the same time the gauze in immediate contact with the wounds can be changed through the "windows" of the cage, with the minimum amount of disturbance.

The shoulder-piece is fixed over a sufficiently thick pad of wool, and kept in position by tapes passing under the opposite axilla. Next, the upper cage is fitted closely round the arm, and the whole bandaged. The forearm is finally put up in any desired position. If the musculo-spiral nerve is damaged, the hand and wrist may be maintained in a dorsiflexed position by suitable adjustment of the lower cage.

In simple fractures care must be taken to preserve sufficient extension at the elbow.

The question of the position of the forearm with relation to the trunk must be considered. The patient is undoubtedly more comfortable for his journey with the forearm supported across the front of the chest, but in the majority of cases the lower fragment is rotated at right angles to the upper. The best position must be decided for each case individually and controlled by skiagrams.

The splint is approved by Colonel Cuthbert Wallace, A.M.S., and is used extensively by my colleague Lieutenant A. C. Bryson.

Conclusion.

In conclusion, I should like to point out the importance of the system of aluminium splinting to those surgeons in hospital and private practice who are not yet acquainted with it. No hospital splint room will in future be completely equipped without a supply of the material, and, moreover, speaking from the experience of many of my friends and myself, few surgeons will in future care to be without the aluminium splinting material for their private work.

THE INHIBITORY ACTION OF SALIVA ON GROWTH OF THE MENINGOCOCCUS.

BY

LIEUTENANT-COLONEL M. H. GORDON, R.A.M.C.

In March, 1915, when teaching some pupils to recognize colonies of the meningococcus in plate cultures made from material taken from the nasopharynx, it was thought that a simple method of demonstrating the first step in the identification of this micro-organism would be to mix a suspension of it with saliva, and to make a plate culture from the mixture.

This, accordingly, was done. It was found, however, that whereas numerous colonies of salivary bacteria, chiefly streptococci, developed, no colonies of the meningococcus appeared. A plate culture made at the same time from the meningococcus suspension yielded numerous colonies of this micro-organism. Clearly, then, in this instance, the saliva had inhibited growth of the meningococcus.

As Captain Colebrook of St. Mary's Hospital had recently shown me his discovery of the inhibiting power exercised upon the growth of the meningococcus by a Gram-positive coccus which he had found to replace the meningococcus in the nasopharynx of a carrier when the latter became "free," it occurred to me that possibly the present phenomenon might be an instance of a similar action. Equally, however, it might be due to some inhibitory

effect of the saliva itself, apart from any bacteria contained by it. The following experiments were made for the purpose of clearing the matter up.

EXPERIMENT I.

About one cubic centimetre of normal saliva was collected in a sterile test tube. This was then well mixed with a few drops of a broth suspension of meningococcus made by richly inoculating a broth tube from a twenty-four hours' nasagar culture. Droplets of this mixture were spread on two plates of nasagar and incubated. At the same time a control plate was inoculated from the broth suspension of the meningococcus.

Result.—Both plates from the mixture showed profuse growth of salivary bacteria, but no meningococcus colonies. As the control plate yielded a good crop of colonies of this micro-organism, it was plain that the saliva had inhibited growth of the meningococcus.

EXPERIMENT II.

Saliva was smeared across a plate of nasagar in a band about a centimetre in diameter. Meningococcus suspension was smeared across in a similar band at right angles to the first. On incubation it was found that meningococcus appeared in sections of its band where the saliva had not been spread, but where the bands crossed only salivary bacteria grew.

EXPERIMENT III.

Meningococcus suspension was smeared all over the surface of a nasagar plate. A drop of saliva was then smeared over half of it. Meningococcus colonies only came up on the half of the plate where saliva had not been smeared.

EXPERIMENT IV.

A single drop of saliva was distributed over three nasagar plates in gradually diminishing proportion. A loopful of meningococcus suspension was then distributed over each plate in turn, care being taken to sow the same amount on all. The result was as follows:

The fine dots represent colonies of salivary bacteria; the heavy dots represent colonies of meningococcus.

The first plate showed colonies of salivary bacteria only. The second plate showed the majority of the same and two colonies of the meningococcus. The third plate showed more colonies of the meningococcus and fewer colonies of the salivary bacteria. The colonies of the meningococcus, therefore, were in inverse proportion to those of the salivary bacteria.

EXPERIMENT V.

This experiment was made in order to ascertain in what dilution saliva loses the property of inhibiting growth of the meningococcus.

A cubic centimetre of saliva was submitted to a series of decimal dilutions. One-tenth of a cubic centimetre, first of saliva, then of each dilution in turn, was taken up in a series of capillary pipettes. An equal amount of meningococcus suspension was next drawn into each pipette and the contents well mixed, expelled on to a nasagar slope, and the latter incubated.

Result.

Amount of Saliva Sown on Tube.	Growth of Meningococcus.
0.1 c.cm.	<i>Nil.</i>
0.01 c.cm.	Two colonies.
0.001 c.cm.	Confluent over lower half of tube.
0.0001 c.cm.	Confluent.
Control of meningococcus suspension only	Confluent.

This experiment showed that the inhibition became diminished when the saliva was diluted one-hundredfold and over.

EXPERIMENT VI.—Saliva from "Carriers."

The preceding five experiments were made with saliva from normal individuals. The present test was made with saliva from "carriers." Through the courtesy of Captains Douglas and Colebrook, samples of saliva were obtained from six carriers who were at that time under treatment at St. Mary's Hospital. Although these six persons one and all harboured the meningococcus—or a micro-organism closely resembling it—in their nasopharynx; their saliva not only failed to show

the meningococcus, but was found to inhibit growth of this micro-organism in the same way as samples of saliva from normal persons had been found to do.

EXPERIMENT VII.

Nasal mucus was obtained from three normal persons and tested in the same way against meningococci, with the result that, in contrast to saliva, it was found to have no inhibitory action on the growth of the meningococcus. The specimens of nasal mucus tested grew colonies of staphylococcus and of *M. catarrhalis* which did not impede development of the meningococcus.

EXPERIMENT VIII.—Effect of Heating Saliva.

A sample of saliva was divided into two portions. One was heated to 55° C. for half an hour. Both were then tested with regard to their capacity of inhibiting growth of the meningococcus.

Result.—Whereas the unheated saliva inhibited growth of the meningococcus as in previous experiments, the heated saliva was found to be completely void of this property. The plates from this heated saliva showed a profuse and pure culture of the meningococcus.

Heating, therefore, destroys the antimeningococcal action of saliva. It also destroys the salivary bacteria.

SUMMARY.

The experiments made up to this point demonstrated the following facts: Normal human saliva inhibits growth of the meningococcus on a nasagar plate. Saliva from carriers has the same effect. Nasal mucus from normal people has no such action. The inhibitory effect of saliva corresponds with multiplication of the bacteria indigenous to it. This anti-meningococcal property of saliva is destroyed by heating the saliva to 55° C.; so are the salivary bacteria.

EXPERIMENT IX.—Effect of Centrifuging Saliva.

Five cubic centimetres of saliva were centrifuged for four hours on a water centrifuge. The top and bottom layers were then compared with the uncentrifuged saliva in regard to inhibitory action on growth of the meningococcus.

Result.—The uncentrifuged saliva showed as before well-marked antimeningococcal action and a good crop of colonies of salivary bacteria. The bottom layer of the centrifuged saliva showed complete inhibition of the meningococcus and a confluent growth of salivary bacteria. The top layer, on the other hand, had lost the majority of its bacteria, and also to a great extent its inhibitory action upon growth of the meningococcus.

This experiment was repeated and confirmed on three separate occasions, using a high velocity electric centrifuge. It was found also that if, in spite of being centrifuged, the saliva contained many salivary bacteria in its upper layer, this portion still exerted an inhibitory action on growth of the meningococcus.

EXPERIMENT X.—Comparison of Raw with Centrifuged Saliva.

A suspension of meningococcus was made in broth. A series of capillary pipettes were then calibrated to hold the same volume of fluid. In three of these pipettes in succession one volume of raw saliva was mixed with one volume, two volumes, and three volumes respectively of meningococcus suspension and plated.

This was then repeated with centrifuged saliva. The result was as follows:

	Growth of Meningococcus.
Raw saliva:	
1 vol. + 1 vol. meningococcus suspension ...	<i>Nil.</i>
1 vol. + 2 vols. " " ...	<i>Nil.</i>
1 vol. + 3 vols. " " ...	<i>Nil.</i>
Centrifuged saliva:	
1 vol. + 1 vol. meningococcus suspension ...	Excellent.
1 vol. + 2 vols. " " ...	Excellent.
1 vol. + 3 vols. " " ...	Excellent.

While one unit of raw saliva inhibited growth of three times its bulk of meningococcus suspension, the same volume of saliva, after being centrifuged, failed to inhibit growth in an equal volume of suspension. A culture showed that the number of living meningococci in one volume of the suspension used in this experiment was approximately five hundred:

EXPERIMENT XI.—Comparison of the Effect of Blood Serum, Saliva, and Centrifuged Saliva respectively from the Same Person.

In this experiment equal quantities of the three materials in question were brought in contact with diminishing amounts of a meningococcus suspension, and, after admixture, plated. The results were as follows:

Dilution of Meningococcus Suspension.	Blood Serum.	Raw Saliva.	Raw Saliva after being Centrifuged for 3½ hours.
Undiluted	+++	-	+++
1:10	++	-	+
1:100	++	-	(one colony)
1:1,000	+	-	-
1:10,000	+	-	-
1:100,000	+	-	-

+ = Growth of meningococcus.

The blood serum, as was to be expected, encouraged rather than inhibited growth of the meningococcus. The volume of suspension here used ($\frac{1}{50}$ c.cm.) contained approximately 24 million living meningococci—about 1,000 million per c.cm. The raw saliva completely inhibited an equal volume of this suspension. After being centrifuged, however, this inhibitory power of the saliva was reduced between 10 and 100 times—that is, a cubic centimetre of the saliva would now have inhibited between 10 and 100 million meningococci instead of over 1,000 million as before.

All of the cultures in the above experiment in which the meningococcus did not appear showed a good growth of salivary bacteria.

SUMMARY.

Up to this point, then, the investigation had shown that saliva inhibits growth of the meningococcus only so long as it contains in living condition its own natural flora. When the indigenous bacteria have been destroyed by heat, or removed by centrifuge, this inhibitory power is lost or diminished according as they are destroyed or greatly reduced in number.

Cultures made from Saliva.

In order to test this provisional conclusion and to take the matter a step further, the investigation was now continued with cultures made from saliva.

EXPERIMENT XII.

A flask containing 250 c.cm. of ordinary peptone broth was inoculated with two loopfuls of normal saliva and incubated at 37° C. In the course of twenty-four hours or so the broth became turbid from the growth of *Streptococcus salivarius* and other salivary cocci.

The contents of the flask were divided into four portions. These were treated as follows:

1. Was not interfered with.
2. Was heated to 55° C. for thirty minutes.
3. Was centrifuged for three hours.
4. Was passed through a Berkefeld filter.

A portion of each was mixed with an equal amount of suspension of meningococcus in a capillary tube, and then distributed over a plate of nasagar. The result given by these plates, after incubation, was as follows:

No.	Material.	Result of Test.
1	Broth culture from saliva; 24 hours' growth at 37° C.	No growth of meningococcus; profuse growth of salivary streptococci.
2	Ditto, after being heated to 55° C. for 30 minutes	Pure and copious growth of meningococcus.
3	Ditto, after been centrifuged for 3 hours	No growth of meningococcus; profuse growth of streptococci.
4	Ditto, after passage through Berkefeld filter	Pure and copious growth of meningococcus.

The broth culture from saliva, therefore, was found to inhibit growth of meningococcus in just the same way that saliva itself does. This action of the broth culture disappears when the bacteria contained by it are destroyed by heat, or when they are removed by a Berkefeld filter. The centrifuge failed to remove them in this experiment, with the result that the inhibitory action of the broth culture on the meningococci was retained.

EXPERIMENT XIII.

In the following experiment a sample of saliva that had stood for forty-eight hours at room temperature was compared with two broth cultures therefrom (of twenty-four and forty-eight

hours' growth respectively) as regards their capacity of inhibiting growth of the meningococcus.

This test was made quantitatively. Decimal dilutions from each of the materials tested were brought in contact with equal amounts of a suspension of meningococcus in capillary pipettes, and after thorough admixture the contents of each pipette were plated on nasagar.

The results, as regards growth of the meningococcus, were as follows:

Material.	Undiluted.	1:10.	1:100.	1:1,000.	1:10,000.
1. Saliva kept for 48 hours at room temperature	-	-	+	+	+
2. Broth culture therefrom of 48 hours' growth	-	-	+	+	+
3. Ditto of 24 hours' growth	-	-	-	+	+

+ = Growth of meningococcus.

From this it appears that the twenty-four hours old broth culture was more active in inhibiting the meningococcus than either of the other two materials tested.

EXPERIMENT XIV.

Three broth cultures, each from a single colony of the predominant micro-organisms present in the twenty-four hours old broth culture tested in the last experiment, were examined in the same way, with the following result. All of these cultures were of forty-eight hours' growth at 37° C.

Material.	Undiluted.	1:10.	1:100.	1:1,000.	1:10,000.
Colony 1: <i>Streptococcus brevis</i>	-	+	+	+	+
Colony 2: <i>Streptococcus longus</i>	-	+	+	+	+
Colony 3: <i>Staphylococcus</i>	+	+	+	+	+

+ = Growth of meningococcus.

From this it appears (1) that the staphylococcus had no inhibitory action on the meningococcus; (2) that both the streptococci held up growth of this micro-organism when undiluted, but lost this property when their broth culture underwent a tenfold dilution. These streptococci, therefore, were much less potent than the broth culture from which they had been isolated.

GENERAL SUMMARY.

1. Normal saliva inhibits growth of the meningococcus upon solid artificial culture medium (nasagar).

2. Saliva from carriers has a similar action.

3. Nasal mucus from normal persons has no such inhibitory effect on the growth of meningococcus.

4. A quantitative experiment showed that fresh saliva does not entirely lose this inhibitory influence when diluted a hundred-fold.

5. So pronounced is the antagonism of saliva to growth of the meningococcus in culture, that in a given experiment a volume of broth suspension containing living meningococci at the rate approximately of 1,000 million per c.cm. was prevented from growing by admixture with an equal volume of fresh saliva.

6. This antimeningococcal action of saliva is due to its living bacteria.

7. A young broth culture from saliva is at least as efficacious as fresh saliva in antimeningococcal action.

8. This effect is due to the living and multiplying bodies of the bacteria in the broth. When they have been separated off by a Berkefeld filter, or killed by heat, the broth has lost its antimeningococcal power.

9. The inhibitory action of saliva appears to be chiefly due to mixed salivary streptococci. Pure cultures of the predominant streptococci, when tested individually, were found to exert comparatively slight inhibitory influence on the growth of meningococcus.

10. These observations demonstrate the practical importance of avoiding contamination with saliva when swabbing the nasopharynx of suspected carriers of the meningococcus.

THE BEHAVIOUR OF HYPOCHLORITES ON INTRAVENOUS INJECTION AND THEIR ACTION ON BLOOD SERUM.*

BY

H. D. DAKIN, D.Sc.

HYPOCHLORITE solutions containing variable amounts of free hypochlorous acid have been employed fairly extensively for the local treatment of infected wounds. Recently one of these solutions, "eusol," introduced by Professor Lorrain Smith and his co-workers, has been administered by intravenous injection with apparently successful results in cases of septicaemia and toxæmia.¹ It was of interest, therefore, to endeavour to determine some of the factors conditioning the action of this solution and related substances.

The object of the following communication is to describe certain experiments which appear to prove that hypochlorite solutions when injected intravenously in quantities similar to those employed for therapeutic purposes cannot exert any appreciable direct germicidal action. It should be noted that, with the exception of certain experiments by Cordova,² in which eusol given intravenously was stated to be capable of protecting rabbits from lethal doses of staphylococci and *B. capsulatus*, no direct curative effects have been claimed in cases of septicaemia in which organisms were isolated from the blood. Lorrain Smith, Ritchie, and Rettie state that "the method of intravenous injection may give favourable results in cases of general septic infection in the field, gangrene, tetanus, and other kindred conditions characterized by toxæmia."

1. Quantitative Relations.

Eusol has been used for intravenous injection in man in doses ranging from 60 c.cm. to 100 c.cm. An average full dose may be taken to be 100 c.cm., corresponding to 0.27 gram of hypochlorous acid. This amount is at once diluted with four or five litres of blood, so that the possible concentration of hypochlorous acid, assuming that no decomposition of the drug by the blood occurs, is not more than 50 to 65 mg. of hypochlorous acid per litre. Even if this concentration persisted temporarily, which will shortly be shown not to be the case, it is much below the concentration of hypochlorite at which active direct action is observed, when tested against organisms such as *B. coli* or staphylococci suspended in blood, or even in serum.

Direct experiments in which *B. coli* or staphylococci were mixed with sterile rabbit serum or plasma, and then 70 mg. per litre of hypochlorous acid in the form of eusol added, showed no marked diminution in the number of organisms in the course of two hours when compared with a control experiment in which no hypochlorous acid was added. Precisely similar results were obtained when the hypochlorous acid solution was injected intravenously into rabbits, and the serum taken before and after the injection was tested against *B. coli* *in vitro*. The following are typical results. The concentration of hypochlorous acid added was 70 mg. per litre in all cases.

Mixture.	Organisms per drop, 15 c.cm., at end of two hours.
1. Normal serum + <i>B. coli</i>	780
" " + <i>B. coli</i> + HClO	640
2. Normal serum + <i>B. coli</i>	1120
" " + <i>B. coli</i> + HClO	1280
3. Normal serum + <i>B. coli</i>	1640
Serum after injection HClO + <i>B. coli</i>	1760

The changes are in no case significant. Miss Chick³ has already shown that normal rabbit serum has practically no action on *B. coli* during the first few hours of action. The above experiments followed the technique described in Miss Chick's paper.

2. Fate of Hypochlorites on Intravenous Injection. Hypochlorous acid or its salts exert their known anti-

* The work here referred to was done with the assistance of a grant from the Medical Research Committee. The experiments were made in the laboratories of the Committee's Department of Biochemistry and Pharmacology. I am indebted to Dr. H. H. Dale, F.R.S., for much helpful advice and for facilitating my work in every way possible.

septic action on account of the active chlorine contained in them. This active chlorine may occur in two forms: that present as unchanged hypochlorite, and chlorine loosely bound to amino compounds, including proteins. Chlorine in both of these forms is able to liberate iodine from an acidified solution of potassium iodide, and hence may be easily detected. The antiseptic value of the chlorine loosely bound to amino compounds, in "chloramine" form, probably varies as the ease with which it can be detached so as to permit of union with other substances, including bacterial protoplasm. But hypochlorites can combine with a variety of substances by reactions of a different kind from that just mentioned. Thus, for example, the chlorine may become attached to carbon atoms present in proteins and other substances, and then loses its power of liberating iodine from potassium iodide, and confers no germicidal properties on the product. Furthermore, it is probable that direct reduction of hypochlorites to chloride may occur in the body, for this is a common reaction *in vitro*. Thus it is seen that hypochlorites may be decomposed and lose their germicidal properties by a variety of reactions. Changes of this nature apparently occur with great rapidity when hypochlorous acid or its salts are injected intravenously, for a much greater quantity of "eusol" per kilo of body weight than is used therapeutically may be injected intravenously into animals without the appearance of a detectable trace of active chlorine in the plasma or serum.

The following is a typical experiment. Under ether anaesthesia cannulae were placed in the carotid artery and femoral vein of a rabbit weighing 1,820 grams. Eusol of about half-strength (1 c.cm. = 1.3 mg. hypochlorous acid) was injected into the vein, and almost immediately afterwards blood was drawn from the artery into citrate solution, rapidly centrifuged, and the plasma tested as promptly as possible for active chlorine by adding potassium iodide, acetic acid, and excess of dilute starch paste. Control experiments showed that the citrate did not interfere with the reaction; 7 c.cm. of the eusol were injected fairly rapidly, and then the first sample of blood was withdrawn. Further samples of blood were taken after each additional injection of 2 c.cm. of eusol. Although haemolysis was detectable in all samples of blood, and was very marked in the later ones, no trace of active chlorine was found in the plasma obtained after the injection of 19 c.cm. of the hypochlorite solution, and only a doubtful reaction was obtained after further additions which finally killed the animal.

The volume of blood in the rabbit used in this experiment may be taken as approximately 125 c.cm., so that it is calculated that at least 200 mg. of hypochlorous acid may be added to each litre of circulating blood before any detectable trace of active chlorine appears in the plasma. This amount is more than three times the therapeutic dose. It may be noted incidentally that the minimal addition of hypochlorous acid to blood serum that will produce a positive reaction for active chlorine confers no added germicidal properties.

It might be suggested that in the foregoing experiment active chlorine could not be detected in the blood plasma on account of its being taken up by the cells. But special experiments showed that blood serum from rabbits and sheep required the addition of from 35 to 80 mg. of hypochlorous acid per litre before any active chlorine persists. Finally, it may be noted that if circulating or drawn blood is mixed with an amount of hypochlorous acid just sufficient to yield a plasma or serum giving a definite positive reaction for active chlorine, the latter rapidly disappears in the course of a short space of time.

From the foregoing experiments it appears in the highest degree improbable that any direct germicidal effects can be ascribed to hypochlorous acid or its salts when injected intravenously in the prescribed therapeutic doses.

3. Other Effects of Hypochlorites when given Intravenously.

When hypochlorite solutions are injected intravenously into rabbits a certain amount of haemolysis is observed even with doses as low as 1.5 c.cm. of eusol = 4 mg. of hypochlorous acid per kilo of body weight. With larger doses the haemolysis becomes more intense and the

coagulability of the blood becomes diminished.* When lethal doses of hypochlorite preparations or chloramine-T are given intravenously a marked increase in the pericardial fluid and oedema of the lungs is commonly observed. It appears that in large doses the substances act as definite endothelial poisons.

Since the experiments already referred to appear to prove that hypochlorite preparations given intravenously can exert no appreciable direct germicidal action, it

appeared conceivable that the favourable clinical results stated to follow their employment might be due to an indirect action in stimulating the production of antibodies. Thus far I have only had the opportunity of investigating the effects of hypochlorites given intravenously on the antitrypsin of the blood. The results seem of interest since Wright and others have suggested that antitrypsin plays an important part in the normal antibacterial properties of blood. Whether eusol or other hypochlorite preparations act as a stimulus for the production of other non-specific antibacterial and antitoxic substances is a question that requires further investigation.

For the experiments on the effect of hypochlorite given intravenously on the antitryptic action of the blood I enjoyed the co-operation of Dr. G. S. Walpole (and his assistant). An exceptionally precise method devised by him was employed, the details of which will be published shortly. The method essentially consists in the estimation by means of the dipping refractometer of the products of tryptic digestion, resulting from the interaction of constant quantities of trypsin and casein in the presence of varying amounts of blood serum. I am much indebted to Dr. Walpole for permission to make use of his method and results.

It was found that when small amounts of hypochlorite, either in the form of eusol or neutral sodium hypochlorite, are injected intravenously into rabbits, a fall is observed in the antitryptic action of blood serum taken immediately after the injection. But if another sample is taken twenty-four hours after the injection, it is commonly found that recovery in antitryptic action has proceeded to a point significantly in excess of the original value before hypochlorite was given. A typical example is shown in Chart I, in which the actual inhibition of tryptic digestion due to antitrypsin, and expressed in scale units of the refractometer, is plotted against the varying amounts of

which, for uniformity, are reckoned in milligrams of total nitrogen. The curve marked I represents the initial antitryptic action of the blood serum; that marked II the antitryptic action of the blood serum taken immediately after the injection of 5 c.cm. of eusol (= 14 mg. of hypochlorous acid) into the ear vein of the rabbit, which weighed 1,940 grams; and that marked III, the antitryptic action of the blood serum taken twenty-four hours after the injection.

CHART 1.—Showing reduction in antitryptic action of blood after injection of eusol, followed by increase above normal. I, Before injection; II, immediately after; III, twenty-four hours after.

tion of the way in which the active mass of the antiseptic may become rapidly diminished. In the case of both eusol and neutral sodium hypochlorite a curious fact was observed—namely, that a small amount of serum may bring about the disappearance of more active chlorine in a given time than will larger amounts of the same serum. This somewhat paradoxical reaction, which was independently observed by Dr. Harden, is best illustrated in the form of a chart showing the disappearance of active chlorine

CHART 2.—Showing greater disappearance of active chlorine from hypochlorite solution when treated with small amounts of serum than with large.

Similar effects were found to follow the injection of comparable amounts of sodium hypochlorite. The action of hypochlorites in causing a primary fall in the antitryptic action of the blood serum, followed by a secondary increase, is shared by many other substances.

4. The Action of Hypochlorites and of Chloramine-T on Blood Serum.

The rate of decomposition of hypochlorites by blood serum is a question of some importance in connexion with the local treatment of infected wounds, since the results afford some indication

of the way in which the active mass of the antiseptic may become rapidly diminished. In the case of both eusol and neutral sodium hypochlorite a curious fact was observed—namely, that a small amount of serum may bring about the disappearance of more active chlorine in a given time than will larger amounts of the same serum. This somewhat paradoxical reaction, which was independently observed by Dr. Harden, is best illustrated in the form of a chart showing the disappearance of active chlorine titratable with potassium iodide and sodium thio-sulphate, when a constant volume of hypochlorite is mixed with varying amounts of serum, and allowed to stand for thirty minutes at 20°. Similar results were obtained when the reaction was allowed to continue for a longer period. The typical results shown in Chart 2 were obtained by mixing 5 c.cm. of neutral hypochlorite containing 12.6 mg. of hypochlorous acid with varying amounts of sheep serum.

The explanation of this curious action of small amounts of serum on hypochlorite is to be found, I believe, along

the following lines. When the mass of the protein in the blood serum is relatively small compared to that of the hypochlorite the amount of chlorine taken up per molecule of protein is large, and the product becomes unstable and is readily hydrolyzed. This hydrolysis has the effect of liberating from the protein more amino-acid complexes, which can react with additional hypochlorite. Now Langheld has shown that amino-acids react with hypochlorites to form the sodium salts of mono- and di-chloramino-acids, and it is now known that these

* It has been stated that only eusol can be injected with safety, and that sodium hypochlorite must not be used. I have been unable to detect any significant difference between the effects of eusol and sodium hypochlorite prepared according to the formula given in the BRITISH MEDICAL JOURNAL, August 28th, 1915.

substances decompose spontaneously to give aldehydes or nitriles respectively, with liberation of carbon dioxide, while the chlorine is converted into inactive chloride.

I have observed that when small amounts of serum are acted on by relatively large amounts of hypochlorite, both gas production and aldehyde formation are much more pronounced than when the relative mass of serum is large. The fact harmonizes with the suggested explanation of the reaction between hypochlorites and serum. When the mass of serum is large in relation to the hypochlorite, it appears that the smaller amount of chlorine taken up by the protein does not confer on the product such instability as is seen in the case of more highly chlorinated substance. Chloramine-T, when added to serum, does not react like hypochlorite, but is decomposed to a smaller extent, varying directly with the relative mass of serum.

The above experiments are of a preliminary character, and it is hoped that some of the practical questions arising from them may be more closely investigated.

LOCALIZATION BY X RAYS AND STEREOSCOPY.

*Localization by X Rays and Stereoscopy*¹ is the title of a book by Sir J. MACKENZIE DAVIDSON which is published at an opportune time, seeing that the exact localization of foreign bodies within the human body is of such vital importance when so many wounded have to be dealt with accurately and with rapidity. Many time-saving methods of localization have been devised during the past eighteen months, mostly based on Davidson's original cross-thread method; few, if any, of these are quite so accurate. The stereoscopic method, also a discovery of the author, has not been, and is not, used so extensively as it should be. The simplicity of technique in the taking of such radiographs, the theory, and the way to apply the results are all well set out in this work, which, after dealing with the x-ray tube and secondary radiations and protection, describes in detail the use of stereoscopic radiographs. The last chapter, and one to which the author directs especial attention, is on the precise localization of foreign bodies in the eye and the orbit. If anything was wanting in the previous chapters to convince the reader of the accuracy possible in localization, this last chapter would supply that want, for in dealing with foreign bodies in those situations Davidson's method may be said to stand alone, its simplicity and accuracy being little short of marvellous.

On p. 22 will be found a description of a new x-ray couch which for simplicity of design, for adaptability to war work at the front, for ease and cheapness of construction, and for efficiency in doing what it is meant to do, will be hard to beat. Accompanying this is a very ingenious screen instrument which, when used with this couch or others of similar design, will enable the operator to read off on a scale the depth of a foreign body under a marked skin spot. In advocating stereoscopy attention is drawn to "the misleading single picture." With a knowledge of what is going on at the present time, with much of the war work being done by unskilled and even untaught x-ray operators, and with surgeons inexperienced in radiography, greater stress might well have been laid on this point. If the author had suggested that for a surgeon to act on the showings of a single radiograph when searching for a bullet was almost criminal, he might not have been going too far. The illustrations are excellent and an

important feature. Many diagrams help materially in the understanding of the x-ray descriptions, and at the end are a number of very beautiful reduced stereoscopic radiograms which can be viewed with one of the small, cheap stereoscopes so much in vogue. Whilst the expert in radiography can learn much that is of value from this publication, it is nevertheless of even more value to the surgeon, and especially to those surgeons who at the present time are attached to the army.

MEDICAL ETHNOLOGY.

Medical Ethnology,² by Dr. WOODRUFF, will interest students of anthropology and possibly also those of tropical medicine. The work was begun, the author tells us in the preface, as a revision of the first edition of *The Effects of Tropical Light on White Men*, but it was necessary to change the title because so many other factors besides pigmentation have entered into the discussion of the reasons for the differences between the present races and sub-races of men.

The subjects discussed in the twenty chapters include the effects of light on man, the question of pigmentation, actino-therapy, the cause of the extinction of migrants, ethnic psychology, etc. One thing the work brings out very clearly is the slender basis on which rests the hope that the white man will ever be able to inhabit the tropics—that is to say, to live there for good, breeding and propagating his species, even when all the diseases have been eradicated from them. Dr. Woodruff gives a good example of the mania amongst some people to deny that climate can affect any one. "The most notorious case was that of Civil Service Commissioner Washburn, who stated that the climate was not harmful if one was moral and sober, and that if he did break down recovery was possible there. Within a few months he himself collapsed and had to go away to get well." Similar cases can easily be quoted from British colonies, one example that is often mentioned being the sad end of a man who was trying to get other people's leave cut down, but before he had progressed far in his endeavour was himself removed by death. The advocates of the white man for the tropics seem to forget all about neurasthenia, irritability of temper, and loss of memory, or evidently do not consider them as diseases. These are, however, the very things that finish off so many people and render them unfit for further efforts in a hot climate. Make the tropics healthy by all means, so that the constant stream of migrants to them may have a chance of returning home again fit and well, but do not delude white people into the belief that if disease is stamped out they can make a permanent home there. In writing his book Dr. Woodruff has quoted largely from the literature, and incidentally has perpetuated many of the mistakes to be found in it—for example, the part on heat exhaustion, on p. 136, is hopelessly involved, and even distinctly misleading. Again, we cannot agree with him in all he says as regards light as compared with heat in producing symptoms. Statements also, such as that cases of chronic malaria have been cured without quinine by a five-minute dose of x rays to the enlarged spleen, would have been better omitted. The question of why certain races are found in some parts of the world and not in others is, however, a fascinating one, and a perusal of Dr. Woodruff's book will give the reader plenty of food for thought.

NOTES ON BOOKS.

READERS of the *BRITISH MEDICAL JOURNAL* will have studied with profit and amusement the articles on the *Minor Horrors of War* written by the Master of Christ's College, Cambridge. The articles have been collected into two volumes, of which the first was reviewed in our issue of April 17th, 1915. The second series, entitled *More Minor Horrors*,³ contains fourteen chapters, of which ten have already appeared in this *JOURNAL*. The book gives very readable accounts of such pests as cockroaches, the bot-fly, the mosquito, the biscuit weevil (so familiar to readers of Clark Russell's nautical novels), the fig-moth, the stable-fly, rats, and the field-mouse. There are

¹*Medical Ethnology*. By O. E. Woodruff, A.M., M.D. London: W. Heinemann. 1916. (Med. 8vo, pp. 328. 10s. net.)

²*More Minor Horrors*. By A. E. Shipley, Sc.D., Hon. Sc.D., Princeton, F.R.S. London: Smith, Elder, and Co. 1916. (Cr. 8vo, pp. 177; 49 figures. (Paper, 1s. 6d. net; cloth, 2s. net.)

¹*Localization by X Rays and Stereoscopy*. By Sir J. Mackenzie Davidson, M.B., C.M.Aberd. London: H. K. Lewis and Co., Ltd. 1916. (Roy. 8vo, pp. 83; 26 plates, 61 figures. 7s. 6d. net.)

numerous excellent illustrations; the book is written in most attractive style, and should have a wide popularity and sale.

The second edition of Dr. BARCLAY'S short textbook on *Elementary Anatomy and Physiology*,⁴ is meant for junior students, nurses, and teachers. It contains short sketches of such subjects as biology, embryology, comparative anatomy, and haemolysis. It is written in conversational style, and from the popular point of view, and is full of facts and information, and also of the general deductions to be drawn therefrom. The brief table of contents given above shows that Dr. Barclay covers a vast amount of ground in the volume; as he says in the preface, he holds that "a good macroscopic view of a wide area is better than a microscopic knowledge of many disjointed points." How far the inexpert reader will be able to master some of the subjects reviewed, and admirably reviewed, in the newly-added chapters of this textbook is a matter that only experience can decide. The text is well written, and the illustrations have been generally well chosen.

As a globe-trotter Sir FREDERICK TREVES has few competitors. A dozen years ago he went round the world sight-seeing, and "did" the Mediterranean and Red Sea, India, Burma and Ceylon, China, Japan, and America. The impressions of this delightful journey he published in 1905 in a volume entitled *The Other Side of the Lantern*, which has now been republished in a cheap and popular form.⁵ There is a moderate amount of the guide-book about Sir Frederick's work, there are a few pages of history, a few purple patches of rhetoric. For the rest he shows himself an admirable guide and interpreter for the man in the street; his faithful pen always maintains the same level of interest, his eye is quick to seize the salient points of what it views, and the itinerary he followed was carefully chosen to include the best known sights in every continent. The volume is excellently got up and illustrated, a marvel of cheapness. It should command a wide audience of readers.

⁴ *Lectures on Elementary Anatomy and Physiology*. By H. Clifford Barclay, M.D., Ch., F.R.C.S.E., M.R.C.S., L.R.C.P., Major R.A.M.C. Second edition. London: Baillière, Tindall, and Cox. 1915. (Demy 8vo, pp. 290; 57 figures. 6s. net.)
⁵ *The Other Side of the Lantern*. By Sir F. Treves, Bt., G.C.V.O., C.R., LL.D. London, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1916. (Demy 8vo, pp. 438; 8 illustrations. 2s. 6d. net.)

GOAT'S MILK.

We are interested to learn that the guardians of St. Marylebone have begun the establishment of a flock of goats to yield milk for the younger children in their schools. They have, it is stated, obtained six goats, and it may be presumed that if the experiment is successful the scheme will be extended; in this way something may be done towards increasing the popularity of goat's milk in this country, where at present it is very little used. The late Dr. Vivian Poore took a great interest in the use of goat's milk, and for some years before his death most of the milk consumed in his house at Andover was obtained from a few goats. To the objection that the milk often had a disagreeable flavour, he replied that this could be completely obviated if the he-goat was not allowed to run with the nannies during the time they were in milk.

Less than twenty-five years ago Professor Nocard, in speaking of the 130,000 goats and kids which at that time were brought into Paris every spring for slaughter in the shambles of La Vilette, said that amongst all these animals the meat inspectors had never found a single case of tuberculosis. In that statement lies the essence of the argument in favour of goat's milk as a substitute for cow's milk. Despite all the efforts of legislators, the danger of infection through the milk of diseased cows still exists; but goats, if not actually immune, are very refractory to the attacks of the tubercle bacillus. It is a curious fact, however, that in spite of its manifold advantages, goat's milk has never become really popular in these islands, although in many other countries it is a common article of diet, and in some parts of France and Switzerland the goat often takes the place of the wet nurse, to the satisfaction of all

concerned. In the memoirs of Madame Héritte-Viardet, niece of Manuel Garcia, the inventor of the laryngoscope, we find the author recording her indebtedness to a couple of goats which furnished milk for her little son during a voyage from England to the Cape, which in those days (1863) was no light undertaking, particularly for an infant. She writes:

My little boy had been born a short time before our departure, and we were obliged to make special arrangements for him during the voyage. At the last moment the wet-nurse refused to go, and, to the indignation of my relations, I decided to take a goat (or rather two goats in case one got ill) in her place. The French consul at Southampton, our place of embarkation, procured the animals for me and they were kept on deck in a railed-off place, and milked by the cook twice a day. One morning there was not a drop of milk. The sailors had milked the goats for their own benefit, and I was obliged to have a padlock put on the enclosure. For some days all went well; then suddenly one of the goats was taken ill and her milk left her. The other luckily continued to thrive. There was a young married woman on board with a baby and a wet-nurse. The latter lost her milk, and my goat had to feed both children. How thankful I felt that I had not listened to my family.

For some years past a movement has been on foot to popularize the milk of "the poor man's cow," and at least two societies—the National Goat Club and the British Goat Society—have been formed for the purpose of making it better known throughout the British Isles. At the Children's Welfare Exhibition, held at Olympia a couple of years ago, a model goat farm was exhibited by a lady who has made a special study of the subject. Her own experience had convinced Mrs. Lacy-Hulbert that goat's milk is not only superior to cow's, but is an excellent substitute for human milk, and that whilst the endowment of every man with "three acres and a cow" may be the dream of idealists there is no reason why even the poorest cottager should not possess a goat which would supply his family with pure whole milk, such as it might be impossible for him to buy in many country places, even if he had the money. Once the initial expense of purchase has been met, a goat, when circumstances are favourable, may cost very little to keep, as a considerable part of its food may consist of garden waste or of what the animal itself may find in its browsings along the roadside and hedges. Many goats thrive well when stall-fed, but this, of course, costs a good deal more money. The animal can be kept in health if it has a clean, dry, and well-ventilated shed to serve as a stable and a small yard or enclosure in which it can take occasional exercise. A goat, in fact, if it is hand-fed, does not require more space than a St. Bernard dog; and, if well-treated, may yield as much as 4 to 5 pints of milk a day, or even more. The milk is believed to be more easily digested than cow's milk, the curd being more soluble and the fat in finer emulsion. The goat will not touch dirty food and is far cleaner in its person and habits than a cow; its milk need not be boiled or pasteurized unless it has to be kept in hot weather. The characteristic odour sometimes emitted by goat's milk when it has been left standing may be avoided by scrupulous attention to cleanliness by the precaution already mentioned.

The most recent analysis of goat's milk we have been able to find is in Neumann's letters to a young practitioner on the treatment of children's diseases, edited by Oberwarth (*Ueber die Behandlung der Kinderkrankheiten*, 1913). The figures for human and cow's milk are quoted from Langstein and Meyer, but the source of those for goat's milk is not stated. We have added the figures for Alpine goats given by Crepin, who has laid stress on the variations in the composition of the milk of different breeds of goats.

		Proteins.	Fat.	Sugar.	Ash.
Human	1.2	4.0	6 to 7	0.18
Cow	3.4	3.4	3 to 4	0.75
Goat	German	3.67	4.3	3.6	0.8
	Alpine	2.3	3.1	4.1	0.7

In some varieties of wild goats the percentage of fat may be as high as 4.8 on the average, with an extreme upward limit of 8.7. Crepin is of opinion—and Losage, from his experience in Paris, appears to agree with him—

The British Goat Society issues a monthly circular (price 31), which can be obtained from Mr. H. S. Holmes Pegler, honorary secretary, Coombe Bury House, Kingston Hill, Surrey. The society is holding a goat show on July 11th in connexion with the Richmond dog show on the same day.

that the objection which has been raised to goat's milk that it is too rich does not apply to stall-fed goats.

The quantity of milk yielded by a goat varies very much, and is influenced by the breed and by other conditions. The yield seems to be usually greater after the second kidding than after the first. The estimates of the average yield are very far from consistent. Neumann speaks of 4 litres (about 7 pints), and considers that even with this high yield goat's milk is not cheaper than cow's milk if, as he would appear to mean, the animal is stall-fed. The advantages he recognizes are that if a goat is kept by the consumer it is possible always to have fresh milk, and that the risk of tuberculosis is small. Lesage concludes that the advantages of goat's milk are (1) that a goat eats about one-sixth of the quantity of food required by a milk cow; (ii) that for nine or ten months it yields 3 to 5 litres of milk, which can be taken uncooked; (iii) that goats are very seldom affected by tuberculosis, since of 3,000 killed at the Lyons slaughterhouse only 5 were tuberculous; and (iv) that the fat being in very fine emulsion is easily digested. On the other side of the account must be put the liability of the goat to carry the infection of undulant fever (Mediterranean fever). In Great Britain this risk is small and, save in very exceptional circumstances, may be neglected.

The period of gestation in the goat is said to be about five months (150 days), and the average period in milk about nine months. In this country the daily yield may be expected to be about three pints; five pints is considered a high yield. The small yield of British goats is attributed to degeneration of the stock due to excessive in-breeding. The Board of Agriculture will not grant quarantine licences for the importation of stock goats for breeding purposes, owing to the risk of the importation of goats infected with undulant fever. The danger undoubtedly exists, but it seems not unreasonable to ask that a few picked animals should be admitted under special licences given after full inquiry. Certain breeds of foreign goats yield not only a large daily quantity of milk for a longer period, but, what is almost equally important, breed at more than one season, so that the owner of even a small herd may reckon with certainty upon a continuous supply of milk throughout the year.

From what has gone before it appears that theoretically the keeping of goats might be expected to do something towards the solution of the milk question, especially in suburbs or the outskirts of small towns, and especially in country districts, where it is often particularly acute. The great merits of the goat from the medical point of view are, first, that it is very rarely affected by tuberculosis, and secondly, that if the animal is kept by the consumer himself the necessity for manipulating the milk in various ways, for storing it, and sending it long distances by train, as happens commonly with cow's milk, is obviated. On the other side is the liability of the goat to undulant fever, which in this country is not at present, at least, a serious risk, and the uncertainty of the yield and of maintaining a steady supply, unless several goats are kept.

If goat keeping is to do anything of importance towards solving the milk difficulty it is clear that a good deal of organization will be necessary. It does not seem that it would be prudent to expect a goat to be in profitable milking for more than one year out of eighteen months, or perhaps fifteen months out of two years, remembering the period of gestation and allowing a reasonable interval after the animal dries off. For a regular supply, therefore, two or more she-goats must be kept and a he-goat must be available. These considerations seem to lead to the conclusion that a system of co-operation in areas is essential if the goat movement is to be put on a practical basis and to have the important and far-reaching results, especially in regard to the health of infants and children, which its enthusiastic promoters believe it capable of achieving.

ACCORDING to the twenty-second annual report of the Craig Colony for Epileptics, New York, there are colonies for epileptics in thirteen States of the American Union. It is estimated that there are 200,000 epileptics in the States, and that only 3½ per cent. are properly cared for. Of 1,320 deaths in the Craig Colony, 513 were due to causes related to epilepsy. In 600 autopsies gross brain lesions were found in about 60 per cent., but in only a few was there any condition that could have been treated surgically.

BRITISH PRISONERS IN GERMANY.

Two White Papers relating to the treatment of British prisoners of war and interned civilians in Germany have recently been issued. One contains correspondence between the Foreign Office and the United States Ambassador in Berlin, which is a record of the action taken by Mr. Gerard at the request of Sir Edward Grey, from October 13th, 1915, to April 6th, 1916. The camps reported on by Mr. Jackson and other representatives of the Ambassador are Stendal, Schneidemühl, Wülzburg, Halle; Wittenberg, Castle Celle, Spreenhagen, Munich, Ingolstadt, Burg, Blankenburg, Quedlinburg, Dyrzetz, Merseburg, Königsmoor, Hakenmoor, Fürstenberg, Orefeld, Friedberg, Mainz, Cassel and Langensalza, Soltau, Gütersloh, Güstrow, Döberitz, Neisse, Gnadenfrei, Wildemann, Clausthal, Bischofswerda, Spandau, Hannover, Münden, Göttingen, Tegel, Limburg, Giessen, Darmstadt, Mannheim, Heidelberg, Cologne, Germersheim, Villingen, Stuttgart, Weilburg, Magdeburg, Bayreuth, Kronach, Nürnberg, Würzburg, Hammelburg, and Landau. It is outside our province, even were space available, to summarize the reports; we can only touch on the points which have a directly medical interest.

Mr. Lithgow Osborne states that on October 29th, 1915, he visited the camp at Wittenberg. Among the British prisoners it was generally admitted that the food was sufficient in quantity and that it had recently greatly improved in quality. He had tasted it in the kitchen, and what he heard from the men confirmed him in his opinion that, apart from the sameness, the rations provided conformed to the standard necessary for good health. There were no complaints as to sanitation, and Captains Priestley and Vidal stated that the general health of the camp had been excellent since the disappearance of the typhus. There were many complaints as to the treatment of the prisoners in the matter of clothing, the delivery of parcels, and other matters; these the commandant, who seemed to have an unfriendly feeling to the English, was indisposed to consider. Mr. Osborne says that at Wittenberg those in authority, instead of regarding their charges as honourable prisoners of war, looked upon them as criminals whom only a régime of fear would suffice to keep in obedience. "All evidence of kindly and humane feeling between the authorities and the prisoners was lacking." On November 8th, 1915, Mr. Gerard himself visited the camp, and the impression which he derived from a careful examination of the camp and from long conversations with the prisoners was even more unfavourable than he had been led to expect. On November 22nd an inspection was made, on the order of the United States Ambassador, by Dr. Karl Ohnesorg, surgeon U.S. Navy; he reports favourably on the lazaret, but says that "unfortunately much had taken place in the camp which was not in accordance with recognized rules for the treatment of prisoners of war." He adds that this, happily, was changed, and the two medical officers, as well as the soldiers with whom he talked, said that then they had no complaints to make. The camp was again visited by Dr. Ohnesorg and Mr. E. L. Dresel on March 10th, 1916; they noted a decided improvement since the previous reports. A new commandant, General von Studtitz, had been appointed and had made a number of changes for the better. The clothing was entirely satisfactory and the canteen arrangements seemed to be sufficient.

At Stendal there were complaints that the prisoners were ill supplied with clothing, and that the food was very unsatisfactory. The camp was visited by Mr. Osborne on November 4th, 1915; he reported that while the men said the food was "not what they were used to," and that they lived largely on the contents of parcels sent from home, they admitted that, if necessary, they could live on the camp rations and still keep in good health. Mr. Osborne again visited the camp with Mr. Dresel on March 2nd, 1916, and reported further improvements. These reports, however, should be compared with Dr. Ribadeau-Dumas's account of Stendal, a summary of which appeared in the BRITISH MEDICAL JOURNAL of June 3rd (p. 801).

The reports on the other camps are on the whole favourable. The chief complaint as to food was that it was monotonous and unpalatable. At Döberitz Mr. Jackson was told by some Englishmen who worked in the kitchen

that their countrymen lived entirely on what was sent from home. The sanitation of these camps is described as good, and the physical condition of the men as excellent. It is satisfactory to record that some prisoners bore testimony to kind treatment received from German medical officers. As far as it goes, the correspondence shows that there has been a considerable improvement in the German prison camps since last year. But in view of the statements made by men who have been repatriated and of accounts by Frenchmen and others of the way in which they have been treated, the evidence of the American inspectors, most praiseworthy as the efforts of Mr. Gerard and his colleagues have been, cannot be accepted altogether without reserve.

The Food Question at Ruhleben.

The other White Paper contains a report by Dr. A. E. Taylor on the conditions of diet and nutrition at the internment camp at Ruhleben; it is addressed to the United States Ambassador, and forwarded by Mr. Gerard to Sir Edward Grey. Writing on May 1st, 1916, Dr. Taylor states that he visited that camp during ten days, spending a number of hours there every day. He studied the diet for one week, qualitatively and quantitatively, witnessing the weighing of the food, and eating the midday meal himself. From the standpoint of their relation to the diet the men confined in Ruhleben may be divided into five groups: (a) The so-called pro-German group—men technically British subjects who have lived so long in Germany that they have become habituated to German tastes and sentiments. These men receive limited food supplies from German sources outside the camp. (b) A Jewish group which receives no supply from outside the camp. (c) A group which, for one reason or another, receives no supply from outside the camp; this group probably includes several hundred. (d) A group—far the largest—which receives a number of packages from relief societies, trades unions, etc., in Great Britain. (e) Men who receive supplies from their own families and friends in Great Britain. There is a relief fund in the camp available for those who choose to apply—the relief being regarded as a loan to be repaid at some future time. There are men who voluntarily subsist upon camp rations alone, and will not be beholden to, or ask for, aid.

The diet of the camp is fashioned after the monthly "Speiseplan" supplied by the authorities, and based upon the dietetic standards of Professor Backhaus. It provides for 80 to 85 grams of protein, containing the necessary amino-acids—30 grams of fat and 500 grams of carbohydrates—corresponding to about 2,700 calories.

The diet is arranged to include the minimal amount of fat, a sufficiency of protein, the necessary salts, vitamins, and enough raw or fresh-cooked food to maintain the health of a non-working man. Dr. Taylor observes that the men who took the camp ration actually got 99 grams protein, 25 grams fat, 525 grams carbohydrate, corresponding to 2,740 calories.

"It is clear that for the men who took the ration it was quantitatively adequate, except for the difference in fat, even if the men who took the ration had subsisted entirely upon it," and two-thirds of them did not.

If the whole 3,700 in the camp had lined up for the ration it would not have gone round, but Dr. Taylor is convinced that the food sent in from outside was equal to one-half to two-thirds of that supplied by the camp authorities. The men engaged in the kitchens had to prevent waste and estimate as near as they could the amount of camp rations which would be called for. On two days the supply of fresh fish gave out with 100, and with 250 men still in line. These were provided with tinned herrings. Five out of seventeen of these tins which Dr. Taylor saw opened were putrid, and many of the men naturally refused this food. Dr. Taylor writes:

I was not able to observe that the nutrition of the men who subsisted largely or entirely upon the camp ration was any lower than that of the men who subsisted partly or entirely upon supplies sent from abroad.

With one exception (the tinned herring), the different food-stuffs have been found to be of satisfactory quality. . . .

The cheese and cocoa were not of high grade, but were unspoiled. The margarine was not a high-grade product, but was sweet. Fresh fish was served during three days of this survey, and was of excellent quality. The potatoes were of good grade. The bread corresponded in quality, texture, and

appearance with the black bread served in the ordinary beer restaurant in Berlin. The Englishman dislikes this bread and, practically speaking, eats none of it.

The evidence of Dr. Taylor, then, is conclusive as to the physiological adequacy of the ration given out to those who chose to take it.

The British object to the German cooking as displayed under the exigencies of camp life. On this head Dr. Taylor makes the following statement:

It is clear, from conversations with even the most violently protesting prisoners, that their objections do not apply materially to the foodstuffs, and do not mean to imply that the food as cooked is unfitted for human consumption. They simply mean that it is so different from the food to which they are accustomed that they cannot learn to regard it with anything else than distaste.

Replies to widespread questioning of men in normal flesh indicated that loss of weight had not been frequently observed; indeed, some men had gained in weight. On the other hand, many prisoners who were obese had lost weight, and the diet is obviously not calculated to produce obesity.

The supplies received from abroad consist of 800 kg. [1,760 lb.] of bread daily, and varying amounts of butter or margarine, tinned British army ration, corned beef, sugar, cakes, biscuits, tea, jam, honey, bacon, and various titbits.

The camp ration is particularly deficient in fat, and inquiry has led Dr. Taylor to the conclusion that the supplies from abroad of cakes, sweets, and tit-bits are disproportionately large, and of fats surprisingly small. Some men receive far more than they can consume, others a moderate supply, several hundred none or next to none. Some are generous, but many do not believe it proper to receive food from their fellow prisoners.

It is clear that there is in Great Britain a complete, and from the standpoint of the prisoners in Ruhleben most lamentable, lack of organization in the selection of foodstuffs and distribution of food packages for these prisoners. It is again the old story of unorganized charity being qualitatively inefficient and quantitatively wasteful.

Dr. Taylor points out that, from a nutritional point of view, the two sources of food supply, from Germany and from Great Britain, should complement each other so as to secure a satisfactory ration. The sending of supplies from Great Britain should be organized and controlled, and the German authorities should cease to attempt to furnish a balanced ration with the money it was decided to apply for the purpose, devoting their outlay entirely to certain articles of food. The following general arrangement in diet is proposed—the figures have been prepared for 3,500 men:

Suggested outlay from the German side per man per day: Three days a week, 125 grams fresh meat; two days a week, 200 grams fresh fish; one day a week, 150 grams tinned corned beef; one day a week, 150 grams smoked fish. Each day in the week 1 kilo potatoes and 300 grams of a root or leaf vegetable.

Suggested outlay from the British side per man per day: Each day in the week, 400 grams white bread, 30 grams butter or margarine, 50 grams bacon, 50 grams sugar, 30 grams jam or preserves, 30 grams Quaker oats, and 30 grams condensed milk; tea and coffee as needed.

Such a diet, says Dr. Taylor, would contain 80 to 90 grams of protein, about 65 grams of fat, and 425 grams of carbohydrate, and would yield about 2,600 calories. It would contain the desirable amount of fat, it would conform to the tastes of the prisoners, and it would provide the interned men with certain desired articles which the German authorities do not supply.

In acknowledging the report Sir Edward Grey "fears that the circumstances will not permit of the adoption in practice of the recommendations made by Dr. Taylor in regard to the establishment of an organization controlling the supply of food parcels sent to the camp from this country." He promises, however, to communicate the report to the Prisoners of War Help Committee with the request that it be made known as widely as possible among the various societies and individuals by whom such parcels are now being sent to Ruhleben.

It is certainly a task which such societies should take up, for it will be a disgrace to this country if the defects in organization pointed out by Dr. Taylor are not remedied.

A PAMPHLET entitled, *An Every Day Directory for War Time*, has been compiled and published (price 6d., post free 9d.) by the Women's Imperial Health Association, 7, Hanover Square, and the Women's Emergency Corps, 15, York Place, Baker Street, W. It includes women's work, but does not exclude other organizations.

British Medical Journal.

SATURDAY, JUNE 17TH, 1916.

RECIPROCAL DUTIES OF STATE AND PROFESSION.

THE General Medical Council at its recent session passed two resolutions which will undoubtedly prove to be of serious importance to the medical profession. The two have a certain relation to each other, for both are concerned with the relation of members of the medical profession to the State.

The first resolution¹ seemed to follow naturally on a series of disciplinary cases in which medical practitioners were charged with covering midwifery practice by uncertified women. The President was asked to draw up a warning notice in consultation with the legal advisers of the Council. It will not be difficult to draw up such a warning notice if it is to be only a general threat of penalties for the covering of uncertified women, but if it is to contain any instruction as to the limitations of what is meant by "covering," it will have to be most carefully framed to avoid injustice, not only to practitioners, but to the public. With the Midwives Act as it stands, the dividing line between "covering" which deserves punishment, and a proper and sympathetic service to the poorer classes of parturient women is not always easy to draw, and unless the term "covering" is very strictly defined, there will be great danger that fear of transgressing may impel many practitioners to refuse to go to any case of confinement which is being attended by an uncertified woman. The ideal put forward by Dr. Newsholme, that there should be a proper supply of certified midwives in every area, and that county councils or town councils should co-operate with the State, each paying half the fee of a certified midwife when the mother cannot afford it, is a long way from being realized either in country or town areas generally; a large percentage of mothers are still unfortunately being attended by handy women, either on the ground of expense or because there is no certified midwife in the district. If in one or other of these circumstances a doctor is called in because some difficulty occurs, what is his duty? It would not be in the public interest to make a rule which would deter doctors from attending in such cases. That is not the way to bring pressure to bear on public authorities in town or country. For a doctor habitually to "follow" (to use the popular term) an uncertified woman whom he knows to attend confinements "habitually and for gain," would, as a rule, rightly come under the term "covering," and it is a matter for regret that there should be thought to be any need for a warning notice to this effect; but will a doctor be running any risk of disciplinary measures if without any previous arrangement he responds to the call of such a woman, or will he be expected to act as a public detective and report such cases to the authorities at the risk of a charge of "covering" if he failed to report them? It is no use burking the fact that, rather than run such risk or incur the odium of reporting a patient for employing an uncertified woman (for that is certainly how the patients will regard any such

detective work), many doctors will prefer to be otherwise engaged and unable to attend any case for which they have not been previously engaged or to which they do not receive a call for aid on the official form from a certified midwife. The mere mention of this, among many other difficulties that arise every day in general practice in connexion with similar cases, makes it imperative that any warning notice should be not merely one more of those threats of pains and penalties with which the profession is so freely bombarded to-day, but that it should be educative and fully explanatory; while protecting the mothers as well as the midwives so far as possible from unqualified women, it should not place medical practitioners in a position of doubt and difficulty. The fairness and efficacy of any warning notice on the subject will depend entirely on the way in which it is drawn up and the information it gives, and we repeat that the task committed to the President and legal advisers of the Council is by no means easy, and we feel sure that the result will be very carefully scrutinized by the Council when the draft comes before it.

The second resolution of the General Medical Council² to which we refer is in the nature of a recommendation that "instruction should be given, in the courses of forensic medicine and public health, or otherwise, on the duties which devolve upon practitioners in their relationship to the State and upon the generally recognized rules of medical ethics." To carry out part of this resolution ought to offer no insuperable difficulty to the colleges and medical schools. Some instruction is already given, though perhaps not so fully as it ought to be. Instruction in the duties of practitioners in regard to coroners' cases and the giving of evidence in either civil or criminal courts ought undoubtedly to receive more attention than is generally given to it. The duties of the prompt notification of infectious diseases, including tuberculosis; the duty, so far as it falls on medical practitioners, of notifying births; the law as to death certificates, certificates in lunacy, and so on, afford material for lectures to students which is not difficult to handle. When we come to what may be called more specialized obligations, difficulties will arise which will compel lecturers to confine themselves within narrow limits. For example, the duties of medical officers of health, Poor Law medical officers and public vaccinators, school medical officers, and many other public medical officials, could not be treated in anything but a very summary way in a general course.

But the hard experience of the profession in recent years compels the suggestion that the rights of practitioners as well as their duties are subjects on which students should be instructed. The resolution speaks only of the duties of practitioners, but the systematic and often crude attempts of many public officials, especially of too many coroners, to require, with a show of authority and without a fee, services which practitioners are in no way legally bound to render, make it important that if legal duties are to be explained, legal rights ought equally to be described.

Again, the working of the Insurance Acts offers a wide field for instruction, since the duties and rights of practitioners in relation to the State in this respect are often matters of great importance; yet it is more than doubtful whether any course of lectures to students could satisfactorily cover even a fraction of this field. In the first place, ordinary university professors probably know nothing of these matters

¹ SUPPLEMENT, June 1st, p. 128.

² SUPPLEMENT, this week, p. 145.

worth lecturing about beyond the vaguest generalities, and the complexion placed on these would depend far too much on the personal feelings of the lecturers in favour of or against panel practice.

The second part of the resolution—that referring to instruction in medical ethics—will also present difficulty in application. A distinction must, of course, be drawn between the “ethical rules” of the British Medical Association and “generally recognized rules of medical ethics.” The “ethical rules” are, of course, really rules of procedure in determining cases where ethical conduct is involved, and in most cases the question is one of obedience to or neglect of decisions of the Representative Meeting or the local Division. For example, the numerous decisions of the British Medical Association adopted by Divisions with regard to minimum salaries or fees that should be accepted are regarded as of such importance that in not a few cases non-compliance has led to expulsion from the Association on the ground of conduct “detrimental to the honour and the interests of the profession.” Loyal members of the Association have often longed for some means of enforcing its rules of conduct on the attention of medical students, but can it be claimed that the decisions of the Association on such matters come within the range of instruction contemplated by the General Medical Council? On the other hand, if this cannot be claimed, what is left to the lecturer on medical ethics? The British Medical Association has from time to time covered by its pronouncements practically the whole field of medical ethics, but who is now to determine which of its pronouncements are “generally recognized”? Is this to be left to each university lecturer, or does the General Medical Council now intend to proceed to draw up a sort of code of honour binding on all medical men, failure to comply with which may involve removal from the *Register*, or some lesser penalty which the Council may obtain power to inflict? Something of the sort might be of great advantage to the profession, and the task of the General Medical Council would be greatly lightened by the accumulated experience and help of the British Medical Association, but in the meantime lectures to students on the generally recognized rules of medical ethics can cover little ground. Such things as undercutting one's neighbours, ingratiating oneself with patients first seen in consultation with a colleague with a view to attract them from him, the innumerable ways of touting for patients short of open advertising, and other matters of the kind, could of course be referred to in lectures to students, but all such references could only be in the most general terms.

ENROLMENT A DUTY FOR MEN BETWEEN 41 AND 45.

THE memorandum issued by the War Office to all medical men who may be under the age of 45, and the covering letter from Sir Alfred Keogh, which we publish in this week's SUPPLEMENT, p. 141, will bring home once more to the minds of all medical men the importance of proper organization of our profession in the national crisis.

We dealt last week with the position of medical men under 41, who now come under the provisions of the Military Service Acts; and we pointed out how essential it is to their own interests, no less than to the interest of the country, that every one of them should be enrolled before June 24th. This week it is our duty to call attention to the later part of Sir

Alfred Keogh's letter, wherein the Director-General appeals to men between the ages of 41 and 45.

The provisions of the Military Service Acts limit compulsion to those single men who had not reached their 41st birthday on March 2nd last, and to those married men whose 41st birthday is later than June 24th. But the difficulty of supplying the medical needs of the navy and army from men below this age, with due consideration to the maintenance of proper and sufficient treatment for the civilian community, led long ago to the raising of the age up to which medical men are eligible for service at home or abroad. Any medical man whose age does not exceed 45 next birthday, and who is physically fit and acceptable to the military authorities, may apply for a commission in the R.A.M.C. Not all the medical men under 45 are wanted for the army, nor could all be spared without serious dislocation of the medical requirements of the civilian population. How, then, can selection be made? So long as compulsion is not applied to men between the ages of 41 and 45, there are only two methods by which voluntary assistance can be obtained from them: First, the military needs may be made known by advertising them, when such men as are moved by the spirit of patriotism may offer their services. The objections to this method are that no individual can possibly know in what direction his services are most needed. In his desire to serve his country by taking a commission he may be putting the area in which he practises to serious inconvenience. Moreover, at what he believes to be the call of duty, he may be inflicting great hardship upon himself and his dependants—hardship which might have been avoided by a process of judicious selection by some one in a position to know all the requirements and difficulties of the case. The second method is to introduce an intermediate body possessing knowledge both of the military requirements and of the civilian and individual difficulties. Such bodies are the Central Medical War Committee and the Scottish Medical Service Emergency Committee. These Committees are able to view the situation in its proper proportions owing, on the one hand, to their close relations with the medical military authorities, and on the other hand to their sympathetic understanding of the position of the medical profession and of the civilian community.

The scheme of enrolment is accepted by Sir Alfred Keogh as by far the best and fairest method for obtaining medical officers for the army. In his letter the Director-General says: “Practitioners between 41 and 45 years of age are in fact in a position, by now enrolling, to assist in a peculiarly important degree the achievement of the objects of this scheme for the organization of the profession, thus enabling the Government both to meet the pressing needs of the forces at home and abroad, and to ensure the maintenance of an adequate medical service for the civil population.”

The scheme completely loses the spirit of fairness unless the majority of men agree to accept it and the obligations it involves. It is inconceivable that any medical man exists in this country who does not wish to serve at the present time wherever he is most needed. It is certain that every man is anxious to make whatever sacrifices are demanded of him. Is it possible that any man will continue to hang back, will refuse to take his part in a scheme of organization approved by the Government, supported by the strong appeal of the Director-General, designed and carried out by committees which have the assistance of the heads of the profession; a scheme which satisfies the instincts of patriotism and equity?

He must be a bold man who sets his private judgement against a proposition supported by such weight of opinion as is found to support the scheme of enrolment.

We trust, therefore, that the appeal of Sir Alfred Keogh to the medical profession may meet with immediate response, and that within a very short space of time there will not be a man left who is under 45 years of age who will not be enrolled with one of the committees responsible for organizing the medical services of the country in time of war.

COMMISSIONS FOR MEN BETWEEN 45 AND 55.

WE are authorized to state that the War Office has decided to give commissions in the R.A.M.C. to medical men between 45 and 55 willing to undertake whole-time general service in the United Kingdom. The announcement will, we believe, be received with satisfaction by a considerable number of medical men between the ages mentioned, who are anxious to serve the country, but have hitherto been debarred from doing so on the score of age. This step has been taken owing to the growing demands upon the Army Medical Service—demands which, we believe, are particularly urgent at the present time. Every man who thus offers himself for whole-time general service in the United Kingdom will set free one younger medical officer now employed in this country to serve with the armies which the country has in France, in the Mediterranean, in Mesopotamia, in India, and in Africa.

Information supplied to the Central Medical War Committee at its meeting on June 14th makes two points clear. The first is that there is an urgent necessity for more medical men to meet the demands of the new units of the new armies, and to make good the wastage which must continually go on in all the many and various fields in which the British armies are operating. The second point is that the War Office seems to be doing all that is possible to meet the demand by calling on all young men who pass qualifying examinations to join the R.A.M.C. at once, and by making an appeal to young graduates in the Overseas Dominions. All these are eligible to receive commissions in the R.A.M.C. for general service abroad. The War Office is considering how far it may be possible to employ senior medical students as residents in hospitals, and other methods of dealing with hospital work are being developed.

A medical man who has not previously engaged in any form of military service must undergo a period of training in his special duties in this country; this period has been reduced to the lowest possible limit. There are, however, as has been said, a considerable number of medical officers in the Territorial Force who had undergone training before the war and have since gained much practical experience. It is such men that the War Office would prefer to send abroad in considerable numbers, and it is the places of such men with the forces at home that can be filled by men between the ages of 45 and 55. We understand that a certain number of medical men between these ages have volunteered to serve abroad and are being employed in the Mediterranean.

The decision of the War Office affords a great opportunity to medical men between 45 and 55 who can see their way to get free from their present civil obligations and accept commissions in the R.A.M.C. with the home armies. It must, however, be understood that the offer applies only to men who will

undertake to give whole-time service and to go to any place in the United Kingdom to which they may be sent.

RECOGNITION OF PROFESSIONAL COMMITTEES UNDER THE MILITARY SERVICE ACT.

THE Central Medical War Committee for England and Wales and the Scottish Medical Service Emergency Committee have been recognized by the Army Council as the Central Professional Committees for England and Wales and Scotland respectively, under the regulations made by the Order in Council in compliance with the provisions of the Military Service Act, 1916 (Session 2). The Reference Committee appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England has also been approved by the Army Council under paragraph 5 (1) of the regulations.¹ Communications from practitioners in England and Wales should be addressed to the Secretary, Central Medical War Committee, 429, Strand, London, W.C., and from practitioners in Scotland to the Secretary of the Scottish Medical Service Emergency Committee, Royal College of Physicians of Edinburgh. The Secretary of the Committee of Reference is Mr. F. G. Hallett, the Conjoint Board in England, Queen Square, Bloomsbury, W.C.

THE BATTLE OF THE CLUBS IN NEW ZEALAND.

WE desire to call attention to a notice which appears on page 38 of the advertisement columns with reference to friendly society lodge appointments at Wellington, New Zealand. For some time the relations between the lodge doctors and the friendly societies throughout Australasia have been very unsatisfactory, and though in New South Wales the doctors have been able to some extent to better their position, in New Zealand they have met with little success. At present Wellington is the centre of dispute, and the New Zealand Branch of the British Medical Association appeals for the loyal co-operation of all doctors in the mother country. Briefly the facts seem to be as follows: For some years past the lodge doctors have received 15s. per member a year; for this they had to give medical and surgical attendance to the member, his wife, all male children up to 16 years of age and female children to 18 years, as well as the widowed mothers of single members. Operations, confinements, and anaesthetics were not included, and there was a distance limit of three miles. At the conference at Auckland in 1914 it was decided to give notice to the lodges to bring into force a new standard agreement at the beginning of 1915, but the outbreak of the war prevented this being carried out. As a large number of doctors joined the forces, not only did the work of those remaining increase, but, with greatly increased expenses, the position became practically unbearable, and the lodge doctors, after notifying the Wellington Division of the British Medical Association, approached the lodges for better terms. The sum of 24s. a year was demanded, and the doctors handed in their resignations to take effect at the end of 1915, the requisite notice being given in each case. A minority of the lodges adopted the new terms at once, except that the doctors agreed to accept 21s. provisionally until the end of the war. The majority of the lodges, however, refused to agree to any increase over the 15s., and they immediately issued circulars seeking applicants on the lodge terms for the appointments. The Wellington Division then took the matter up vigorously, and the resignations of the doctors took effect, the lodge members only being treated as private patients; for this the lodges had to pay. In this predicament the lodges approached the Minister of Public Health (the Hon. G. W. Russell), who, after hearing the friendly societies, asked for a deputation of medical men. Accordingly, on April 11th, members of the Wellington Branch formed a deputation

to the Minister and presented a memorandum on behalf of the lodge doctors. It was made clear that, though the doctors would be willing to treat the families of lodge members absent at the war at the old rate of 15s., the full rate required for members and families would be 24s., a reduced rate of 21s. being accepted in some cases until the end of the war only. Statistics obtained by the Wellington Division showed that on an average each family consisted of four persons, and the memorandum pointed out that in Great Britain under the Insurance Act each individual insured person paid 7s. for himself alone, as compared with the 15s. paid for four persons in New Zealand. The Minister of Public Health thought that a rise from 15s. to 24s. was large, and that the present was not the time to ask for increases. The deputation pointed out that though there was a rise in the cost of living, unemployment was never less in evidence, and the working man was better off now than ever. The 15s. rate worked out at only 10½d. per attendance on the average, and in some cases as low as 3d. to 5d. The Minister asked that he should be allowed to call a conference of the lodges and the doctors; he was prepared to admit that 15s. was too low, but he was also prepared to admit that 24s. was too high. His position placed on him the necessity to find medical service for every part of the country, and if a large body of persons were unable to get medical attendance at a price they could afford, he would have to find some method to supply the need. The suggested conference has since been held, but no agreement was arrived at. Some of the lodges appear to have boasted that they would be able to get any number of medical men from Great Britain or America to accept their terms, and the New Zealand Branch now confidently appeals to all medical practitioners to assist in its fight for reasonable terms. The societies are evidently ready to take advantage of the ignorance as to the real state of affairs of doctors in the mother country who might think to better themselves by going to New Zealand, but there can be no excuse for any such ignorance, and the real position will be fully explained to any doctor who desires full information, if he will apply to Dr. H. G. Gibbs, Honorary Secretary New Zealand Branch, 123, Willis Street, Wellington, New Zealand, or to the Medical Secretary, British Medical Association, 429, Strand, London.

FEVER WITH MENINGISMUS.

In the *Muenchener medizinische Wochenschrift* for May 9th, 1916, Dr. Richard Stephan, of Leipzig, describes an outbreak of febrile illness associated with meningismus which occurred during the summer and autumn of 1915. The first cases were observed during May. The illness was ushered in by rigor with pyrexia, headache, and marked hypersensitiveness to either active or passive movements. The mucous membrane of the tonsils and pharynx was red and swollen, and from the third to the sixth day catarrhal bronchitis frequently supervened. Stiffness of the neck muscles and bradycardia were also observed. Diarrhoea occurred in some cases, and acute dilatation of the heart was also met with. Some of the cases exhibited herpes labialis. A point of particular interest is that several developed haemorrhagic nephritis. In spite of the gravity of some of these symptoms the prognosis proved to be good. On lumbar puncture the cerebro-spinal fluid was found to be clear and showed no increase in its albumin content. The centrifugalized deposit yielded few cells of any kind, those present consisting of lymphocytes and polymorphonuclear leucocytes. Gram-negative cocci were seen in the latter. This clear cerebro-spinal fluid on incubation yielded in every case after enrichment of the fluid by Kutscher's method, and in half of the cases without such enrichment, a Gram-negative diplococcus which was distinguished from the meningococcus by its profuse growth on agar, and also by agglutination tests; but this matter is to be more fully dealt

with by Drs. A. Harzer and C. Lange in a future communication. From the nasopharyngeal secretion of the cases the meningococcus could not be isolated. Blood cultures gave a negative result. In two of the cases that developed haemorrhagic nephritis Gram-negative diplococci were observed in the centrifugalized deposit of the urine. Investigation as to the occurrence of the diplococcus isolated from these cases in the upper respiratory passages of normal persons, and of persons suffering from other diseases, has had to be deferred until its serological characters have been defined more fully. As regards treatment, Stephan states that good results followed the administration of hexamine (urotropin), which was given without harm to cases after the development of haemorrhagic nephritis. The dose was 0.5 gram of hexamine six times a day. As has been mentioned, prognosis was good, recovery taking place as a rule in eight to ten days. No mention is made of any case having died. The malady may be described as an acute febrile illness with meningismus. Stephan regards the condition as due primarily to a bacteraemia, the upper respiratory tract or the lung being the portal of entry. As to whether this acute meningismus is a new disease, hitherto unknown, or not, Stephan is uncertain; but he believes that in all probability a great number of cases of so called febris ephemera, febris herpetica, or febris cryptogenica belong to this group. In any case he is convinced that the disease is distinct from cerebro-spinal fever. In view of the study which is being made in this country at the present time of Gram-negative cocci in connexion with outbreaks of cerebro-spinal fever, no little interest attaches to Stephan's communication.

WEIL'S DISEASE.

In 1886 Weil described a type of epidemic jaundice that has since gone by his name; its etiology has till quite recently been obscure. A similar, if not identical, disease appears to exist in Japan, and here it is caused by infection with a particular spirochaete, as was described in the *BRITISH MEDICAL JOURNAL* of April 1st on page 491. Advices from Germany report¹ that in that country also a spirochaete has been isolated from the blood of patients with acute infectious jaundice by Hübener and Reuter, and by Uhlenhuth and Fromme. This organism can be cultivated from the circulating blood only during the first few days of the fever; in a case reported by G. Herxheimer² ending with a fatal result due to the occurrence of bronchopneumonia, the spirochaetes could be demonstrated in the patient's tissues by Levaditi's method of staining with silver. The liver and kidney were the organs mainly involved, and the latter was found to contain many more of the spirochaetes than the former. The spleen, curiously enough, showed no enlargement, and was practically normal. Herxheimer points out that several recent writers besides himself have failed to confirm Weil's original statement that the spleen is enlarged in this form of epidemic jaundice. Two cases of the disease are reported by Krumbein and Frieling;³ here the source of the infection was a dog acutely ill with jaundice that lasted about four weeks. The infection in one case may have taken place by means of a scratch on the hand inflicted by one of the dog's teeth in the process of washing out the animal's mouth with hydrogen peroxide on the second day of its illness. Both patients—the dog's owner and a medical man—were daily in close contact with the animal, and may have become infected by flea-bites; both had attacks of acute febrile jaundice, and both recovered. The incubation period of the disease could not be determined with any certainty in these two instances, but Krumbein and Frieling argue that it was probably nineteen days in the case of the owner whose hand was scratched, and twenty-two days in the other case.

MEDICINE IN THE ENCYCLOPAEDIA OF RELIGION AND ETHICS.

It is with a mixture of wonderment and respectful admiration that the eighth volume of Dr. Hastings's great *Encyclopaedia of Religion and Ethics*¹ must be welcomed in these days when nearly the whole world is at war, and when publishers and editors in particular are hard put to it to go on. Still this volume is only a little behindhand, for although its title page bears 1915 the volume itself has just been issued. It contains 910 pages of double columns and not less than 1,200 words on each; its writers, of many nations and races (including German professors), number 185; and its articles more than 260—it is an achievement. The first article, on "Life and death," by Professor J. A. Thomson of Aberdeen, deals, of course, with many medical matters; and those which follow it, and which look at the subject from Primitive, American, Babylonian, Buddhist, Celtic, Chinese, Christian, Egyptian, and many other standpoints, contain not a little which is of intense interest to the thoughtful physicians who "beside the unveiled mysteries of life and death go stand." Another group of articles, occupying about fifty pages, discusses marriage in all its relations, including the medical, and among all races. It is a storehouse of most interesting information such as could not easily be gathered from any other single source. Milk (bathing in it as well as drinking it) is another article of interest for the curious. Madura is described, and its wondrous shrine, but not (indeed, one could hardly expect it) its "foot"; lycanthropy is entertainingly explicated; the Melanesians and Malaysians have all their inmost secrets laid bare; melancholy is intimately inquired into, its medical aspects set forth, and dear old Robert Burton, "by profession a divine, by inclination a physician," is referred to; magic is brought very near to ancient medicine; mana, which seems to be, like taboo, a word which can mean almost anything and nearly everything, gets full consideration; and therapeutic effects of the wonderful Midsummer-day fires of Morocco are not forgotten. Monsters are investigated from a biological standpoint by Dr. W. L. H. Duckworth of Cambridge, and from an ethnic one by J. A. MacCulloch (who also writes on metamorphosis, miracles, and mouth), but the ethics of what is to be done with them in relation to social status, marriage, legal position, and the like is prominent by its absence; indeed, the page and three-quarters given to this subject is meagre in the extreme. Another criticism arises in connexion with the articles on missions, which occupy fifty-one pages, but through which one has to search with microscopic minuteness in order to discover (on p. 740) a reference to medical missions. These, however, are trifling faults to find in the midst of so much which is magnificent, massive, and mature.

RURAL SANITATION.

A CORRESPONDENT suggests that it would serve the turn of local authorities to send their medical officers of health for a tour of instruction in the parts of France at present guarded by the British armies. If the chairmen of the public health committees were to go also it might be still better. Starting from conditions worse than we are accustomed to put up with in this country, the Army Medical Service has brought about a state of things in the small towns and villages within the British military zone a great deal better than anything known in similar places at home. The transformation is due partly to zeal and knowledge, partly to the possession of authority and the command of adequate labour, and partly to liberal expenditure. It is the old story of the trained practical expert in command possessed of adequate means and unhampered by amateurs who may be excellent tinkers, tailors, or cabinet-makers,

but are wholly ignorant of sanitary administration or the scientific principles on which it rests. Lieutenant-Colonel Herbert Jones, who has had a long experience of public health administration in civil life, said at the conference at the Royal Sanitary Institute last week that he had been astonished at the rapidity with which sanitary improvements could be carried out in the army at home. To see the work on a large scale it would, we believe, be necessary to visit France.

NAPOLEON AND TISSOT.

DISCUSSIONS on the real and supposed diseases of Napoleon already make a considerable body of literature, and there is no sign that interest in the subject is dying out. The latest new document we have seen is published in *Paris Médical* of May 13th. It is a letter written to Tissot, the famous physician of Lausanne, and is to the following effect: "Sir,—Without having the honour of your acquaintance, having no other right than the esteem with which your writings have inspired me, I venture to importune you with a request for your advice on behalf of one of my uncles who suffers from gout. Humanity, Sir, bids me hope that you will deign to reply to this request for a consultation so ill expressed. I myself for a month past have been troubled by a tertian fever, which makes me doubt whether you will be able to read this scrawl. I conclude, Sir, with an expression of the perfect esteem with which the reading of your works has inspired me, and the sincere gratitude which I owe you. I am, Sir, with the most profound respect, etc." Tissot did not think the letter worth answering, and, indeed, as a statement of a case it is pitifully vague, and as a literary composition it is poor and feeble, very different from the lightning strokes of the Napoleonic pen. This may, perhaps, be explained by the illness of the writer. At any rate, Tissot endorsed the letter "Not interesting." He was no prophet, or the signature, "Buonaparte, artillery officer in the regiment of La Fère," would certainly have aroused his interest. Perhaps the poor lieutenant had forgotten to send a fee. Tissot wrote much and on the most various subjects—inoculation, bilious fever, the health of literary men, epilepsy, diseases of the nerves, and onanism; the last of these books made his name known throughout the world. Probably the works which gained for him the admiration of the future emperor were his popular treatises on health, which went through countless editions and were translated into most European languages, and his essay on the health of men and women of the world.

LOCALIZATION OF BULLETS.

A REPORT of a demonstration of a new *x-ray* apparatus by Hasselwander of Munich for the correct stereoscopic showing of bullets, etc., was published in *Electrical Engineering* for May 11th. In this method a land surveying instrument called the stereoplanigraph is used, and the idea appears to be to reproduce by means of this instrument and the stereoscopic image an automatic modelling in all three dimensions of space of the radiograph. It is claimed that this method is very exact; that it has been used in 100 cases with complete success; and that it gives a permanent record of each case. It seems to be a distinct advance in the methods of stereoscopic radiography, but it is not clear from the description that, from the practical point of view—namely, the exact localizing of a foreign body for the purposes of surgery—it equals in exactitude and ease of application the cross-thread method devised by Mackenzie Davidson.

THE King has appointed Mr. John B. Story, M.B., F.R.C.S.I., Professor of Ophthalmology and Aural Surgery in the Royal College of Surgeons of Ireland, to be Honorary Surgeon-Oculist to His Majesty in Ireland, in the room of the late Dr. Charles Edward Fitzgerald.

¹ *Encyclopaedia of Religion and Ethics*. Edited by James Hastings, with the assistance of John A. Selbie, M.A., D.D., and Louis H. Gray, M.A., Ph.D. Vol. viii. Life and Death—Mulla. Pp. xx, 910. Edinburgh: T. and T. Clark. 1915.

THE WAR.

ABDOMINAL INJURIES.

(From a Correspondent in Northern France.)

ALL along the British front cases of gunshot wound of the abdomen are the subject of special arrangements. These are not invariably identical and nowhere are they regarded as unalterable should the needs of the moment seem to dictate their modification. Everywhere, however, the same underlying principles prevail.

Whatever be the ordinary rules of the area for dealing with casualties, they are held to apply to no case which there is reason to regard as one of penetrating wound of the abdomen. Unless any such case obviously will not bear transportation, it is to be sent without delay to the nearest medical unit at which it can be detained and suitably treated for any desired length of time.

The official status of the unit to which the case is sent may vary, but it will always be one possessed of an operating-room kept ready for instant use; of a personnel which includes women nurses and at least one surgeon versed in abdominal surgery; and of a ward equipped on the lines of an ordinary hospital and so disposed that its current work and occupants need not be disturbed if occasion require that the rest of the establishment be evacuated or moved elsewhere at short notice.

Units which meet these desiderata are to be found all along the line. As a rule, they are casualty clearing stations, but occasionally they are or have been "tent sections" of field ambulances which have budded off the original unit and almost lost any connexion therewith. Their distance from the trenches varies, but is never so great that it could not easily be traversed by a motor ambulance within an hour and often in half that time.

It would be wrong, however, to conclude that not more than about sixty minutes will commonly elapse between the receipt of an abdominal wound by a soldier and his appearance as a patient in an operating theatre. There have been instances in which this has occurred, but as a rule it is not to be expected. The determining factors are numerous, and the precise distance between the spot at which a man is wounded and the unit at which he is to be treated is about the least influential of all of them. The difference that it can make is a matter merely of minutes, that caused by the rest may be one of hours.

Among the more important factors are the following: (a) The occupation of the patient at the time he is hit; (b) the hour of the day; (c) the state of the weather; (d) the extent and character of the fighting at the time in progress; (e) the character of the communications between the fire trenches and the regimental aid post and between the latter and the advanced dressing stations; (f) the extent to which the roads immediately behind the fighting line are exposed to artillery or rifle fire.

It is obvious that any of the first three of these factors may vary greatly from day to day, while in regard to the three latter it may be said that hardly two consecutive miles of trenches seem to present quite the same problem from the point of view of evacuation of casualties.

As for the effect of occupation, a man may be struck when (1) in a fighting or communication trench, or (2) when out in front of the trenches as a member of a wire-repairing or other working party; or (3) when engaged in an active attack on the enemy; or (4) while going up to or back from the trenches by an above-ground route.

In case (1) he is likely to receive immediate attention, though whether he will be removed to the rear forthwith is quite another question. In cases (2) and (3) it may sometimes be impossible to get him brought in for a very long time. In case (4) he might not be found for an indefinite period. There are plenty of places where the ground behind the lines is either woody or obscured by hedges and bushes.

As for the other factors it may be impossible to spare men to take an abdominal case to the rear if active fighting

is in progress, or heavy rain may render a communication trench temporarily impassable; or the enemy may take it into his head to pepper with shells a road along which the patient and his bearers will have to pass when they have left the trenches behind them, and such "strating" may be kept up for hours.

Other considerations are the following: Some lines of trenches, either because the ground is flat or the enemy occupies a slight elevation, can neither be entered nor left except under cover of darkness. Other trenches, either because the ground behind them lies low or is covered by trees, can be entered in daytime and by an above ground route without material risk unless the enemy happens to be shelling what is usually "dead ground."

The character of the communication trenches is also a factor of importance; they may, for instance, be habitually flooded except in the driest weather because the German trenches lie sufficiently high and sufficiently near to allow them to pump down on the British trenches as much water as they please.

At other places the trenches may at all times offer an easy route for evacuation of casualties, but are so long, say upwards of two miles, that the journey of a patient down them necessarily absorbs considerable time.

Finally, there are spots where it is comparatively easy to get the patients from the fire trenches to the advanced dressing station, but not any further, with promptitude because there is no place near the advanced dressing station at which it is possible to keep an ambulance waiting, and consequently it has to be fetched.

The writer is personally acquainted with places which exemplify each of these statements, and the general list of determining factors could doubtless be extended. The net result is that already indicated—namely, that the time elapsing between the moment that a patient is hit and that of his arrival at the hospital where he is to be treated is liable to great variations not only at different parts of the line but at one and the same spot. There was, for example, at work till quite recently an institution which sometimes got its abdominal cases on the operating table within as little as an hour from the time at which they were struck, and sometimes not for a dozen hours. This was despite the fact that it lay within a quarter of an hour's drive of the trenches which it served, and that these could commonly be approached and left in daylight.

The foregoing, though the most important, are not the only circumstances which help to bring about great variation in the lapse of time between the receipt of an abdominal wound and the undertaking of any consequent operation. All abdominal wounds cause more or less shock, and the shock is liable to be increased by many circumstances, including exposure to wet and cold. Some surgeons are disposed to operate as soon as they possibly can, despite the existence of even profound degrees of shock. Others prefer to wait for some time, adopting meanwhile any measures they deem calculated to reinforce the patient's vitality. These always include the changing of wet clothing, keeping the patient in a warm atmosphere, and making him as comfortable as his injuries permit.

Everywhere now opinion seems on the whole to favour habitual operative interference in all cases of abdominal wounds. It is hardly disputable that cases are saved which would certainly have died under the starvation or expectant treatment formerly in favour, but it is by no means certain that the change of practice spells as much real progress and saving of life as might be assumed from some of the accounts that have been published.

Individual attitude towards the work varies greatly. Some of those who have had most experience of it regard it as of a most depressing and disappointing character, while others are buoyantly enthusiastic. The explanation seems to be that the depths of this very special class of surgery have not yet been fully plumbed, with the result that some men are unduly influenced by the endless cases in which a favourable prognosis eventually proves unjustified, while others are too ready to generalize from the apparently hopeless cases which proceed to convalescence without a check.

The stretcher used for the transport of abdominal cases whenever possible has a back support and a thigh support, relaxation of the recti and other abdominal muscles being thus secured.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed.

The cruiser H.M.S. *Hampshire*, which was carrying Lord Kitchener and his staff on a mission to Russia, was blown up by a mine off the west coast of the Orkneys on the evening of June 5th, and sank with all but twelve of her complement of some 650 men. Among thirty-eight officers who perished were three medical officers—Fleet Surgeon P. G. Williams and temporary Surgeons H. F. McNally and H. G. Chaplin.

Fleet Surgeon Penry Garnons Williams was the son of the late Prebendary Garnons Williams, of Abercarnlais, Brecon, was educated at St. Thomas's Hospital, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1899, and entered the navy the same year. He was promoted to staff surgeon on May 15th, 1907, and to fleet surgeon last year. Prior to his promotion he was serving on H.M.S. *Amphitrite*.

Temporary Surgeon Hugh Francis McNally was the son of Mr. Nicholas McNally, late Principal of Raglan Street Boys' School, Belfast. He was educated at St. Malachy's College, and served his apprenticeship as a chemist, after which he entered Queen's University, Belfast, where he graduated M.B., B.Ch., and B.A.O. in 1915. He was a member of the University O.T.C., and also of the Irish National Volunteers.

Surgeon Maurice H. de J. Harper, whose death on the *Queen Mary* was briefly noted last week, was 27 years of age, and was the son of a naval chaplain. He received his early education at the Pocklington Grammar School and Trent College, and when at Newcastle-upon-Tyne College of Medicine played cricket for his university and college. After joining the navy he was stationed for many months at Chatham Naval Barracks, was then appointed to H.M.S. *Thames* and about three months ago to H.M.S. *Queen Mary*.

Surgeon T. Mansergh Wood-Robinson, who was killed on the *Black Prince* as noted last week, was also the son of a naval chaplain. He was 25 years old and received his early education at Crediton and Portsmouth grammar schools. After the outbreak of war, while waiting for a commission, he held the appointment of house-surgeon at the Middlesex Hospital. He joined H.M.S. *Black Prince* in May, 1915. A short time ago he was awarded the Royal Humane Society gold medal for a gallant attempt to save the life of a man who had fallen overboard.

Casualties in the Naval Action of May 31st.

Since the casualty list was published on June 5th it has been reported that eight officers, mostly from the destroyers *Nomad* and *Nestor*, and about 170 men, were picked up by the Germans, and are prisoners, not killed, as was reported at first. Among the survivors are Surgeon-Probationers D. J. T. Oswald, of the *Nomad*, and A. Joe, of the *Nestor*.

ARMY.

Killed in Action.

Captain Walter Seymour Armstrong, R.A.M.C., of Monatha, Hythe, Kent, was killed in action on May 31st. He was the youngest son of the late Rev. William Armstrong, Vicar of St. Mark's, Dalston, Yorkshire, and was educated at St. George's Hospital, taking the M.R.C.S. and L.R.C.P.Lond. in 1903, after which he acted as assistant medical registrar at St. George's. He subsequently went to Newfoundland, where he was surgeon of St. Anthony's Hospital and surgeon in charge of the Indian Harbour Hospital and a Justice of the Peace. He received a commission as temporary captain in the R.A.M.C. towards the end of 1914, and served with the British Expeditionary Force in France in 1914-15, and subsequently with the Mediterranean Expeditionary Force.

Died of Wounds.

Lieutenant-Colonel A. W. Tanner, commanding the 10th Canadian Field Ambulance, died from wounds received on June 3rd. He was born at Watford, Ontario, in December, 1875, graduated at Toronto University in 1899, and settled in practice in Moosomin, Saskatchewan. There he rapidly made his mark as a general practitioner and most capable surgeon. In 1910 he joined the 16th Canadian Light Horse, allied with the 16th (the

Queen's) Lancers, and within a month of the beginning of the war was given his lieutenantancy in this brigade. From being a combatant officer he transferred to the C.A.M.C., and last year was appointed A.D.M.S. of the 10th Canadian Military District, which included the Provinces of Manitoba and Saskatchewan. As such he was in medical charge of the Sewell Camp in Manitoba, and later was largely instrumental in bringing together and establishing the 10th Field Ambulance. This unit arrived in England on March 13th, 1916, and within a month was at work at the front. Here Colonel Tanner immediately impressed all with whom he came into contact as a most capable officer with administrative abilities of the first order. His death is a very distinct loss to the Canadian Army Medical Service.

Surgeon-General Carleton-Jones, D.M.S. Canadian Expeditionary Force, writes: "Lieutenant-Colonel Tanner I have only known a short time, since he joined the Expeditionary Force in England, but from what I saw of his work in England and in France, I was particularly struck with his natural ability for military medical work. I feel his loss very much, as it means that the service is deprived of a most capable and useful officer."

Wounded.

Captain D. A. R. Haddon, R.A.M.C. (T.F.).
Captain J. J. Jamieson, Canadian A.M.C.
Captain J. A. Reid, Canadian A.M.C.
Captain C. F. White, R.A.M.C.
Lieutenant E. V. Sullivan, R.A.M.C.

Missing.

Captain F. S. Park, Canadian A.M.C.
Captain W. R. W. Haight, Canadian A.M.C.

Died on Service.

Temporary Lieutenant G. S. Engineer, I.M.S., was reported as having died on service, in the casualty list published on June 8th. His commission was dated July 24th, 1915.

Temporary Captain Elfred Chalmers Austin, R.A.M.C., died at West Didsbury, Manchester, of septicaemia following pneumonia and empyema, on June 5th, aged 39. He was educated at St. Mary's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1899, subsequently taking the F.R.C.S. at Edinburgh in 1903. After acting as resident obstetric officer at St. Mary's Hospital, house-physician to the Leicester Infirmary and Fever House, and assistant medical superintendent of the Kensington Union Infirmary, he went into practice at Barnard Castle. About four years ago he was appointed medical superintendent of the Hope Hospital, Salford. In March, 1915, he was appointed by the Manchester Guardians medical superintendent of the Withington Institution Hospital and of the Dr. Rhodes Memorial Home, Withington. The Withington Hospital was soon after transferred to the military authorities as a hospital for sick and wounded soldiers, and he received a temporary honorary commission as captain in the R.A.M.C. while in charge of it. He was a hospital administrator of great experience, keenly interested in surgery, and an operator of repute. He leaves a widow and two young daughters.

PRISONERS OF WAR.

On June 7th the War Office published a list of the officers taken prisoners by the Turks when General Townshend's force surrendered at Kut-el-Amara in April owing to want of food, after enduring a siege of five months. The total number of names given was exactly 200, and it was stated that a few more would follow. Besides General Townshend himself, there were five other general officers in the force: Major-Generals Sir C. J. Melliss, V.C., K.C.B., and W. S. Delamain, D.S.O., and Brigadier-Generals H. D. Grier, C.B., W. G. Hamilton, C.B., D.S.O., and G. B. Smith, C.B. Among the 200 officers were twelve officers of the R.A.M.C. and twenty of the I.M.S.

R.A.M.C.

Lieutenant-Colonels J. Hennessy, C.B., and H. O. B. Browne-Mason.
Majors E. V. Aylen, E. Bennett.
Captains A. S. Cane, C. E. M. Jones, A. T. J. McCreery, R. K. Mallam, L. Murphy, T. E. Osmond, and J. Startin.
Lieutenant F. T. Simpson.

I.M.S.

Colonel P. Hehir, C.B., Principal Medical Officer.
 Majors S. Anderson, C. H. Barber, W. M. Pearson.
 Captains L. A. P. Anderson, D. Arthur, R. C. Clifford,
 S. C. R. Haughton, H. H. King, J. S. S. Martin, K. K.
 Mukerji, C. Newcomb, M. L. Puri, and F. H. Salisbury.
 Captain G. O. Weston, I.S.M.D.
 Lieutenants N. K. Bal, R. V. Martin, and W. C. Spackman.
 Temporary Lieutenants A. Y. Dabholkar and N. R. R. Ubhaya.

DEATHS AMONG SONS OF MEDICAL MEN.

Austen, Mark, Midshipman H.M.S. *Queen Mary*, only son of Fleet Surgeon Austen, R.N., killed in action, May 31st, aged 16.
 Bates, Edwin Raymond, Midshipman H.M.S. *Indefatigable*, elder son of Dr. Bates, of Lingfield Road, Wimbledon, killed in action on May 31st, aged 17. He entered Osborne in January, 1912.

Cathcart, F. J., Lieutenant R.F.A., aged 21, who was killed in action in Mesopotamia on June 4th, was the only son of Mr. C. W. Cathcart, Senior Surgeon to the Edinburgh Royal Infirmary. He was an engineering student at the University of Edinburgh, where he was a member of the artillery unit of the O.T.C. His commission was dated August 26th, 1914. Before going to Mesopotamia he had seen service at Suvla Bay.

Cooper, William Francis Reginald Ashley, Midshipman H.M.S. *Indefatigable*, only son of the late Dr. T. G. Duncan Cooper, killed in action on May 31st, aged 18.

Faulkner, Robert Irvine, Lieutenant H.M.S. *Black Prince*, younger son of Dr. C. I. Faulkner, late of Escrick, Yorkshire, killed in action on May 31st. He joined the navy as a midshipman in May, 1904, and became lieutenant in July, 1908.

Flemming, Thomas Frederick Stewart, Lieutenant H.M.S. *Invincible*, aged 22, killed in action on May 31st, was the eldest son of Dr. Charles Flemming of Bradford-on-Avon.

Hind, Charles Raymond, Second Lieutenant South Staffordshire Regiment, second son of Alfred E. Hind, F.R.C.S., of Portland House, Jersey, killed in action on May 30th, aged 22. He was educated at Laleham School and at Radley College, where he was captain of the eleven, and had been a medical student at Pembroke College, Cambridge, for two years, when the war began. He got a commission from October 3rd, 1914, and for a year had commanded a brigade grenade company in France, having been mentioned in despatches.

Hodgson, Edward Thomas, Midshipman H.M.S. *Invincible*, younger son of Dr. Hodgson, of Alresford, Hants, killed in action on May 31st, aged 17. He was a second term cadet at Dartmouth when the war began, and he went to sea. He had been present in the battles of Heligoland Bight and of the Falkland Islands.

Lydall, Rev. Cyril Wykeham, M.A., Chaplain H.M.S. *Lion*, son of the late Wykeham Hawthorn Lydall, M.D.Lond., killed in action on May 31st by a shell which struck H.M.S. *Lion* in the recent action. He was born in 1873, and was educated at Bradford and Worcester College, Oxford. He had held previous commissions as chaplain in the *Minerva* and the *Swiftsure*. He was to have been married on the Monday following the action to Miss Grace Clarke, of Newcastle House, Nottingham. He was a nephew of Lord French.

Matthews, Humphrey, Lieutenant Royal Navy, lost in H.M.S. *Hampshire* on June 5th, aged 23, son of Valentine Matthews, Colonel late R.A.M.C. (Vol.).

O'Brien, Hugh Rivers Hamilton, Captain Royal Field Artillery, only son of Lieutenant-Colonel J. O'Brien, I.M.S. (retired), of Newstead, Instow, North Devon, killed in action on June 1st, aged 25. He was born in August, 1890, got his first commission in December, 1910, and became lieutenant on December 23rd, 1913.

MEDICAL STUDENT.

Surgeon-Probationer Robert Walker (H.M.S. *Shark*) was an Australian. He was in his fourth year as a student in medicine at the University of Edinburgh. He had won the Vans Dunlop scholarship in anatomy, the John Aitken Carlyle and the Mackenzie bursaries in anatomy, as well as the Cunningham memorial medal presented to the most brilliant student of the year in anatomy. He had in addition won eight medals in other subjects at the university.

NOTES.

FRENCH AND RUSSIAN PRISONERS IN GERMAN CAMPS.

A new arrangement which came into force on June 6th will henceforth ensure a regular distribution of 2 kilos of bread a week to all French prisoners in Germany. The bread ration provided by the German Government is 300 grams a day. The consignments of food-stuffs and clothing will continue as heretofore. All the French departmental organizations for aid to prisoners have been invited to group themselves into a national federation, and this organization, which has its head quarters in Paris, has undertaken to manage the bread supply. In this it will be helped by the French Government and by the International Red Cross Bureau in Geneva. The Federation has obtained certain guarantees. In each camp a delegate may correspond directly and without control with the Federation to inform it as to the regularity of delivery. A further control will be exercised by the neutral embassies. The German

Government has authorized the transport of collective consignments by express. It has also undertaken henceforth to furnish the exact numbers of French prisoners in each camp.

There are many complaints in the French papers about the ill-treatment of French prisoners in German camps. It is said that the sick are forced to work before they are well. *Le Journal* of June 5th published the statement of a soldier repatriated from Gardelegen on account of cancer, which he attributes to a blow in the stomach with the butt end of a rifle when he was suffering from a wound. At Erfurt, a month and a half before the repatriation, ten severely wounded men were left behind in huts lying on mattresses without any care; two of them suffering from tuberculosis died. Every pretext is seized upon for torturing the men and inflicting on them fresh sufferings and privations. A letter from a prisoner to his father is quoted in which the writer says that he and his fellow captives have to work from 7 a.m. till mid-day and from 1 to 6 p.m. on starvation diet. He adds: "Frankly, they try to kill us." To mislead public opinion the Germans continue to send out lying reports as to the treatment of the prisoners in France. The reports of neutral delegates as to the depôts in Brittany which they have recently visited testify to the excellent impression made upon them. At Chateaufort, where officers are interned, the delegate reports that "the state of the camp and of the prisoners is excellent." As to the Russians, there is abundant evidence of the bad treatment to which they were subjected by their German gaolers. The latest is given by the *Amsterdam Telegraaf*, which is quoted in the *Times* of June 10th as saying that some Russian soldiers who had arrived in Holland from German prison camps stated that during the sixteen months they were in captivity they did not taste meat. Their food consisted of potato soup and 7 oz. of bread daily. One of them said that nevertheless their treatment of the matter of food was much better than that of the British prisoners, many of whom fell ill.

MEDICAL OFFICERS WANTED.

The Scottish Women's Hospitals for Foreign Service.

Applications are invited from medical women for the posts of radiographers and bacteriologists in the Scottish Women's Hospitals. An honorarium at the rate of £200 per annum is granted, and uniform, board, and travelling expenses are provided. Application should be made to the Honorary Secretary, Personnel Committee, Scottish Women's Hospitals, 2, St. Andrew Square, Edinburgh.

England and Wales.

WAR-TIME SANITATION.

A CONFERENCE held at the house of the Royal Sanitary Institute of London last week was attended by a large number of medical officers of health and other delegates from nearly one hundred local authorities to discuss sanitary administration under war conditions. It was opened by the Lord Mayor of London, who was followed in the chair by the Mayor of Westminster; on the second day the meeting was presided over by Mr. Leslie Scott, K.C., M.P.

Economics in Health Departments.

At the first meeting, on June 9th, a discussion on the maintenance of the standard of municipal sanitation during the continuance of war conditions was introduced by Mr. H. Percy Boulnois, M.Inst.C.E., and Dr. James Wheatley, Medical Officer to the Shropshire County Council. Dr. Wheatley considered that child welfare and the medical inspection of school children should be maintained in all essentials. In other respects economies might be effected in health departments; work of the nature of original investigation might be dropped, and a certain amount of inspection eased off. He urged that action, with regard to conditions injurious to health, should be of a more summary and preventive character than at present; the creation of a nuisance, and not persistence in it after warning, should be the offence. Generally speaking, the measures for the prevention of infectious diseases should not be relaxed, and in some directions should be strengthened. Bacterial examinations necessary for the diagnosis of such diseases should at all costs be maintained. As to tuberculosis, it would be well to concentrate upon preventing the spread of the infection, and the M.O.H. should have power to cause the removal to hospital of any patient who was a grave danger to his household and to the public. Dr. Wheatley's further suggestion that, in the absence of other accommodation, boards of guardians should be compelled to provide for advanced and dangerously infective cases of phthisis by means of temporary shelters in connexion with the work-houses, was criticized by one or two subsequent speakers.

Much of the discussion centred around the question of disposing of house refuse. Mr. Boulnois, in his opening paper, expressed the opinion that though it would be false economy to interfere with the regularity of the refuse collection, the householder might do more in the way of burning refuse, and separating refuse which had an economic value. Dr. J. T. C. Nash (Norwich) suggested that three receptacles should be provided—one for green-stuff, a second for bottles and pots, and a third for other waste materials—and Dr. H. Kerr (Newcastle) held that a local by-law might be framed making it incumbent upon the householder to burn his own refuse. In reply to the objection that in many houses now there were only gas fires, Mr. Boulnois suggested that a simple domestic cremator might be designed, to be attached either to a gas or coal kitchen range. Major A. J. Martin urged that there would be no hardship in making the civilian do with regard to his refuse what the soldier had to do in the camp, and suggested that men ineligible for military service should be compulsorily put to scavenging or other public duty. Lieutenant-Colonel Herbert Jones (Hereford), speaking as one who had recently exchanged civil for military service, said that nothing struck him more in the transition than the rapidity with which reforms were accomplished in camp, as compared with the long delays in civil work. A resolution was passed unanimously requesting the Council of the Institute to consider at the earliest moment what temporary extension of legal powers was necessary to economize labour in the public health service and to make it more efficient.

The Administration of the Mental Deficiency Act.

At the meeting on June 10th Dr. A. Brown Ritchie, the medical officer of the Manchester Education Committee, opened a discussion on the administration of the Mental Deficiency Act. In dealing with the rule that all children certified as mentally defective should be kept in the special schools until 16, he said that a considerable number of them were as far advanced at 14 as they would be at 16, and there was no reason for keeping them at school until 16 unless some special training was provided during the last two years. He considered that the teacher's evidence was of great assistance in framing a diagnosis of mental deficiency or backwardness, but did not sympathize with the agitation that the teacher should take a higher position than that of a witness before the medical assessor. While he had always taken advantage of the information given by teachers, he could not see the value of a joint certificate in which the teacher and doctor shared the responsibility. Some one authority must certify the mentally defective. Mr. Leslie Scott, M.P., thought that the true policy would be to educate in the special schools those children who were likely to become more or less self-supporting citizens in after-life. Dr. Veitch Clark (Croydon) referred to the great difficulty of defining educability and non-educability, and preferred a triple classification—educable, trainable, and non-trainable. He did not think it was possible to look for any solid advance by means of home supervision, and in the country just now private guardianship of mentally defective children was practically non-existent. Dr. G. E. Shuttleworth (London) urged that there should be "backward" schools or classes in which children who were not decidedly but only presumably defective could be kept under observation before being certified. Dr. J. Oldershaw (Wallasey) said that the non-educable class of children ought to be handed over by the education authority to the mental deficiency committee, and suggested that the Government would do well to form a kind of non-criminal Borstal institution. Another speaker stated that at Brighton, under the Guardianship Society, defectives had been placed out with respectable families, and were visited once a fortnight, and by the doctor once a quarter, employment being found for them as far as possible.

BY-LAWS FOR MESSAGE ESTABLISHMENTS IN LONDON.

At the meeting of the London County Council on June 6th the by-laws which have been framed for massage establishments, as provided by the London County Council (General Powers) Act, 1915, were submitted and approved. These by-laws, which are framed for the purpose of preventing immorality, lay down a very strict system of registration and supervision, and, with regard to records,

it is made necessary for each registered person to show on demand all details with regard to his assistants and fees, as well as full particulars of every case of remedial treatment, with the name and address of the medical practitioner (if any) by whom or at whose instance such treatment was prescribed, the name of the person giving such treatment, and the sex of each patient. The definition of a massage establishment is a place used "for the reception or treatment of persons requiring massage, manicure, chiropody; light, electric, vapour, or other baths or similar treatment," but hairdressing establishments, where massage is confined within certain limits, have partial exemption. The chairman of the Public Control Committee stated that up to the present the Act had proved very successful, and the proportion of places suspected of being objectionable was very small.

Scotland.

WOMEN MEDICAL STUDENTS AT EDINBURGH AND GLASGOW.

THE necessity for providing further accommodation for the largely increased numbers of women studying medicine both in Edinburgh and Glasgow is engaging the attention of the medical teachers in the two cities. At the meeting of the Glasgow University Court, on June 8th, Principal Sir Donald MacAlister stated that he had to ask authority to make some additions to the equipment of Queen Margaret College, especially for students of medicine; congestion was already evident in the departments of anatomy and chemistry. He was unable to state what the cost would be, but as the number of women students had doubled during the year it was necessary to face the situation. The extension proposed would take the form of internal arrangements. The request was granted. In Edinburgh matters are somewhat different and it is possible that more radical changes may be required. Some three years ago (see BRITISH MEDICAL JOURNAL, October 25th, 1913, p. 1109) new anatomy rooms were provided for the Edinburgh School of Medicine for Women, the institution whose lecturers are recognized by the University as the teachers of the women students in Edinburgh. It was then thought that sufficient accommodation had been provided for many years. The phenomenal increases of the past two years have thrown all such anticipations out of gear, and the lecturers of the School of Medicine for Women are approaching the University Court with a view to a conference at which the whole question of the relations existing between the University and the women training for graduation in the School of Medicine could be considered.

FRENCH PROFESSORS IN EDINBURGH.

The French professors who have been visiting universities in Great Britain during the last few weeks were received in the Senate Hall of the University of Edinburgh on June 8th by the Senatus Academicus.

Sir Thomas R. Fraser, as senior professor, presided, and expressed the gratification of the Senate in receiving visitors who represented so many of the higher educational and academic institutions of France, not of Paris only, but of Lyons, Grenoble, Clermont, Montpellier, Nancy, and Poitiers. The visit, he said, recalled the close relations of friendship and co-operation that had existed between France and Scotland for many centuries. The desire that that relation should be maintained had been shown by the formation of the Franco-Scottish Society. There had, however, been no formal or official visit of French professors to Edinburgh since April, 1884, when the university celebrated the tercentenary of its foundation, and received through their numerous representatives the congratulations of practically every civilized nation and educational institution in the world. The university regretted that the distorted arrogance of some of these nations, and even of their most educated classes, had disappointed the full expectations of friendship then originated. This made it all the more a cause for rejoicing that the bond of union between many of these nations, including France, had been unbroken, and, indeed, drawn closer by the

momentous events of the recent past. Sir Thomas Fraser went on to sketch the development of the university since 1884. The number of professors had increased from forty-six to fifty-nine, and of lecturers from three to ninety-four. Practical instruction in research was then scarcely recognized as a part of higher education; now the greater part of the much-enlarged accommodation of the university was occupied by well-equipped laboratories. Unfortunately, however, the full life and activities of the university could not at present be exhibited, for the requirements of the devastating war in which, with its gallant allies, the country was engaged against a ruthless and unchivalrous enemy—the patriotism of its alumni and teachers—had depleted the number so much that while the matriculated students in 1913-14 numbered 3,283, in the present session the number was only 1,797. This number would be further reduced in the next session, as all eligible students would be required to give their services to the State, except those in the fourth and fifth years in the Faculty of Medicine. Before the passing of the Military Service Act 4,500 graduates and students had joined the services, or 1,217 more than the total number of matriculated students, both men and women, in the session 1913-14. Of these, at least 170 had been killed in action or otherwise in war service, 126 had been wounded, 2 were missing, and 8 were prisoners. They had acquitted themselves well, as military honours and decorations had been conferred on upwards of 77, while other 90 had been mentioned in dispatches. Other two members of the university had met with an untimely end in the deplorable catastrophe that overtook H.M.S. *Hampshire*—namely, Lord Kitchener and Sir Hay Donaldson, a member of his staff. Lord Kitchener's death added to the sorrow and academic gloom still remaining after the death of their late greatly distinguished Principal, Sir William Turner. They had now to lament the loss of their Lord Rector. These bereavements, as their guests would understand, had led to some curtailment in the expression of their hospitality, but, he was sure, not in the warmth and cordiality of their welcome. After dwelling on the unalterable determination of the empire and its allies to continue the task imposed on them of curbing the arrogant assumptions of their inhuman Germanic enemy, Sir Thomas Fraser went on to refer to the war of commercial and manufacturing industry which would follow the other war, and upon which the fate of nations would largely depend. Our educational system and methods, he said, would have to be remodelled to increase the facilities for advanced instruction throughout a wider range of the community than was now reached. A lesson which the war had taught was that expansion was required not only in general education, but especially in science and technology, in finance and commerce and modern languages, in the physical training of the body, and perhaps also in mental and moral discipline.

Dr. Joubin, Rector of the Lyons Academy, who responded, said that France also was mourning Lord Kitchener. He and his colleagues, he said, had been touched by the cordial welcome they had everywhere received; they had visited both old and new universities, and had been greatly impressed by everything they had seen. The empty classrooms had their counterpart in France, where everyone had gone to the war. He concluded by referring to the close and old union between Scotland and France, and expressed the hope that the exchange of students which had continued since the Middle Ages would go on after the end of the war, for the two countries had much to learn from each other.

In the evening the visitors were the guests of the Scottish branch of the Franco-Scottish Society at an "At home" in the Kintore Rooms, where they were received by Lord Strathclyde, president of the branch.

Glasgow was visited on June 8th and 9th, and Principal Sir Donald MacAlister, K.C.B., addressed the French professors, who were shown over the University, Queen Margaret College, and other places of interest.

RED CROSS AMBULANCE TRAIN.

There was a large attendance of Red Cross bearers at a drill held at the Aberdeen Joint Station on June 11th. Mr. Bennett Mitchell, Red Cross transport officer, said that on June 10th the Red Cross had the first ambulance train to deal with without any aid from the R.A.M.C. They had

the maximum of cot cases, and the number of miles run amounted to 244. The time occupied was sixty-five minutes. Sir Alexander Ogston, who has enrolled himself as a volunteer, said it was necessary to be ready to deal with 470,000 wounded and sick at the lowest computation on the side of the Allies within the next twelve months. The work done at the train was such as those engaged in it might be proud of; but even if the 470,000 were dealt with by this one train at the same rate without a halt, day or night, it would take seven months to clear the whole into the hospitals.

Ireland.

INFANT AND MATERNAL WELFARE.

A COUPLE of months ago we gave some account of an inquiry instituted by the Carnegie United Kingdom Trust into the present position with regard to infant and maternal welfare, with special reference to the provision made, or in immediate contemplation, in various areas. As was there indicated, the inquiry instituted by the Executive Committee is of a comprehensive character, the desire being to obtain the fullest information, as to the existing provision, as to the legislation which exists for governing the administration of such centres, and as to the extent to which the municipal authorities have availed themselves of the powers they possess. After obtaining such full information the Executive Committee will consider what steps, if any, the trustees of the Carnegie Fund can take to assist in the solution of the problems which arise, the intention of the trustees being that their efforts shall not supersede, even in a small measure, State or municipal endeavour. It was recognized, however, that there may be some directions in which financial assistance may prove useful in encouraging developments which might not otherwise be attempted. As was stated when the matter was first noticed in these columns, Dr. E. W. Hope, M.O.H. for Liverpool, is supervising the inquiry for England and Wales. Dr. Leslie Mackenzie is discharging the same office for Scotland, and the trustees have secured the assistance of Dr. E. Coey Bigger, of the Local Government Board in Ireland, for the preparation of the report for Ireland.

The Local Government Board in Ireland has addressed a circular letter to the clerks of county boroughs and urban districts drawing attention to the operation of the Notification of Births (Extension) Act, 1915, which contains provisions enabling local authorities to make arrangements for attending to the health of expectant mothers, and nursing mothers, and of children under 5 years of age. In view of the considerable incidence of infant mortality in urban districts in Ireland, the problem of protecting infant life is one which deserves the serious attention of local authorities, and the fact that a grant of £5,000 in aid of approved schemes for maternity and child welfare has been included in the estimates to be submitted to Parliament will no doubt serve as an additional inducement to take action. Any scheme should, in the Board's opinion, include not only the care and supervision of children in the first year of life, and up to the age of 5 years, but should aim at securing improved antenatal and natal conditions.

Home Visiting.—The work of home visitation is one to which the Board attaches very great importance, and the first step should be the appointment of an adequate staff of qualified health visitors.

Maternity Centres.—In the case of the larger urban areas, it would be desirable to provide maternity centres to which expectant mothers and mothers with infants and young children could be referred for advice and treatment. Such centres should be under the charge of a medical officer and qualified nurse; and careful records kept for which the medical officer should be responsible.

Midwifery Facilities.—The scheme should further include suitable provision for medical and midwifery attendance for necessitous women not entitled to benefit under the National Insurance Acts or in receipt of assistance from the Poor Law authority.

Day Nurseries.—For the care of the young children of working women necessarily absent at work, day nurseries might, in industrial districts, be established. Definite fees should be charged to the mothers, sufficient at any rate to cover the cost of all food supplied.

The Board considers that as far as possible each sanitary

authority of an urban district should, in consultation with the medical officer or medical superintendent officer of health, undertake the organization of a scheme of maternity and child welfare for its district, having regard to the local circumstances and requirements. It is not suggested that the sanitary authority should necessarily institute and control all the arrangements; it is, on the contrary, hoped as a preliminary step the sanitary authority will get into touch with all the local associations and institutions dealing with matters connected with maternity and child welfare and will fully utilize their services.

Correspondence.

IMPORTED SYNTHETIC DRUGS.

SIR,—I agree that chemical industry will need protection during the next few years. Many of the drugs imported so largely can be produced here, but we have much to learn and a long way to travel before our chemists can put a beautiful packet of sodium salicylate at 3s. a pound on the market. Of course, it is well known that many of these drugs are by-products, and it would pay the Germans to give them.

We ourselves are largely to blame. We have played their game. We general practitioners have slavishly followed hints given by the specialists. A drug once used at the bidding of the great man becomes a regular item on our list.

Personally I have better results in treatment during the last two years than ever before. I have tried to get my patients better by a more careful consideration of all the circumstances—rest, simple treatment, and every care in diet. I have used less sodium salicylate and other antipyretics of similar nature in two years than in any two months previously.

I honestly believe that more harm is done by over-treatment than the reverse. Two of my young friends in the army, who before they joined would have never forgotten to take their tablets of phenacetin even on holiday, took some to France. I saw them both a few weeks ago, looking very fit. "Have you finished your tablets?" I asked. "Have never seen them," was the answer.—I am, etc.,

June 6th.

M. B.

"THE SOLDIER'S HEART."

SIR,—May I support Dr. Lyon Smith in his desire to know from Sir James Barr how he eliminates "the many toxæmias to which Dr. Harry Campbell refers" from the causation of "soldier's heart"? Practically every soldier is the subject of some degree of dental or naso-pharyngeal sepsis, and to me it seems clear that till this all-pervading possible causation is eliminated Sir James Barr's case stands non-proven.—I am, etc.,

London, W., June 10th.

J. G. TURNER.

FEES OF LOCUMTENENTS.

SIR,—May I suggest a more practicable method of dealing with the locum question than that proposed by "M. W. B." in your issue of June 10th, p. 838? Surely at such a time as this an opportunity is offered to abolish a great deal of the mutual distrust and suspicion that have been so prevalent amongst us in the past. In most cases a professional neighbour, with his local knowledge, is a much better substitute than a regular locumtenent. Even when reliable the average locumtenent is looked on with suspicion by patients, who often transfer themselves elsewhere. On the other hand, if Dr. A. is doing work for Dr. B. he is bound to hand over all patients to Dr. B. on the latter's return, and he will be encouraged by the fact that Dr. B. is to do his work in return, and will naturally do as he has been done by. Suspicion breeds suspicion and confidence begets confidence. A strong ethical committee would further assist matters, and strengthen those whose ethical conscience needs stimulating. I am aware that this system will not meet the case of unopposed practices, but I believe that it would be found to work satisfactorily in most places where there are several practices, and should be more extensively tried. It is a matter of mutual obligation, and needs only to be fairly and honestly carried out by both parties to the contract. Most men of experience have some

bitter experience of some locumtenent, and my own leads me to say (without any reflection on the numbers of able and conscientious men engaged in that class of work) "anything is better than risking patients' lives and the welfare of the practice to an unsteady locumtenent."—I am, etc.,

Minster, June 11th.

H. DOWNES.

SIR,—With reference to the complaint of your correspondent "M. W. B.," may I state that an impression that has unfortunately gained ground, that it is almost impossible to procure locumtenents and that the fees are £9 9s. or more, is quite at variance with facts? Since the war began many hundreds of vacancies have passed through my hands, and I am glad to be able to assert that, thanks to the loyal help of many men retired from practice and others ineligible for the army, the supply has so far been equal to the demand.

The fees at present obtaining are £7 7s. a week for normal practices, less if hospitality is offered to a wife or others. Somewhat higher fees are paid in manufacturing, north country, and colliery districts.

If, as your correspondent suggests, principals would refuse to pay excessive fees, the few men who are trying to take an unfair advantage of their country's difficulties would soon be brought to reason.—I am, etc.,

London, June 12th.

PERCIVAL TURNER.

The Services.

AUXILIARY R.A.M.C. WIDOWS AND ORPHANS FUND.

As was briefly mentioned in our last issue (p. 828) a meeting was held at the Royal Army Medical College on June 1st, 1916, to consider the desirability of establishing funds raised by voluntary contribution for the benefit of widows and orphans of officers and of other ranks of the Special Reserve, Territorial Forces, and Temporary Branches of the R.A.M.C. who serve during the war and who die without making sufficient provision for their families. The meeting was well and representatively attended.

Surgeon-General Sir Alfred Keogh, Director-General A.M.S., who was in the chair, described the means taken in the Regular R.A.M.C. to meet such contingencies, and expressed the opinion that it was desirable, now during mobilization, that the Auxiliary Branches of the R.A.M.C. should themselves at once make some effort to meet cases of distress in the families of both officers and men which must and will occur after the war. He left it entirely to the meeting to decide whether or no any such action should be taken, and if so, whether there should be a separate fund for each of the three branches—namely, the Special Reserve, the Territorial Force, and the temporary officers of the Regular service—or one fund and one committee embracing the three branches.

After considerable discussion, in which many of those present took part, Major Ewen Maclean proposed the following resolution, which was seconded by Colonel Culver James, and carried unanimously:

That a fund in connexion with the officers of the Auxiliary Branches of the R.A.M.C. be formed, and that a committee be appointed representative of the three branches to formulate a scheme and to report to a further meeting.

Colonel Westmacott proposed:

That the aforesaid committee be also requested to consider and report as to the possibility of establishing a general relief fund for the rank and file of the same forces.

This was seconded by Major A. C. Farquharson and carried unanimously.

The Director-General then asked the meeting to elect from among themselves a provisional committee to consider and report on the above resolutions, and the following officers were elected, with power to add to their number:

Colonel W. Culver James (T.F.), Colonel J. Atkins, C.M.G., Lieutenant-Colonel Sir John Collie, Lieutenant-Colonel H. H. Tooth, C.M.G. (T.F.), Major Ewen Maclean (T.F.), Major G. Newton Pitts (T.F.), Captain R. J. Stirling (S.R.), with Lieutenant-Colonel F. W. H. Davie Harris as Secretary, 124, Victoria Street, W.

The scheme formulated by the provisional committee will be considered at a meeting, to be presided over by the Director-General, at the Royal Army Medical College, Grosvenor Road, S.W., at 2.45 p.m. on Monday, June 26th. It is hoped that as many medical officers as possible of the Special Reserve, Territorial Forces, and those holding temporary commissions in the R.A.M.C. will attend.

Obituary.

CHARLES EDWARD FITZGERALD, M.D.,

EX-PRESIDENT ROYAL COLLEGE OF PHYSICIANS OF IRELAND,

SURGEON OCUList IN ORDINARY TO THE KING IN IRELAND; PROFESSOR
OF OPHTHALMIC SURGERY, ROYAL COLLEGE OF SURGEONS,
IRELAND.

THE death of Charles Edward Fitzgerald, occurring with unexpected suddenness a few hours after an operation on the afternoon of May 27th, has left a blank sense of loss amongst the medical profession in Dublin and amongst all branches of society there. This is particularly felt in the world of art and music in which he took the keen interest of an expert and connoisseur. In social relations no medical man of his time in Dublin exercised a greater personal charm than Fitzgerald, and he was regarded in many circles with feelings of the greatest affection and esteem.

He was the second son of Francis Alexander Fitzgerald, Baron of the Court of Exchequer, and was born in Dublin on February 9th, 1843. His professional studies were pursued at Trinity College, Dublin, and in the Paris School of Medicine, where he attended the clinic of Professor Galewski, then at the zenith of his fame. On Fitzgerald's return to Dublin he began to practise as an ophthalmic and aural surgeon, and shortly afterwards was associated with the late Sir Henry Swanzy as surgeon to the National Eye and Ear Infirmary in Molesworth Street. In 1875 he was appointed lecturer in ophthalmic surgery to the Carmichael School of Medicine, and in 1889, when the two schools were amalgamated, he became joint professor of ophthalmology in the school of the Royal College of Surgeons. For ten years he held the post of ophthalmic and aural surgeon to the Richmond Hospital; he resigned in 1883. In 1876 Fitzgerald was appointed surgeon-oculist in Ireland to Her Majesty Queen Victoria, and he held the same appointment during the reigns of King Edward VII and King George V—a period of forty years.

Fitzgerald took an active part in effecting the amalgamation of the two old ophthalmic hospitals in Dublin and erecting the Royal Victoria Eye and Ear Hospital, which is now such a credit to the Irish metropolis. Shortly afterwards he retired from hospital practice. He continued his large private practice with unflagging zeal till the day of his death, and was always ready and pleased to lend the aid of his extensive experience to his former colleagues in their hospital work.

We are indebted to Sir ANDERSON CRITCHETT, Bt., for the following tribute to Dr. Fitzgerald's memory:

In the short space of three years Dublin has had to mourn the loss of her two senior ophthalmic surgeons, Sir Henry Swanzy and Dr. Charles Fitzgerald. When the latter was last with us during the International Medical Congress in 1913, his buoyant spirits and other signs of

constitutional vigour gave hopeful promise to all those who loved him—and their name was legion—that his useful life might be extended far beyond the allotted span. We now learn with profound grief that these expectations have not been realized. The congress was held at the time when he was President of the Royal College of Physicians in Ireland, but we found him to be still the same genial, modest, self-effacing Charlie Fitzgerald who had won our hearts in the far distant long ago, and, like Duncan, King of Scotland, he "had borne himself so meek in his great office," that many who were present did not know that he was holding it until after his departure. In addition to many other distinctions, he had the exceptional honour of bearing office as surgeon oculist in ordinary in Ireland to three British monarchs, and I know that his services were always held in the highest esteem. His extensive practice and the intervention of the Irish Channel prevented him from coming to the meetings

of the Ophthalmological Society as often as he desired; but his visits were always welcome, for, in addition to the valuable information which he never failed to impart, he brought with him that bright mental atmosphere which was inseparable from his delightful personality, and which, alas! cannot be replaced.

ALBERTO RIVA, a distinguished Italian clinician, died recently at the age of 72. He was born at Piacenza in 1844, and studied medicine at Parma and Bologna, graduating in the latter university in 1866. In 1876 he obtained by competition the post of professor of pathology and clinical medicine at Perugia. In 1886 he was appointed professor of medical pathology at Pavia, and two years later was called to the chair of clinical medicine in the University of Parma, which he continued to occupy till his death. He was a very successful teacher and the author of writings on chlorosis, rheumatic infection, juvenile arterio-sclerosis, gastric neuroses, the influence of the nervous system on the symptomatology of heart disease, the pigments of the urine and faeces, the action of arsenic and iron on the composition of the blood, and

many other subjects. He gave much attention to the drainage of serous cavities, and his name is associated with apparatus for thoracocentesis and paracentesis. He was one of the founders of the Italian Society of Internal Medicine, and took a prominent part in the promotion of hygienic reform, notably in the campaign against malaria. In conjunction with Canali he made researches on ankylostomiasis in the province of Parma.

JOHN HAROLD, M.B., B.Ch., B.A.O. ROY. UNIV. IREL.,

PHYSICIAN, SS. JOHN AND ELIZABETH HOSPITAL, LONDON.

DR. JOHN HAROLD, who died on May 27th, at 65, Harley Street, after a long illness, was born in Dublin in 1860 of an old and highly respected Catholic family. His father, Mr. William Harold, was occupied with commercial metallurgy, and the son's tastes naturally turned to chemistry and were practically cultivated at an early age. But his ardent mind was unsatisfied with work of

[Photograph by F. A. Swaine,
London and Southsea.]

C. E. Fitzgerald

the kind, and he resolved to try his fortune in London. He worked in the dispensary of a medical practice, and spent his spare hours as a student at Charing Cross Hospital. From that time forward progress was steady, and progress ended in success. He was one of a distinguished group of Charing Cross men of the Eighties, winning the respect of his teachers, who quickly appreciated his bright young spirit, ability and industry; and at the same time those of his fellow students who were most intimate with him knew of his humble room in the depths of Bloomsbury, and of his labours in practical pharmacy in the long evenings after his hard day's work in the dissecting room and laboratories. Even before he qualified he was appointed assistant in several of the classes; and, when he had "passed" the Colleges, the post of house-physician under Dr. Henry Green and Dr. Mitchell Bruce, and in due course that of medical registrar and teacher of practical medicine fell naturally to him, as well as a more responsible position in the school. Presently he found himself engaged in the drudgery of serial medical literature and medical coaching, and thereupon he left his nest in Bloomsbury and the dispensing table for the district of Cavendish Square and a practice of his own. In the most determined fashion he did not rest until he had again and again gone to Dublin and returned a graduate with Honours of the Royal University of Ireland. Naturally, he had help from his old teachers, who knew the great value of the assistance which he gave them in return. Still, it was Harold's own character and qualifications that accounted for the position which he reached as one of the most successful family practitioners in London. There was his bright Irish manner and "ways," attracting and securing the respect and intimate regard of patients. The friends who knew him best were aware how much of his success came from his unselfish devotion to poor patients; his bread cast on the waters returned to him after many days. But, quite beyond these, his reputation and position were made by real ability, by knowledge of medicine properly gained, and by the thoroughness of his work. With all his popularity, he never became dependent on social or fashionable repute, but remained a student, ready to appreciate and employ with well-trained discrimination every increase of knowledge and every improvement in the means of diagnosis and treatment. If a complaint were ever heard from his patients it was that he was over-exacting. He always used the best. He spared no expense in respect of laboratory reports, radiographic investigations, nurses, consultations and operations. He would leave nothing undone that he considered right and possible. And so obedience to advice, strictly enforced, developed into confidence and loyalty, and then into personal regard and close attachment.

The last sixteen years of his life were a specially happy period because of his appointment as Physician to the Hospital of St. John and St. Elizabeth and member of the council. By none will his death be more deplored than by the Sisters of Mercy and his colleagues there. He was

also referee to the London Cremation Company and Honorary Physician to the Academy of Dramatic Art.

It is two years since Dr. Harold's oldest friends who watched his career with cordial interest began to note in him evidences of physical and nervous strain. With difficulty he was persuaded to rearrange and reduce his work. Then fell on him the cruel hand of the great war. His eldest son left Oxford for the front. His second son, a naval cadet of 15 only, was lost with H.M.S. *Hogue* on September 22nd, 1914. He was never himself again. He leaves a widow and two sons and two daughters.

J. M. B.

SAMUEL F. McLACHLAN, M.B., C.M.Glasg., J.P.
The death took place on June 9th of Dr. McLachlan of Longtown, one of the oldest and best known medical men in North Cumberland. Dr. McLachlan was a Dumfriesshire man, was educated at the University of Glasgow, and graduated M.B., C.M. in 1873. He settled in Longtown in 1879, and continued in practice there until failing health compelled him to retire in 1914. He held the post of M.O.H. for the Longtown district for over thirty years, and was keenly interested in sanitary improvements. He was also medical officer of the union, certifying factory surgeon, medical officer to the P.O. He was a member of the British Medical Association up to the time of his retirement. In the midst of the exacting demands of a large general practice he found time to keep himself abreast of the progress of medical science, and was a keen student of the best modern literature. He was essentially a cultured man, and took an active interest in the Longtown Literary and Scientific Society. He was a member of the United Free Church, chairman of the managers, session clerk, and trustee of the church. He was placed on the commission of the peace for the county of Cumberland in 1907, and regularly attended the sittings of the Longtown Petty Sessional Division. The large attendance at the funeral at Arthurat on June 12th from all parts of the district testified to the high esteem in which he was held. He leaves a widow and one son.

Last month there was laid to rest the remains of one of those quiet unobtrusive practitioners to whom the rural districts of Scotland owe so much, and whose name and fame are household words in the countryside. For thirty-six years, with the exception of a year or two practising in Birmingham, Dr. JAMES GILROY, of Waterbeck, Dumfriesshire, who graduated M.B., C.M.Glasg. in 1889, was the devoted parish doctor of Middlebie. An earnest student and an accomplished clinician, he early acquired the confidence of his patients, and his advice and help were much sought for in neighbouring parishes. He had high literary attainments, and was an occasional contributor to the columns of the JOURNAL. As a friend he was staunch and true. He was a widower, his wife and only child having died many years ago. Professor Gilroy of Aberdeen University, assisted by the local clergy, officiated at the

funeral, which took place amidst manifestations of the utmost sorrow and respect, and was attended by neighbouring fellow practitioners and representatives of all classes in the district. His place will be hard to fill, and when one thinks of the mossgrown gravestones in the quiet burial place of Caruthers, on the banks of the purling Kirtle Burn, it is with the thought that at last he has attained well earned rest and peace—the rest of the faithful and true, and the peace which passeth understanding.

DR. LÉON GAUTIER, who died on April 20th, was born at Geneva in 1853, and received his preliminary education at the gymnasium and academy of his native city. In 1872 he went to Paris to study medicine, and in 1877 won the post of *interne*, and worked under Hayem, Lancereaux, and Guyot. It was under the inspiration of Lancereaux that in 1882 he presented a graduation thesis on chronic absinthism, a subject as to which little was then known. On his return to Geneva he devoted himself chiefly to obstetrics. He was for a long time librarian and twice president of the Medical Society of Geneva. In 1902 he was elected a member of the Swiss Medical Commission, of which he was later vice-president. Although he qualified as *privat-docent* in the University of Geneva in 1899 he seems never to have delivered any lectures, but he made many contributions to clinical medicine, and especially to obstetrics. His most important literary productions, however, were in the domain of history. His chief work, *La Médecine à Genève jusqu'à la fin du XVIII^e siècle*, is based on researches in the archives of the city extending over twenty years. He also took a considerable part in the compilation of the history of Geneva by the Secretary of State, J. A. Gautier, and in that of the registers of the council of the city. Among his other writings are memoirs on the last epidemic of plague in Geneva, on the lepers in Geneva in the Middle Ages, on the diseases of Calvin, and reports on legislative subjects connected with medicine—the federal insurance laws, the federalization of midwives, the reform of medical studies, and alcoholism. Gautier took a very active part in the campaign against tuberculosis. In 1909 he was elected a member of the Grand Council of Switzerland, where he was often the only representative of the medical profession; he was a strenuous defender of its rights, and was always active in the promotion of measures of sanitary betterment. On the outbreak of the war he joined the International Prisoners Agency at Geneva, and did much valuable work for it.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

A MEETING of the Central Committee of the Fund was held on June 8th at the office of the *Lancet*, when Sir Rickman Godlee, the chairman of the Committee, reported the receipt, through the International Commission for Relief in Belgium and Mr. Herbert Hoover, of an acknowledgement of a cheque for £800 sent by the Committee for distribution to medical men and pharmacists in Belgium. The distribution had been made through the agency of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés. This sum was the first of three monthly donations of £800 which it had been agreed by the Committee should be transmitted to Belgium in the manner and for the purpose described. Mr. Hoover enclosed also for the consideration of the Committee a transcript of the proceedings of the Belgian Committee, which sufficiently showed the urgent need of the money sent and the wise way in which it was allocated. The Committee thereupon decided to continue sending these monthly grants for three more months. Professor H. G. Greenish was elected a member of the Committee, and will co-operate with Dr. Des Voeux in organizing the consideration of individual cases of distress of Belgian pharmacists in this country. The total receipts of the Fund up to June 8th were £19,250.

SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received since the last list was published are as follows:

	£ s. d.		£ s. d.
Dr. G. H. D. Carpenter (thirteenth and fourteenth donations— total £14) ...	2 0 0	South-West London Pharmacists' Association, collected by Mr. J. Krall ...	25 0 0
Mrs. Victor Williams ...	2 2 0		

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on June 8th, 1916, Sir W. Watson Cheyne, President, in the chair.

Court of Examiners.

Mr. R. L. Knaggs and Mr. Jonathan Hutchinson were re-elected on the Court.

Results of Examinations.

First Fellowship.—Eleven candidates were approved at the late examination.

Final Fellowship.—Diplomas were granted to the following candidates found qualified at the recent examination:

A. L. P. Gould, Temporary Surgeon R. S. Lawson, C. W. B. Littlejohn, F. D. Sauer, G. S. Milner.

Dental Surgery.

Diplomas of the Licence in Dental Surgery were granted to eighteen candidates found qualified.

Examiners in Anatomy and Physiology for the Fellowship.

The following were appointed for the ensuing year:

ANATOMY.—W. H. Clayton Greene, R. W. Reid, Gordon Taylor, W. Wright.

PHYSIOLOGY.—G. A. Buckmaster, J. Sydney Edkins, J. B. Leathes, A. Rendle Short.

Examiners under the Conjoint Examining Board.

Examiners in Elementary Biology.

ELEMENTARY BIOLOGY.—G. P. Mudge, W. G. Ridewood.

ANATOMY.—J. B. S. Fraser, A. M. Paterson, A. Thomson.

PHYSIOLOGY.—C. M. H. Howell, H. E. Roaf, G. A. Buckmaster (sub.), MIDWIFERY.—H. R. Andrews, J. S. Fairbairn, C. H. Roberts, G. D. Robinson.

PUBLIC HEALTH.—Part I: J. W. H. Eyre. Part II: Sir Shirley Murphy.

TROPICAL MEDICINE.—J. W. H. Eyre, C. W. Daniels.

Candidates for Election on the Council.

A meeting of the Fellows will be held at the College on Thursday, July 6th, for the election of four Fellows in the vacancies occasioned by the retirement in rotation of Sir Alfred Pearce Gould, Mr. W. F. Haslam, and Sir William Arbuthnot Lane, and by the death of Mr. Stanley Boyd.

Candidates.

Of the three retiring candidates—Sir A. Pearce Gould, Sir Arbuthnot Lane, and Mr. Haslam of Birmingham—the third alone seeks re-election. Six Fellows not already on the Council are candidates—namely, Mr. T. H. Openshaw, C.M.G., a Member in 1882, a Fellow December, 1886 (London Hospital); Mr. Raymond Johnson, Member 1885, Fellow December, 1888 (University College Hospital); Mr. John Murray, Member 1887, Fellow December, 1890 (Middlesex Hospital); Mr. Vincent Warren Low, Member 1891, Fellow December, 1893 (St. Mary's Hospital); Mr. Herbert Pendlebury, Member 1896, Fellow December, 1897 (St. George's Hospital); and Mr. Francis J. Steward, Member 1895, Fellow 1898 (Guy's Hospital). Thus seven Fellows will contest the four vacancies left by the three retiring members and by the death of Mr. Stanley Boyd.

Medical News.

THE Queen has become patroness of the Incorporated Society of Trained Masseuses. The society has been in existence for twenty years, and since the outbreak of war its members have done much work among the wounded.

AT a special meeting of the Section of Surgery of the Royal Society of Medicine to be held on July 12th at 5 p.m., Dr. Fred. H. Albee of New York will give a cinematograph demonstration on bone surgery, including bone grafts for Pott's disease, inlay grafts for fracture of long bones, and peg grafts for fracture of the neck of the femur.

MR. J. Y. W. MACALISTER, Secretary of the Royal Society of Medicine, desires to replace in the library of the Society the copy of Henry Lawrence's *Treatise on Hernia*, 1807, which has been destroyed by mice. He has tried the booksellers in vain, and would be grateful to any one who would put him in the way of finding a sound copy.

AT the annual general meeting in London of the Coroners' Society of England and Wales, Mr. F. N. Molesworth, solicitor, H.M. Coroner for the Rochdale Division of Manchester, was unanimously elected President for the ensuing year, vice Dr. F. J. Waldo, J.P., H.M. Coroner for the City of London and Ancient Borough and Vill of Southwark. Owing to the war, the usual banquet was not held, but the members of council were entertained at lunch by the outgoing president (Dr. Waldo).

THE Council of the Faculty of Insurance has appointed a committee to consider the report of the departmental committee on approved society finance and administration, and to advise on the whole position of the insurance scheme. Mr. John Hodge, M.P., will act as chairman, and three other members of Parliament have joined—Mr. Handel Booth, Mr. G. W. Currie, and Mr. J. W. Pratt. The committee also contains representatives of approved societies, of the Federation of Employers Provident Funds, and the chairman of the Manchester Insurance Committee. The committee, when complete, will include representatives of women's organizations.

DR. W. C. GORGAS, Surgeon-General of the United States Army, said recently that the United States would, in a few years, have an army of one million men, and would require at least 10,000 medical officers. He recommended the formation of a national conference of medical examiners, who should prepare questions to be set by State boards throughout the country. Candidates who passed this examination would be eligible for the United States Medical Reserve Corps, and would not be required to pass any other examination for the licence to practise. Each surgeon would be instructed in field duties, camp sanitation, and the foods suitable for different climates.

AT a drawing-room meeting last week in support of the South London Hospital for Women, Clapham Common, Sir Frederick Treves, who was the principal speaker, said that it was impossible to foresee what the full development of the woman doctor might be, or what limitations she might encounter, but it was evident that her first energies were rightfully directed to the treatment of her own sex. If the battle of the woman doctor was over, and the obstacles put in her way were becoming negligible, and the opportunities in front of her were increasing year by year, it was none the less true that she could not be said to have come into her own until hospital practice was more fully open to her. In hospital practice he (and now she) had the continual stimulus and safeguard of well-informed criticism. The other speakers were Lady Frances Balfour and Mr. Pett Ridge.

THE accounts presented at the usual monthly meeting of the Medical Sickness and Accident Society on May 19th showed a falling off in sickness in comparison with the same period last year, and the experience is below the expectation for the four months—an unusual feature for the spring months. It was reported that further sums had been invested in Exchequer bonds, making a total of £180,000 now invested in war stocks since August, 1914. Applications were reported from members for annuities under the new table which is now registered by the department, and is accordingly open both to members and non-members, and it is hoped will prove satisfactory and useful to the profession generally. The committee has decided that in future the society will pay the usual fee of £1 ls. for the medical examination of both new and additional proposals, the member to have the same right as hitherto of going to whom he pleases for such examination unless otherwise instructed by the society. Membership is still open to those taking temporary commissions in the R.A.M.C. or the Royal Naval Medical Service within certain limits with regard to amounts, as so far the committee do not consider that the casualties justify them in any way altering their previous decision in this matter. No extra premiums are charged to members of the two forces mentioned. All applications for prospectuses and further information should be addressed to the Secretary, Medical Sickness and Accident Society, 300, High Holborn, W.C.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Astology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (advertisements, etc.), *Astology, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

ACNE ROSACEA.

S. asks for suggestions as to the treatment of an obstinate case in a healthy working woman, aged 34, an abstainer from alcohol and, recently, from tea. The nose is much disfigured and the rash has extended down to the chin.

ANSWERS.

ATTENDANCE ON SOLDIERS BY CIVIL MEDICAL PRACTITIONERS.

THE note by "X. Y. Z." published last week, has brought up a number of other letters. Two correspondents state that their experience has been exactly the same—namely, that they have received no reply to applications made in proper form—and a third states that he has received no reply to a letter of inquiry. On the other hand, a correspondent states that though he has had to wait periods varying from one to four months after sending in his accounts, he has always been paid, though he has sometimes had to send a reminder. Another correspondent states that he has in the course of twelve months sent thirteen accounts for medical attendance to soldiers on furlough for varying sums, and that they have all been paid with satisfactory promptitude. A Major, R.A.M.C., asks whether "X. Y. Z." studied the regulations of the Royal Pay Warrant before sending his account. He would, this correspondent adds, have no claim on Government unless regularly appointed with the approval of an A.D.M.S. to attend the troops at contract rates.

LETTERS, NOTES, ETC.

PARAFFIN FOR LOUISINESS.

A NAVAL medical officer writes to express the opinion that the use of paraffin to get rid of lice in the manner suggested by Dr. B. Hall in the JOURNAL of June 10th, p. 837, might prove decidedly dangerous owing to the inflammability of the paraffin. He thinks that if the method is used at all a special warning should be given, for thoughtlessness or inexperience might lead to disastrous results.

MEDICINE AND THE NATIONAL VOLUNTEERS.

COLONEL JAMES CANTLE (Principal, The College of Ambulance, 3, Vere Street, London, W.) writes: In reply to a letter from Dr. Hildige (at p. 840, June 10th, 1916) in regard to ambulance instruction, I beg to say that classes for instruction of medical men have been held from time to time as the necessity arises. Medical men wishing to join should communicate with the secretary.

INADEQUATE MEDICAL EXAMINATION OF RECRUITS.

A CORRESPONDENT tells us that he has recently had to examine about thirty enlisted men alleged to be medically unfit. Among them were the following: (1) An undersized and badly-developed boy, weighing 93 lb. and measuring 30 in. round the expanded chest. The commanding officer reported that he was quite unable to march, bear his pack, etc. (2) A boy mentally deficient and unable to answer intelligibly even the simplest question. The commanding officer reported that he could not understand any order and walked about in a lost way. (3) Several men with very defective vision, for whom the oculist could do little, and some who were almost stone deaf. Even the most cursory examination, our correspondent states, made it apparent that none of these men would make efficient soldiers. Some of them had been in the army for two or three months and some for a shorter period. The military authorities, with no medical knowledge, had discovered, as quickly as could be expected of them, that these men were physically or mentally deficient. At the same time, the expense to the State must have been considerable. Such a state of things reflects, our correspondent thinks, very badly on the medical profession. He adds that the time spent in examining and discharging such men, who should never have been passed, involves serious waste of the time of medical men whose services are now so urgently needed.

BOLUS AND BULLET.

THERE is a story, duly put down in his tablets by that interesting diarist, Grant Duff, of an eighteenth century doctor who had been an apothecary and afterwards a physician at Bath. Being obliged to flee the country to escape his creditors he found his way to Berlin. There he contrived to get an audience of Frederick the Great, among whose good qualities was readiness to hold converse with all sorts and conditions of men. After questioning the doctor about his experiences the King said to him with true Teutonic tact, "You must have killed a great many people." "Not so many as your Majesty!" was the prompt reply. Frederick's degenerate descendant is said to be fond of rude jests at doctors, but we do not think that even his hardened conscience would now allow him to expose himself to the same retort.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posto restante* letters addressed either in initials or numbers.

Clinical Lecture

ON

THE RIGHT SIDE OF THE HEART AND
ITS RELATION TO OVERSTRAIN.

BY

WILLIAM RUSSELL, M.D., F.R.C.P.Ed.,

PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF
EDINBURGH, AND PHYSICIAN TO THE ROYAL INFIRMARY.

I ASK your attention to-day to the consideration of the clinical phenomena which, when correctly interpreted, enable us to arrive at certain conclusions as to the condition of the right side of the heart. At the outset we must recall the anatomical relations of the right heart. A frontal view of the heart is made up of right auricle and ventricle, and, at its left limit, of a strip of left ventricle about half an inch in breadth. The origin of the pulmonary artery, from that part of the right ventricle called the *conus arteriosus*, is in the second left intercostal space, while its position, when not thus situated, can often be precisely determined by palpation and auscultation, as these define the point at which the closure of the pulmonary cusps is best felt and heard. The right ventricle lies under the third, fourth, and fifth spaces, extending in the fifth space to within half an inch to an inch of the apex of the left ventricle. The right border of the heart forms an arc the convexity of which is to the right, and which lies in the third, fourth, and fifth intercostal spaces, extending in the fourth to an inch or one and a half inches from the right sternal border.

METHODS OF EXAMINATION.

Percussion.

The position of the left and right borders of the heart can be determined by percussion in the different intercostal spaces. The right border is the more difficult of the two to determine, but I have explained to you on previous occasions how it can be done, and I have warned you that a right border represented as a line along the sternum may be the border of the right lung, but cannot be the right border of the heart. The way you must look at this matter is, that the right border even of the normal heart is an inch or more beyond the sternum, and that you have to learn to find it. It is often considerably to the right of its normal limit.

Inspection.

Pulsation in the second left space is usually not due to the pulmonary artery, but to the *conus arteriosus*, and results from the fact that this part of the right ventricle dilates early, and that as it dilates it occupies the space carrying the origin of the pulmonary artery outwards and upwards, so that it may lie under the second rib, and be an inch or more to the left of the sternal border. Pulsation in the third, fourth, and fifth spaces, in the latter of these to within an inch of the apex, is always caused by the right ventricle, and all ideas based upon the phrase "diffuse apex beat" are erroneous. Such pulsation is a diffuse cardiac impulse, not a diffuse apex beat.

Auscultation.

In auscultating the heart the site of the apex of the left ventricle is auscultated, first, to determine the intensity of the first sound as produced by systole of the left ventricle; and, secondly, as the first step in determining whether a mitral lesion is or is not present. Having begun with the apex, and passing from it towards the sternum in the fifth, fourth, and third spaces, the loudness, faintness, or absence of the first sound is noted as an indication of the strength of the right ventricle. The old idea that the first sound as heard over the right ventricle was attributable to the left, as the thin-walled right ventricle was too weak to produce sound, has been more or less abandoned. The right ventricle is now credited with at least some part in the production of the first sound as heard over it. I, however, ask you to go further than that. I would advise you to look at this matter from a different standpoint—namely, that the first sound originating in the left ventricle and murmurs produced at the mitral orifice, as a rule and in the majority of cases, are not passed through the interventricular septum to the anterior wall of the right ventricle. The first sound as heard over the right ventricle

is therefore *not* produced by the contraction of the left ventricle. As regards murmurs produced at the mitral orifice, I again impress upon you that, as a rule, these murmurs are not heard to the right of where the ventricular septum forms part of the anterior aspect of the heart. We have frequently in the wards cases—and there are two or more such cases there now—in which loud systolic mitral murmurs are not heard over the body of the right ventricle, while they are well heard outwards and upwards to the left of the apex. Such cases must be accepted as the standard by which we are to judge of the true area of limitation as well as the direction of propagation of mitral murmurs. You must abandon any erroneous views you may have learnt that mitral murmurs are commonly conducted over the whole precordia—conducted even to the base. The rule is that when a systolic mitral murmur is audible at the apex, and a murmur of the same time is heard to the right of the ventricular septum, this latter is a separate and super-added murmur, and is tricuspid in origin. In cases of marked incompetence the tricuspid murmur is often heard so high on the sternum that it may be thought to be aortic in origin. When the murmur thus raises the question of its seat of production, it will be found that on making the patient sit up in bed the murmur will disappear from the manubrium sterni if it is tricuspid in origin, and will reappear when the patient lies down. An aortic systolic murmur does not disappear and reappear with these changes in posture. The presence of a tricuspid murmur can thus, in the majority of cases, be readily determined. In judging of the right heart the power to determine with accuracy the presence or absence of this murmur is essential, as it gives important evidence as to the condition of the right heart.

Let me impress upon you the points I have endeavoured to expound to you. They are: (1) That pulsation in the second, third, fourth, and fifth spaces, half an inch or more within a vertical line drawn through the apex, is caused by the right ventricle; and (2) that you have to differentiate tricuspid from mitral murmur on the lines I have formulated for you.

ABNORMAL PHENOMENA.

Visible Pulsation of Right Ventricle.

From these elementary points, which it has been necessary to dwell upon owing to the prevalence of misconceptions, we pass to the consideration of their bearing on the investigation of the condition of the heart. In the dorsal decubitus and in normal conditions the pulsation of the right ventricle is not visible save in persons with exceptionally small and thin chests. Visible pulsation means either that the right ventricle is dilated or that the left heart is dilated and has lifted the right ventricle into closer contact with the chest wall. With regard to the first of these explanations, I would warn you against a too facile belief in dilatation of the right ventricle; as a matter of fact, although various interesting changes occur in the right ventricle, dilatation such as is common in the left ventricle does not occur, for the simple reason that a very strong muscular band passes from wall to wall preventing it. The *conus arteriosus* readily dilates, and when it does so it carries the origin of the pulmonary artery outwards and upwards. With regard to the second explanation, it has this important practical significance, that visible pulsation of the right ventricle may be proof of dilatation of the left heart, and herein, perhaps, lies its chief value as a clinical sign.

Accentuation of the Pulmonary Second Sound.

Returning to the auscultation of the right heart, you only require to be reminded that the second sound produced by the closure of the pulmonary cusps may be accentuated in its own area. The accentuation means heightened pressure in the pulmonary artery, and, when primary lung changes are excluded, it means increased fullness, with the consequent degree of increased difficulty, in the pulmonary circuit. Accentuated pulmonary second sound thus indicates the measure of impairment of the left ventricle which has determined the increased difficulty in the pulmonary circuit. Whenever the left ventricle is overstrained some degree of dilatation occurs. This necessarily means an increase of residual blood in the ventricle, a corresponding measure of greater distension of

the left auricle, and the increased engorgement of the pulmonary vessels which leads to the accentuated pulmonary second sound. You have here, then, a second means provided by the right heart of helping your judgement as to the state of the left heart.

Systolic Murmur in Pulmonary Artery.

The presence of a systolic murmur in the second left intercostal space close to the sternum and strictly limited to this area is frequently noted. The conditions in which the murmur is present shall be presently dealt with; meanwhile I ask you to note that the murmur is heard over the first part of the pulmonary artery; that this is the position of this part of the artery is confirmed not only by observations made after death, but also by the fact that, either by palpation or auscultation, or by both, the vibrations caused by the closure of the pulmonary cusps or the localized intensity of the sound enables us to locate with absolute precision the exact point where the artery joins the conus arteriosus. An interesting and important characteristic of the murmur is that during inspiration, especially during a somewhat deep inspiration, the murmur disappears to reappear during expiration.

As to the conditions in which this murmur is present, chlorosis may be taken as an example. In chlorosis three murmurs may be present over the precordia—namely, a mitral systolic, a tricuspid systolic, and a pulmonary systolic. The mode of differentiating tricuspid from mitral and from aortic systolic murmur has been already dealt with. That these murmurs are not due primarily to the impoverishment of the corpuscles in haemoglobin is proved by the fact that the murmurs are pronounced in a case of chlorosis if the patient, usually a young woman, has been struggling to carry on her ordinary working duties in spite of an increasing sense of physical weakness. When such a patient comes into hospital and is kept in bed, two of the three murmurs commonly disappear in a few days, long before any material improvement has been effected in the blood. The mitral and tricuspid murmurs are due to dilatation and to such myocardial weakness as allows of leakage at both these orifices during systole. In other conditions of debility these murmurs may also be present. Apart, however, from the presence of mitral and tricuspid murmur, the systolic murmur in the pulmonary artery is frequently present as the only murmur heard over the precordia, and it is this murmur I specially want to explain the significance of and to show you that its presence enables us to judge of the condition of the left heart. The explanation I offer to you of the mode of production of this murmur is as follows: We have already seen that the right ventricle is lifted by dilatation of the left heart into close contact with the chest wall, so that its pulsations may be visible in the third, fourth, and fifth left spaces; systole of the right ventricle, especially systole of that portion of it called the conus arteriosus, carries the origin of the pulmonary artery obliquely downwards and to the right; if you endeavour to simulate this action, you will find that the anterior and posterior surfaces of the artery at its origin are approximated, and that a relative narrowing is thereby produced. This narrowing is, to my mind, undoubtedly the mechanism by which the murmur is produced. It explains the disappearance of the murmur during inspiration, for with inspiration the heart has a freer forward movement and the kink is prevented. This explanation gives an important value, and I believe the true value, to this murmur. Its presence becomes a proof of a dilated left heart with usually an enfeebled myocardium. It is present in anaemia, in febrile conditions, in debility, and as a result of heart strain. It belongs to the class of murmurs which are called *functional* to differentiate them from murmurs due to endocarditis and called *organic*. The murmur is present in cases of organic mitral lesion when the origin of the pulmonary artery has not been carried to the left and upwards by the dilatation of the conus arteriosus.

Pulmonary Diastolic Murmur.

Pulmonary diastolic murmur not due to endocarditis at this orifice is, in my experience, very rare. I have, however, recently seen a case of the kind. The patient was a young Royal Field Artillery officer who had returned to light work after recovering from an extremely feeble

heart following upon a febrile attack in Flanders. The light work had proved too much for him, and he showed a faint diastolic murmur over the pulmonary orifice, a faint systolic, tricuspid murmur, a right auricle considerably to the right of its normal position, and a marked ventricular systolic wave in the neck veins. This was a case of pure strain in a heart that had materially improved in myocardial strength but not sufficiently to withstand the strain of the work laid upon it. The murmurs disappeared under physical rest and medicinal treatment.

Explanations.

The explanations already given of the phenomena with which we have dealt may be supplemented with advantage. In the first place, feebleness or absence of the first sound over the right ventricle means weakness of the myocardium of that chamber, and in stout people it commonly means fatty infiltration. Cases of this kind die suddenly from some sudden physical effort, death resulting from right heart failure, not left failure. As we have seen, accentuation of the pulmonary second sound, systolic pulmonary murmur, systolic tricuspid murmur, diastolic pulmonary murmur are the auscultatory phenomena, having origin on the right side of the heart, which may be present. They all indicate strain, varying in degree, of course—strain in the sense that the myocardium is being called upon, or has been called upon, to do more than it can do comfortably or satisfactorily. Such strain leads to dilatation, sometimes of the left heart, at other times of the right, sometimes of both. Some of the phenomena produced on the right side of the heart become the index and guide to strain of the left heart; these are especially accentuation of the pulmonary second sound, pulmonary systolic murmur, and pulmonary diastolic murmur. The presence of tricuspid murmur shows, of course, that the right ventricle is dilated, or atonic and enfeebled, either from initial strain or from the strain due to heightening of the pulmonary blood pressure the consequence of initial strain of the left ventricle. The auscultatory phenomena result from relaxation and dilatation, and it is that fact which gives them their clinical significance and importance. Visible pulsation of the right ventricle has the significance already dwelt upon, and it is sometimes more valuable as an index of left-sided than of right-sided dilatation.

Venous Pulsation.

I now ask your attention to a further source of information—to another set of phenomena from which important deductions can be made and which may lead very promptly to accurate diagnosis. I mean pulsation in the veins of the neck. There are two methods of making observations on these: the first is by means of the unaided eye. Fullness and pulsations, the rhythm of pulsations as timed by cardiac systole, whether they are entirely synchronous with systole, or what their time relation to systole may be, can be seen and noted, and let me impress upon you that this field of observation ought to be diligently explored by you. The second method of investigation is by means of that beautiful clinical instrument invented by Sir James Mackenzie, and known as Mackenzie's polygraph. The latter method gives details which the eye cannot provide; at the same time I repeat that the unaided eye carries us a long way.

Pulsations in the veins of the neck are of course determined by the right side of the heart. This simple proposition is fundamental, and when it is fully grasped the second step is inevitable—namely, that such pulsations can only be caused by contraction of the ventricle or of the auricle. Pulsations are therefore systolic in time when ventricular in origin; all other pulsations are diastolic in time, and have their origin in the auricle. In the consideration of this aspect of our subject I confine myself to cases which are at present under observation, and I shall show you on the screen tracings made by means of the electro-cardiograph and by means of Mackenzie's polygraph.

CASE I.—R., a woman aged 65, had a pulse-rate of 40 when I first saw her. The pulse-rate corresponded with the number of ventricular systoles. On inspection of the veins in the neck there was visible a wave synchronous with ventricular systole, and between each of these another wave, which was presumably auricular systolic

in time, and it was so regular that there was little doubt that the case presented the phenomena of a 2 to 1 heart-block. I show you the polygraph tracing (Fig. 1) in which

Fig. 1.—Case I. Polygraph tracing, 2 to 1 heart-block.

each wave marked *a* is produced by the auricle which is contracting quite rhythmically; the wave *c* is the communicated wave produced in the carotid artery. A few

Fig. 2.—Case I. Electro-cardiogram, 2 to 1 heart-block.

days later the electro-cardiogram (Fig. 2) was taken, and you note that each wave *r* which is near the commencement of the ventricular movement is preceded by two auricular contractions marked *p*. The diagnosis of a

Fig. 3.—Case I. Alternate ventricular systoles preceded by two auricular systoles.

2 to 1 heart-block was thus confirmed. This patient's heart was improving, and even at the same *séance* as gave us Fig. 2, Fig. 3 was also obtained, and shows that only every alternate auricular systole *p* was not followed by the ventricular wave *r*.

CASE II.—W., a man aged 60, with marked cardiac irregularity, showed in the neck to the unaided eye a confused succession of undulatory movements, in addition to the respiratory distensions and emptyings. The polygraph tracing from the neck and the radial artery (Fig. 4) gives the position of the communicated carotid pulse

Fig. 4.—Case II. Polygraph tracing.

marked *c*, and you note there is an absence of the auricular wave present in the preceding tracings. In fact, there is no evidence here of rhythmic auricular systoles; there is practically what used to be called

paralysis of the auricle, but is now known as auricular fibrillation. The electro-cardiogram (Fig. 5) bears out the diagnosis of extreme irregularity, the absence of a true

Fig. 5.—Case II. Electro-cardiogram, no auricle wave.

auricular wave, and the opinion that the patient had a fibrillating auricle.

CASE III.—S., a man aged 54, with a systolic mitral murmur and a large heart, showed a ventricular systolic venous wave in the neck. The tracing (Fig. 6) shows the position of waves *a* and *c* as taken by the polygraph.

Fig. 6.—Case III. Polygraph tracing, in which the venous pulse seemed to be systolic.

The timing of visible venous pulsations is sometimes difficult, but in many cases ventricular systolic and auricular systolic waves can be separated, and their presence must be a measure of the fullness of the right side, especially of the right auricle.

I do not follow our subject further to-day, but you will understand that the study of the means by which the right side of the heart can be investigated, and the method of interpretation of the phenomena which I have presented to you, are able to guide you to a true estimate of many a heart that will come under the consideration of some of you, probably in the near future. The matters I have dealt with lie at the foundation of a true understanding of overtaxed hearts.

THE THEORY OF BLOOD PRESSURE MEASUREMENT

WITH SPECIAL REFERENCE TO THE USE OF SCHEMATA AND BLOOD PRESSURE INSTRUMENTS, TOGETHER WITH AN EXPLANATION OF THE DISCORDANT RESULTS ARISING FROM THE APPLICATION OF THESE INSTRUMENTS.

BY

LEONARD HILL, F.R.S.,

DIRECTOR, DEPARTMENT OF APPLIED PHYSIOLOGY, VERTICAL RESEARCH COMMITTEE.

AND

JAMES M. McQUEEN, CAPTAIN R.A.M.C.(T).

RESEARCH FELLOW OF ABERDEEN UNIVERSITY.

THE study of blood pressure measurement has been of slow growth. The literature of the subject in past years shows how varying types of measuring instruments were employed, how the readings of systolic pressure obtained by them differed with the type of instrument; how with the same instrument discordant readings were obtained from arteries in different situations, where equality or something approaching to equality of reading might have been expected.

Much attention has also been given to the fixing of the diastolic standard. Here also disagreements were to be met with, disagreements both on the nature of the auditory and on the nature of the oscillatory index. Recent work, however, has made possible methods of accurately determining both the systolic and the diastolic pressure in the human subject.

Considerable progress, apart from the fixing of standards, has been made in the theory of blood pressure measure-

ment. A wider knowledge of the factors involved now renders capable of explanation many of the difficulties and inconsistencies of blood pressure measurements. Let us consider first the theory involved in the use of schemata in the elucidation of the phenomena of blood pressure measurement. Such schemata aim at the simplification of the factors involved. The schemata used by Erlanger, by MacWilliam and his co-workers consisted of a compression chamber filled with water in which an artery was placed, and through this artery a flow of water was maintained under a pressure made to pulse from diastolic to systolic level. A constant peripheral resistance was arranged to impede the flow from the artery. In the latest schema used by Erlanger the resistance is infinite, and there is no flow.

Now all these schemata simplify the factors involved in blood pressure measurement, but they neglect a highly important factor which Flack, Hill, and McQueen have drawn attention to—namely, the necessity of providing a peripheral resistance which should increase *pari passu* with the increase of the compression pressure, thereby approximating closely to the physical conditions which pertain to the use of the armlet on the human being. By the provision of such a resistance Hill, Flack, and McQueen were able to explain the increase in the amplitude of the pulse tracing (known to clinicians) that is obtained from the radial artery at the wrist when the armlet is made to compress the upper arm with pressures varying from 0—to just below diastolic pressure; they were also able to elucidate the mechanism of production of the *dull* (Korotkoff) sounds which are heard on auscultation of the artery below the armlet. They showed that the pulse-wave passing under the compressing armlet was actually augmented as the compressing pressure rose from 0—to just below diastolic pressure, and this augmented pulse-wave stretched the arterial wall beyond the normal, and so gave rise to those dull tension sounds which are heard when the compression is below the diastolic pressure. Thus, when Erlanger and MacWilliam simplify their schemata and make the peripheral resistance either a constant or an infinite resistance, they appear to us to ignore one of the most essential physical factors involved, and lose thereby a knowledge of an essential part of the phenomenon of the Korotkoff sounds—namely, the mechanism of the production of the dull sounds.

It has been found by Flack, Hill, and McQueen that in their schema, with a properly contrived peripheral resistance, the systolic pressure is accurately measured by that pressure which obliterates pulsation (felt in a piece of artery placed beyond the compression chamber), and that diastolic pressure can be no less accurately measured either by the auditory method (sudden diminution of sound) or the oscillatory method (maximal pulsation). MacWilliam, using his imperfect schema, failed to get agreement between the auditory and oscillatory indices. The compression in all forms of schemata used by the different workers is a fluid one and so equally applied all round the artery placed within the compression chamber. Accordingly the assumption is made that such schemata more or less accurately resemble the conditions of an armlet placed round the upper arm when compression is applied.

One is led to believe that the tissues, muscles, tendons, etc., which lie in relation to the brachial artery transmit the pressure precisely as the fluid round the artery in the compression chamber. However, it was exactly on this point that older writers had their doubts. Tiegerstedt called attention to the possibility of a loss of pressure in transmission through varying integuments. The same idea is still to be noted in Erlanger's recent paper on the mechanism of the oscillatory criteria. Here, then, we must consider these questions: Do the tissues transmit pressure like water? Does a muscle with an elastic membrane surrounding it transmit pressure precisely as water? Or do the muscles, tendons, connective tissue transmit pressure but imperfectly, and are all our measurements more or less approximations?

Let us analyse more closely the factors involved in a circular compression chamber. One may state that the pressure must not merely be delivered equally all round the artery, but, what is equally important, the fluid or air, if air be used, must be capable of being moved with each pulsation—that is, the compressing pressure must be

applied in a vibratory manner, and the periodicity of its vibration must be the periodicity of the pulse.

If the compression pressure be rigidly applied the whole schema fails. This was shown to be the case by Flack, Hill, and McQueen, and was brought out again later when the compression tube was applied to the femoral artery in certain animal experiments carried out by Erlanger. He notes that the Korotkoff sounds always disappear when the closing of the stopcock, which renders his arteriograph more rigid, catches the pulse in the diastolic phase. In other words, a circular compression chamber of a pressure above diastolic, made rigid at the moment of diastole, holds the artery closed during the entire pulse cycle. It is quite obvious that it should do so, because the pulse must simply beat against the walls of an artery compressed and deformed into a flattened shape, while in diastole, and then surrounded by a rigid medium. An artery, if it is to expand during the pulse pressure phase, must expand by virtue of its power to move the whole compressing medium.

Accordingly those who use a schema with compression chamber to determine the phenomena involved in the estimation of systolic and diastolic pressure must use a schema which permits of the compression being applied in such a way that it can yield and be pulsed, or, to use the terminology of Erlanger, the medium in the chamber must have a sufficient amount of "compressibility."

Hill, Flack, and McQueen and Ingram first drew attention to this phenomenon in their study of arteries placed superficially and resting on bone—for example, the *dorsalis pedis*, temporal, or the aberrant radial artery. When the bag of Hill's pocket sphygmometer was placed on an aberrant radial artery at the back of the wrist or on the *dorsalis pedis*, a systolic reading of, say, 40 to 45 mm. of Hg was obtained. The artery was deformed at pressures below diastolic pressure, and as the compressing medium, the bag, was not capable of being transformed into a vibrating or compressible pressure by the beat of the aberrant radial artery alone, or by the *dorsalis pedis* alone, the pulse ceased to pass below the bag. On the other hand, when an armlet was placed over the aberrant radial artery at the back of the wrist so that in addition it embraced the pulsing tissues of the forearm on the front of the wrist, the reading rose to 110 or 115 mm. of mercury, a close approximation to the real systolic pressure. When, on the other hand, the front of the forearm was encased in a wooden groove, and the armlet put on outside this, so that pressure of the armlet could be applied on the aberrant radial artery, but ceased to be under the influence of the pulsing tissues of the front of the forearm, the reading fell to 40 or 45 mm. of Hg, a precisely similar reading to that obtained by Hill's bag.

In the one case the artery is deformed by the compression from the circular into the oval or flattened shape, and the frictional resistance to the passage of the pulse wave is thereby so increased that the pulse spends its force in dilating the elastic wall of the artery *above* the point of compression, and does not pass through. In the other case the veins and capillaries are compressed so that blood cannot be expressed, and the whole mass of blood vessels in the compressed area becomes filled with blood, which pulses, and the artery keeps its circular form, and cannot be deformed until the compression rises above the systolic pressure.

It is obvious that the blood flow is not absolutely stopped at any pressure under systolic. It continues to escape from the veins as the systolic pressure in the mass of compressed tissues overcomes the pressure of the compressing armlet, the capillary channels becoming all filled to distension. The tissues under the armlet become comparable to the brain enclosed in the skull, where, with each arterial pulse, an equivalent venous escape takes place.

The necessity of applying compression so that the whole mass of tissue vibrates with the pulse was first emphasized by Hill, Flack, and McQueen. To use the terminology employed by them, at each beat of the pulse the compressing bag or armlet must be lifted off the artery; the damper must be a vibrating damper if true systolic readings are to be obtained.

When the armlet embraced the aberrant radial artery together with the whole forearm, the pressure in the armlet became a vibrating pressure vibrated by the pulse

which affects the whole mass of tissue in the front of the forearm, all the vessels of which mass are filled with blood. When, on the other hand, an artery lies on bone and is alone compressed by the armlet or Hill's bag, the artery, *per se*, is powerless to lift the armlet or bag at each pulse; the pulse strikes the artery deformed near diastolic pressure and fails to pass through.

The conditions are precisely similar to those produced by Erlanger when he closed the stopcock of his schema during diastole, and at the same time made rigid the rubber membrane of his apparatus. The action of the simultaneous pulse of all the vessels in the mass of tissue compressed by the armlet or bag in pulsing the armlet or bag off the artery, thereby rendering the whole compressing system compressible, Flack, Hill, and McQueen designated by the term "resonance."

It was shown that when a pressure in the armlet was raised by, say, 10 mm. Hg, those veins under the armlet with an internal pressure lower than 10 mm. of Hg were compressed, and the whole capillary area rose to 10 mm. of Hg pressure. So with each increment of pressure in the armlet an equivalent rise of pressure in the capillary system took place, so long as the systolic pressure of the artery supplying the capillary area was not overtopped and the artery shut up. Consequently the pressure that an armlet exerts on the mass of tissues is obtained through the compression of the veins, and the mass of blood congesting in the tissues through the compression of the veins transmits the pressure to the artery. Here one has the counterpart of the fluid in the schema, and the pulsing beat of the mass lifts the armlet off the artery precisely as the mass of fluid surrounding the artery in a schema, constructed of suitable resilience, is lifted by each beat of the artery. In the case of the schema the artery by its pulse moving the arterial walls transmits their vibration to the compressing mass of fluid. In the case of the armlet the pulse in the main artery passes into all the arterics and arterioles of the mass of tissue embraced by the armlet, and it requires the sum of all these arterial pulsations to vibrate the armlet, or, to use the terminology of Erlanger, to render the armlet "compressible." The experimenter arranges his schema so that the artery enclosed is fully capable of moving the compressing mass around it. But when an armlet is used, it is found that the main artery alone is insufficient, and that the throb of the whole mass of tissue enclosed is required.

There is one essential condition to be complied with before a blood pressure instrument can measure accurately. It is obvious that it must be broad enough to compress a sufficiently large area of veins, and so embrace a sufficiently large enough pulsing area around the artery.

The first blood pressure instrument devised by Herissart conformed to that requirement. The bag or capsule as pictured by him was broad. Succeeding inventors, endeavouring to improve the instrument in portability or neatness, diminished the size of the bag, with resulting inaccuracy.

When a small bag is applied to an artery it closes the veins underneath it; but owing to the multiplicity of lateral connexions in the vascular system, the veins and capillary system pressed on are obliterated, through the blood escaping by these collateral channels. Similarly, the physician who places his finger on the radial artery (with, say, a systolic pressure of 130 mm. of Hg in it) deforms the artery at a pressure of, perhaps, no more than 40 mm. of Hg, and if the systolic pressure were 200 mm. of Hg, his finger would deform the artery at 70 mm. of Hg or so, depending not on the height of systolic pressure but on that of the diastolic pressure. Consequently, his estimation of changes in blood pressure in an artery is only relative; the range through which he appreciates rises of pressure is limited, and his reading of change of systolic level really depends on whether the diastolic pressure is raised correspondingly to the rise of systolic pressure. The finger of the physician easily deforms the artery into the oval or flattened shape, and so prevents the pulse from passing, because the area of veins compressed by the finger is totally inadequate. There is no mass of pulsing tissue under the finger, and the finger becomes a rigid damper.

In a blood pressure measuring instrument, then, the area of the compressing bag or armlet must be adequately broad to compress sufficient veins, so that the blood is congested

under the bag or armlet and the pulsation of the mass of tissue is secured.

Instruments such as Oliver's haemodynamometer, with a small pad placed on an artery from which systolic and diastolic pressures are obtained by an oscillatory index, fail because the pad is not broad enough. They deform the artery, as the finger does. The bag of Hill's pocket sphygmometer, on the other hand, is made large enough to compress the whole of the forearm; the hand enclosing the bag compresses the back of the wrist. Here we have the explanation of many of the discordant readings in the literature of blood pressure measurement. The instruments varied in the breadth of the area which compressed the veins.

There remains to be considered the discordant readings obtained with the same instrument on different sites. It was pointed out by Tiegerstedt that readings of the systolic pressure in the temporal artery varied greatly from those of the radial artery taken with the same instrument. Loss of pressure due to the covering tissues in the case of the radial artery was called in to explain the discrepancy. That false idea—of an obstruction which the tissues place in the way of accuracy in blood pressure measurement—runs through most of the literature and still persists. Now when the instrument was applied to the temporal artery, where it lay exposed on bone, the reading was certain to be erroneous and too low. In fact, the reading would be exactly comparable to the aberrant radial artery or dorsalis pedis. Here we have no mass of tissue surrounding the artery, where with the simultaneous compression of the veins a pulsing mass could be developed around the artery. Consequently, if the instrument used were broad the readings from the radial and from the temporal artery must differ. But where the instrument had a narrow bag or pad, the readings of the radial artery and the temporal artery would approximate, and both would be equally erroneous. Because with a narrow pad or bag the tissues surrounding the radial artery, though there to be utilized, could not be brought into play.

Consequently, readings become accurate, not because pressure can get at an artery without loss through tissues, but because when sufficient tissues, and these amply supplied with blood, are embraced under the compressing pressure, the pulse of the congested tissues enables the compressing pressure to be a resilient pressure and not a rigid pressure, and prevents continuous deformation of the artery until the systolic pressure is overtopped. Flack, Hill, and McQueen showed that when all the vessels of the forearm are dilated by heat, while those of the upper arm are constricted by an ice-bag, then the artery in the upper arm is obliterated by a lower armlet pressure than it is in the forearm. They thus demonstrated the importance of the blood in the tissues by a conclusive experiment.

When one turns to the consideration of auscultatory indices, the same laws apply. Using Hill's bag on the aberrant radial artery (where it lay on bone) sounds were heard, but not sounds similar to Korotkoff's sounds. The level of pressure and the range of pressure at which sounds occur were all erroneous. The diastolic index was absurdly low and the systolic index was 40 or 45 mm. of Hg, because the artery was deformed and held deformed by the rigid pressure. When the armlet was applied to the aberrant radial and the front of the forearm was enclosed in the wooden groove so that the armlet did not come under the influence of the pulsing tissues, the Korotkoff readings were exactly the same as with Hill's bag and wrong.

When the armlet was made to embrace the forearm—that is, the mass pulsing tissues—the readings in the aberrant radial rectified themselves.

Consequently, when Erlanger writes, "Views assigning prime significance to the tissues surrounding the artery are invalidated by the fact that the bare artery suffices for the production of characteristic sounds," his argument is fallacious. The bare artery under the armlet or under Hill's bag neither gives the characteristic Korotkoff's sounds nor does it suffice to indicate systolic and diastolic pressure. It produces sounds the whole range of which appear below diastolic pressure.

The sounds which Erlanger succeeded in hearing in the isolated artery he obtained by compressing the artery

circularly with fluid, and after carefully arranging that the size of the arteriograph and its compressibility were such that it was within the power of the artery to pulse the whole compressing mass of its walls.

Erlanger does not seem to realize that what makes the armlet on the upper arm as "compressible" as his arteriograph is not the beat of the brachial artery alone, but the simultaneous throb of the whole mass of tissues below the armlet.

Further, the genesis of Korotkoff's sounds owe their fundamental origin to this mechanism brought into play by the compression of the surrounding tissues. Erlanger states: "Hill, Flack, and McQueen maintain, *without offering any experimental evidence for their view*, that the compressing armlet converts the compressed area of the arm into a resonating mass; the pulse is not damped down in the labile arterios, but strikes the blood, which fills to distension, not only the main artery, but every patent arteriole throughout the mass, and causes the whole, tense mass to vibrate."

It is difficult to believe that Erlanger has followed the series of researches of Hill, Flack, and McQueen. In their work they show how the veins are compressed and the peripheral resistance rises as compression of the armlet rises; how this rise in pressure stretches the arterial wall and produces the dull sounds; how the blood is congested in the mass of tissues under the armlet. Consequently, through this action of the armlet on the tissues, both under it and beyond it, each pulse strikes the blood, and the arterial wall experiences an additional strain as the kinetic energy of the flow of blood meets the obstacle of contained blood in front of it. Erlanger describes this phenomenon as water hammer, but the use of this term brings out no new idea to that already demonstrated by Hill, Flack, and McQueen.

We conclude, then, that—

1. To give accurate information on the factors concerned in blood pressure measurement, a schema must permit of compression being applied to an artery in a pulsable and not rigid manner, and a rise of peripheral resistance *pari passu* with increasing compression must be arranged for.

2. When an armlet or bag of Hill's pocket sphygmometer is made to compress an artery where it lies on bone with little tissue round it—for example, temporal, dorsalis pedis, aberrant radial—it deforms the artery and prevents the passage of the pulse at a pressure less than diastolic. The finger of the physician acts in the same way, and therefore cannot estimate the systolic pressure accurately.

3. Compression of the tissues surrounding the artery so as to block the venous outlets is essential to accurate blood pressure measurement. This congests the blood beneath and beyond the armlet or bag. The pulsing of the congested mass of tissues renders armlet or bag capable of delivering a circular compression to the artery, and one which yields to the pulse and prevents deformation of the artery until the systolic pressure is overtopped.

4. Sufficient area of veins must be blocked if the blood pressure instrument is to be an accurate one, consequently the bag or armlet must be broad. The bag, together with the observer's hand, enclose the forearm, and so makes the bag of Hill's pocket instrument equivalent to the armlet. Failure to make the bag broad accounts for many inconsistencies in the literature of blood pressure measurement.

FOR some years rabies had decreased in France almost to vanishing point. Owing to the large number of dogs which since the war have taken to a wandering life and thus escape police control, there has been a considerable recrudescence of the disease in many departments. The number of persons bitten by dogs suspected of rabies and treated at the Paris Pasteur Institute was 373 in 1914 and 654 in 1915. In 1916, from January 1st to May 13th, it was 420; this figure, if the same rate of progression is maintained, will give a total of more than 800 for the whole year. On June 9th the Paris prefect of police issued an order that in the streets all dogs must be led in a leash or muzzled and have a collar bearing the name and address of their owner.

THE SYSTOLIC PRESSURE IN ACUTE NEPHRITIS.

By RODOLPH G. ABERCROMBIE, M.D.,
TEMPORARY CAPTAIN R.A.M.C.

I HAVE recently treated at a base hospital in France several hundred cases of nephritis occurring amongst the soldiers of the Expeditionary Force, and have taken advantage of the opportunity thus afforded for the study of the blood pressure during the acute phase of this disease.

The characters of war nephritis have already been described;¹ here it may be said that it presents the usual features of an acute nephritis of moderate severity, and that, as in other forms of acute nephritis, the blood pressure appears to be always raised at some period during the course of the disease.

Duration of Elevation of Pressure.

In cases of average severity the pressure was usually raised for a period of from five to ten days after the patient's admission to hospital; not infrequently, however, the elevation persisted for several weeks, so that the patients were transferred to England with the pressure still high.

Range of Systolic Pressure.

During the early stages the systolic pressure usually ranged between 135 and 180 mm. Hg; exceptionally, and particularly in association with convulsions, it reached 200 or 210. The pressure was thus lower than that usually seen in chronic nephritis; indeed, a pressure of over 200 was found to be presumptive evidence that the disease was really of long standing.

Diurnal Variations in Pressure.

A striking feature was the wide diurnal variation which often occurred between the morning and evening blood pressures. Just as in certain diseases there is a wide difference between the morning and evening temperatures, so in this form of nephritis some agent appears to be at work which causes an evening rise of blood pressure and a morning fall; the difference between the morning and evening pressures may be 20, 30, or even as much as 60 mm. Hg (Chart 1 and Chart 2).

All the charts here reproduced show the systolic pressure taken twice daily, namely at 10 a.m. and 6 p.m., and recorded in millimetres of mercury. The palpatory method was used, with the patient recumbent; a tambour sphygmomanometer (Tycoos) was employed.

If Charts 1, 2, 3, and 4 be examined, it will be noticed that had the morning blood pressure alone been recorded, a totally erroneous idea of the course of the pressure would have been obtained; indeed the chart would have been as misleading as the temperature chart of a case of tuberculosis upon which only the morning temperatures were shown.

When the blood pressure was falling from day to day, it usually did so in a series of morning remissions and evening rises, thus forming a descending "staircase"

CHART 1.—Systolic pressure, taken twice daily at 10 a.m. and 6 p.m., and recorded in millimetres of mercury. "Staircase" descent.

(Chart 1). Exceptionally, when the pressure fell unusually rapidly, the evening pressure was lower than that

CHART 2.—Systolic pressure, taken twice daily at 10 a.m. and 6 p.m., and recorded in millimetres of mercury.

recorded on the preceding morning (Chart 3); such a chart may be compared to that of a case of pneumonia terminating by crisis.

CHART 3.—Systolic pressure, taken twice daily at 10 a.m. and 6 p.m., and recorded in millimetres of mercury. Termination by crisis.

A frequent type of record is shown on Chart 4. During the early phase of the disease the pressure rises and falls irregularly; a stage is then reached of morning remissions

CHART 4.—Systolic pressure, taken twice daily at 10 a.m. and 6 p.m., and recorded in millimetres of mercury.

and evening rises forming a descending "staircase"; subsequently the pressure becomes subnormal, rising later to the normal.

Association with other Symptoms.

In association with uraemic convulsions (14 cases) the pressure was found to be always raised, but to a variable extent; in some cases it was 200, in others considerably lower; in one severe case the systolic pressure taken a few hours before the fit was 135. Immediately after the

fit the pressure was often over 200, probably owing to the great muscular exertion.

Two symptoms, usually nocturnal in incidence, appear to be specially associated with the great evening rises of pressure—namely, paroxysmal dyspnoea and headache. The connexion between these symptoms and the rise in pressure is undergoing further investigation.

Usually the amount of albumin diminished *pari passu* with the fall in pressure, although residual albuminuria often persisted after the pressure had fallen to the normal. Sometimes, however, the two curves bore no relation to one another. During convalescence transient elevations in the blood pressure occasionally occurred; sometimes they followed an advance of diet, but often they formed a part of a general recrudescence of symptoms for which no cause could be assigned.

The estimation of the blood pressure was found to be of great value both in diagnosis and in judging of the patient's progress. As noticed by Captain W. Langdon Brown,² those patients appear to do well in whom the pressure is at first high and rapidly falls to the normal. Often, however, the morbid process in the kidney appeared to continue after the pressure had fallen to the normal.

Conclusion.

The blood pressure was found to be always raised during some stage of the course of the disease, although not to so great a height as is the case in chronic nephritis. Wide diurnal variations in the pressure were usually present, the pressure being highest in the evenings.

CONGENITAL CYSTIC KIDNEY WITH LOCAL DIFFUSE PERITONITIS: SURGICAL DESTRUCTION OF PART OF KIDNEY: RECOVERY.

By JOHN D. MALCOLM, F.R.C.S. EDIN.,
SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL.

HYDATIDS may develop in the kidney, and a dermoid cyst containing hair has been found in place of that organ in a healthy sheep.¹ Apart from such rare conditions there are two chief forms of cystic kidney. In one an obstruction in some part of the large urinary ducts causes dilatation of the pelvis or calyces by modified urine, pus, or tuberculous matter. Retention cysts thus formed are by far the commonest cystic kidneys. Congenital cystic kidneys are altogether different. In them there is no evidence of obstruction in the renal pelvis or in any lower portion of the urinary tract. The whole renule is transformed into a mass of small cysts, from about half an inch in diameter downwards, with generally a few larger cavities. The walls between are flattened by pressure, so that an irregular honeycomb appearance is presented on section. The cysts usually contain a clear fluid, but in one specimen various cysts contained a transparent fluid, a dark yellowish or brown and viscid substance, and turbid nearly solid material respectively.² Some cysts are dilated tubules, or Malpighian bodies, with their epithelial lining recognizable under the microscope. In other cysts there is no lining epithelium.

One specimen in the College of Surgeons' museum was associated with a similar cystic formation in the liver, and the condition has been found with multiple cysts in the spleen and thyroid. It also occurs with congenital imperfections such as heart malformations, spina bifida, and in anencephalic monsters. Frequently more than one member of a family is affected. These facts suggest, and it is generally believed, that a congenital cystic kidney is an abnormal development. Another view is that the condition is one of new growth, and, again, it has been attributed to an excess of connective tissue causing obstruction in the urinary tubules. It is possible that the pathology is not always the same, and there are cases of single cysts and of a few cysts in the kidney which are not associated with any obvious obstruction of the large ducts. These are generally unilateral, and whether they are modifications of the congenital cysts, or retention cysts,

or new growths is not clear. Congenital cystic kidneys have been found in a pony and in a kitten.³

This abnormal condition may exist without symptoms and the patient may die of some other disease at any time from infancy to old age, the cystic change being discovered at autopsy. All the effects produced are due to pressure on the kidney substance or on adjacent parts.

Obvious enlargement of one or both kidneys or a dragging pain caused by the weight may be the first indication of trouble. The condition is usually bilateral, but more advanced on one side, so that one kidney may distend the abdomen to an enormous size whilst the other, also cystic, is only slightly enlarged. Records show that in these circumstances the small kidney, although cystic, may produce sufficient renal excretion to maintain apparent good health, whilst the larger gives a modified secretion resembling that of a small granular kidney. The specific gravity and urea excretion are reduced, the amount of urine is increased and a small quantity of albumin is found in it.

As the kidney enlarges there is a liability to attacks of pain, sometimes accompanied by fever, during which the mass swells and hardens, shrinking again when the attack ceases. With the pain and fever haemorrhage from the kidney may be associated; this symptom is not obvious in every case, but blood discs in the urine are frequently reported.

Numerous specimens of congenital cystic kidneys are preserved in museums, but it does not appear that individual surgeons have had personal experience of many cases. Two have come under my observation. In the first I acted as assistant to Knowsley Thornton, and the nature of the case, published in 1890,⁴ was not recognized until excision of the kidney was unavoidable. The other kidney was also cystic, but it acted so well that the patient lived five days, although she suffered from intestinal obstruction and underwent a second operation for that condition on the fourth day. It has in recent years been fully proved, by successful nephrectomies, that a small congenital cystic kidney can do all the necessary work. The second patient, whose case is now recorded, gave the following history:

She miscarried, at the age of 31, after two months' gestation, and no renal disease was then detected. Two years later, when eight months pregnant, she suffered from suppression of urine and amblyopia. Labour was induced, and with the first pain the patient had a fit, after which she was unconscious twelve hours. A living child, delivered by forceps, died six hours later. Convalescence was complicated by pain and swelling of the right kidney with fever, but complete recovery took place, except that the kidney remained big, and albuminuria, with increased secretion of urine, was persistent.

At the age of 36 the patient, being then abroad, lost much blood in the urine, and there was again pain and swelling of the right kidney with fever. Operative treatment was recommended but refused on the cabled advice of Dr. F. G. Crookshank, and the symptoms ceased after six weeks. About a year later another pregnancy was terminated at the eighth month by induction of labour, and an apparently healthy child was delivered without trouble in November, 1913, but died after twelve hours. Convalescence was uncomplicated, and good health was enjoyed for another year, although the right kidney was still obviously big, and the secretion of urine copious. During December, 1914, the patient felt ill, and on December 24th, after playing two rounds of golf—a quite usual exertion—she was seized with severe pain in the right kidney, which became big, hard, and tender, and there was blood in the urine. The temperature rose gradually until for three days it was between 102° and 104.8° F.

Dr. Crookshank, who had been in charge of the case, was on war duty, and Dr. S. H. Snell of Christchurch was consulted. He, in association with Dr. Hyla Greeves of Bournemouth, concluded that nothing but surgical treatment could give relief, and I saw the patient, then aged 38, on January 3rd, 1915. The kidney occupied the greater part of the right half of the abdomen, crossing the middle line, and standing out prominently below the ribs. It was so tender that no satisfactory examination could be made, and a slight enlargement of the left kidney was not detected. There was a little albumin in the urine, which had a specific gravity of 1010, but did not contain obvious blood. It was stated that before the attack began the urine was sometimes clear and sometimes thick. A feeble pulse (120), a temperature of 104.8° F., and a drowsy, apathetic brain condition combined to suggest that the patient was dying from absorption of poisonous products. Her friends said that she appeared to be much more seriously ill than on any previous occasion, and it was also stated that the patient's sister died at the age of 38 from the same disease.

This history was obtained from the husband and friends up to the beginning of the last attack on December 24th, 1914. The husband stated that a cystic kidney was diagnosed by Dr.

Crookshank after the first full time pregnancy five years before, and it appeared later that double congenital cystic kidneys were recognized at that time, but nothing that was said suggested the true nature of the disease. A diagnosis of suppurating cystic kidney was made with blocking of the escape of pus. Nephrectomy was considered desirable, but if, as seemed likely, removal of the kidney was impossible, it was thought that relief could be obtained with certainty and safety by draining the kidney.

On January 4th, 1915, the abdomen was opened, and it was then seen that the anterior part of a very long gall bladder was pushed forward well in front of the liver edge and was tightly nipped and indented about its middle, between that edge and the kidney, which was very hard and appeared to be solid. An area extending 4 to 5 inches around the gall bladder showed peritonitis, with adhesions so recent that they were easily separated by a sweep of the finger.

The diagnosis was clearly mistaken, and it appeared that the relief of pressure which seemed necessary could be effected only by removing the whole mass—an obviously dangerous, if not impossible, task. The left kidney was slightly enlarged. To decide whether enucleation could be accomplished the right kidney was exposed by incising the peritoneum covering it, and its whole surface was then seen to be cystic, the cavities being so small that the condition was hardly perceptible to touch. A second examination of the left kidney showed that it was similarly affected.

The nature of the condition was now obvious and an attempt to remove the kidney was considered unjustifiable. But the need for relief was imperative. The kidney was therefore opened through a second incision behind the peritoneum and its structure freely broken up by means of scissors and forceps. The finger alone could not be thrust into the kidney substance, which felt quite solid. No large cavities were opened, and only a small quantity of clear fluid escaped, but the size of the mass was considerably reduced. With the hand in the peritoneal sac as a guide, the region of the renal pelvis was avoided. The upper pole of the kidney, over which the evidence of recent diffuse peritonitis existed, was especially broken up and rendered flaccid. Two large drainage tubes were inserted towards the upper and lower ends of the kidney, and the anterior wound was closed.

The patient was very ill for a few days, and had much trouble from intestinal distension and incontinence of urine. Little discharge escaped and no urine from the drainage tubes, which were kept in nearly three weeks to relieve tension, and after they were quite short to facilitate deep healing. When they were removed the wound soon closed, the kidney being then much smaller than before the operation. The patient's condition gradually improved, and after six weeks she could walk a little, but there was a drag in the right side which prevented her standing upright. Since the operation there has been blood in the urine a few days before, during, and a few days after many menstrual periods, accompanied by pain in the kidney. In July, during a period, the patient lurched heavily from a sudden movement of a train, and then felt a severe stabbing pain in the left kidney for the first time. The left kidney became very big and tender. This attack passed off like the others, and after a time the patient was able to play golf on a putting green.

In November, 1915, after an injudicious attempt to take more exercise, she had a severe attack which did not begin with a period. To the usual symptoms were added vomiting and a rise of temperature. The right kidney was considerably enlarged and very tender, and the patient became so weak and pale that it appeared as if death might occur at any time. After a fortnight the symptoms ceased abruptly, and the conditions rapidly improved. The patient was kept in one room for a time, and became as well as she had ever been since Christmas, 1914. She was able to stand quite erect.

June 6th. Dr. T. Croft Neville informs me that the patient's condition is now very much better than it was six months ago. The right kidney extends below the pelvic brim, but the left is almost of normal size. The patient walks out daily when the weather is warm, but when it is cold she must stay in, and she cannot exert herself much.

This patient was first seen by those responsible for the operation in an acute condition, and the nature of the case was not recognized, but the need for surgical interference was correctly estimated. The failure to recognize the primary disease was due partly to the rareness of the condition, partly to the masking of the indications by the acute symptoms and partly to the diagnosis of cystic kidney, passed on by the husband and accepted in its ordinary meaning. The mistake was a fortunate one for the patient, because with a diagnosis of congenital cystic kidneys the chances of recovery would probably have been considered greater without surgical interference. But the diffuse peritonitis around the gall bladder could not have been recognized without exposure of the parts, and it is practically certain that this inflammation would have spread and proved rapidly fatal. The only useful procedure that might have been advised, if a diagnosis of congenital cystic kidneys had been made, was to reduce tension by emptying some of the cysts with a trocar and cannula from behind the peritoneum. This would have

required innumerable punctures because of the small size of all the cysts, and without inspection of the peritoneal cavity the need for special treatment of the upper part of the kidney could not have been recognized.

Good results seem to have been obtained in reported cases by removing the larger kidney, but it is doubtful whether this is a wise proceeding. Nephrectomy was not practicable in the case now recorded when I saw the patient. Where it is practicable, the effect must be to throw the whole burden of renal excretion upon the second kidney, which is also unhealthy, and which, therefore, will come to an end of its capacity sooner. The disease, after symptoms develop, seems to be inevitably progressive, and relief of tension by an operation which does not destroy more kidney tissue than is necessary would appear to be the ideal treatment if the symptoms indicate surgical interference. The case now recorded shows that diffuse peritonitis is a complication which, though not usually described, is to be feared, and that it may be cured and life may be prolonged by a timely reduction of tension. In this connexion it is interesting to note that the patient's sister is said to have died of the same disease at the same age as the patient when she was operated upon. Another important point shown by this case is the power of healing of a large wound in a congenital cystic kidney.

Medicinal treatment does not come within the scope of this communication, and it is extremely difficult to estimate its influence upon such a rare disease. Iodides seemed to have some beneficial effect, and Dr. Crookshank informs me that thyroid tablets were always useful, but the cystic change made progress in spite of all treatment. Child-bearing would appear to be dangerous whenever renal excretion is deficient, but the symptoms in the case recorded only became marked after the second pregnancy, and there is no evidence that the first and third were harmful. Rest and an invalid life seem beneficial now, but before Christmas, 1914, the patient was very active, playing golf almost daily, and often two rounds, her health being then very good. I am indebted to the above-named gentlemen for permission to publish their names, and especially to Dr. Snell for his management of the case after the operation.

MEMORANDUM ON THE PREVENTION OF AMOEBIC DYSENTERY.

By J. GORDON THOMSON AND D. THOMSON,
CAPTAINS R.A.M.C.

PRELIMINARY REMARKS.

It has been proved that it is of the greatest importance to give a thorough course of emetine treatment to all cases of amoebic dysentery before discharge from hospital. Efficient treatment prevents the patients from becoming cyst carriers. Small doses of emetine, such as 3 or 4 grains given in 1-grain doses daily and then discontinued, must be avoided. Treatment such as this benefits the patients at the time, but it is actually dangerous, as these cases may relapse or become cyst carriers. They also run the grave risk of subsequently developing abscess of the liver. The dose of emetine required to bring about a complete cure varies with the case to be treated. Acute cases treated early may be cured by the continuous administration of emetine up to 7 grains. One grain must be given daily, and on no account should the dosage be intermittent. The giving of 1 or 2 grains and then stopping for a day or two and then continuing is to be avoided. Other cases require 10 grains and more; chronic cases have required 18 to 20 grains. In all cases of cyst carriers experimental evidence tends to prove that administration of emetine ought to be continued till at least 12 grains and sometimes more have been given. Where a microscopic examination of the faeces is impossible, the clinician must use his own judgement, and in all cases he ought to go on with the treatment even after all the symptoms have ceased. It is of the utmost importance to keep the patient in bed during treatment.

When a patient has become a cyst carrier he can as a

rule be rendered non-infective by the administration of emetine combined with magnesium sulphate in doses of 2 drachms every four hours. Here if possible the treatment should again be controlled by the microscope. In most cases 10 grains clear out the cysts of the pathogenic entamoebae, but in one case we still found cysts after the administration of 13½ grains. This is sufficient to show that the result of treatment by emetine should be controlled by daily microscopic examination of the faeces, and it is also advisable to make another examination some time after the treatment has ceased.

We have now proved that flies are capable of ingesting cysts of the pathogenic entamoebae from infective material and depositing these in their faeces on food. The cysts of *Entamoeba histolytica* will persist for a month, and much longer under conditions in which the stool is not allowed to dry too much. It has been shown that the pathogenic cysts in faeces well diluted with fresh drinking water persist for weeks, and this has also been proved in the Central Laboratory. In Egypt, where the faeces are deposited in the open on sand by the native, we have a constant danger to the community from flies, water, and even blown sand. Fresh faeces can be quickly trampled up in the sand, and small particles of highly infective material adhering to the sand grains may be blown long distances.

PREVENTION.

The following recommendations regarding prevention are based on the foregoing facts.

1. Thorough and Rapid Disposal of Faeces.

In an army it is absolutely essential that all faeces should be disposed of in such a way that flies can have no opportunity of alighting and feeding on them for even one second. Hence it is necessary to employ, in the absence of a flush-water system, either fly-proof latrines or metal buckets containing kerosene or some other anti-septic. Kerosene wards off flies, and it is inflammable and assists in the incineration of the faeces later on. No random defaecation must be allowed even some distance from the camp bounds. This is a common occurrence in Alexandria. The sanitary squads should devote their attention not only to their own compounds, but to the neighbouring clear areas used by the native as latrines. This is of great importance, as we have found cysts of the pathogenic entamoebae in samples taken at random from deposits on the seashore. It has been found difficult in many cases, even in our own soldiers' camps, to make men use the latrines. The reason for this is obvious, as often the latrines are very unattractive and in many cases repulsive to men accustomed all their lives to the privacy of a water-closet. In an army such as now exists, in which men of all grades of society are mingled together, more care ought to be taken in the construction of latrines. Partitions of some sort ought to be placed between each bucket and a special man ought to be detached to keep the place absolutely clean. A little expense would obviate these difficulties.

2. Thorough and Rapid Disposal of Horse Dung and Refuse.

Since flies breed in faeces, horse dung, and refuse, these should be cleared away daily and preferably burnt in a powerful incinerator.

3. Separation of Camps from Native Quarters and Horse Lines.

Camps ought to be pitched at a considerable distance (one mile, if possible) from native villages or dwellings, or else it will be necessary to exercise a thorough sanitary control over the latter. This will be found a very difficult matter, since having no sewage system they are littered with highly infective faeces and dung, and flies abound.

Permanent dwelling camps should also be stationed at a considerable distance from horse lines (if possible, 1,000 yards) since horses always attract flies.

4. Careful Guard of all Water Supplies.

Contamination of water supplies by faecal matter and filth must be avoided, since the cysts of the pathogenic amoebae can live in water for a long time.

5. Fly-screening and Destruction of Flies.

All more or less permanent messes, canteens, and cook-houses ought without delay to be thoroughly fly-screened

before the hot weather brings the flies. The doors should close automatically by means of powerful springs. The ideal state of affairs is to have a passage 10 ft. long with a spring door at each end. This passage serves both as the entrance and exit. This system is adopted in the American houses and hospitals all over the Panama Canal zone, and a special gang of carpenters was sent round periodically to examine the condition of the screening and make any necessary repairs. The extra expense has well repaid the authorities by practically stamping out dysentery amongst the white population. As a second line of defence, even in a fly-screened building, all food on the tables ought to be covered with gauze. This is easily done. All flies which gain an entrance to the building should be immediately destroyed.

6. Supply of Sterile Sand for Cleaning Mess Tins.

This is necessary, as the sand about a camp is very liable to be contaminated and infective. Sand is easily sterilized by roasting or boiling it with water. The sterilized material should be kept in a covered boiler or other metal receptacle.

7. Eating and Drinking in Native Quarters.

Uncooked food, such as salads, vegetables, and ices, also unboiled water and milk, are dangers in all native eastern villages or in the filthy quarters of the larger towns. The milk should always be boiled. As vegetables are often manured with human faeces, they should be thoroughly washed and plunged for a few seconds into boiling water before they are eaten.

8. Recommendations with regard to Hospitals.

Cases of amoebic dysentery should be isolated as much as possible in special wards. Fouled clothing and bed sheets should be placed immediately in antiseptic lotion, so as to prevent flies from alighting on them. The hands must be washed after handling such clothing or the patients themselves, and also after handling bedpans. When bedpans are sent to the laboratory, the report paper should not be secured between the bedpan and its lid, because in this way it becomes soiled. Orderlies must be instructed in these matters and thereafter punished for lack of attention to details. Dysenteric wards should be thoroughly fly-screened, as well as the hospital cook-houses and mess-rooms. In addition, flies should be destroyed in all hospitals by every available device.

9. Early Thorough Emetine Treatment.

All cases of suspected dysentery should receive at once 1 grain of emetine daily at the advanced dressing station, field ambulance, hospital ship, or base hospital. This treatment must not be stopped during the transit towards the base until at least 7 grains have been given. It is bad practice to omit one single dose. The 7 grains should be received in seven days.

10. Microscopic Examination of Faeces before Discharge.

The faeces of every case of amoebic dysentery should be examined microscopically after a full course of emetine in order to determine that they are free from cysts. Patients should not be discharged from a field ambulance for duty, or from any hospital, until they are pronounced free. It should be remembered that the mildest cases may become dangerous cyst carriers.

11. Isolation and Thorough Treatment of Cyst Carriers.

All cyst carriers must be sent to hospital to receive a thorough course of emetine combined with salines. They must not be discharged or allowed to join their unit until quite free from cysts.

12. Examination of all Cooks and Mess-room Orderlies.

No soldier should be employed as a cook or mess-room orderly in a camp or hospital until it has been proved by microscopic examination that he is not a cyst carrier. Particular attention should be paid to this matter where those so employed happen to be natives.

13. Larger Sanitary Staff and Equipment.

There can be no doubt that these sanitary measures are necessary in a country like Egypt. If larger sanitary

squads and equipment could be provided, the measures could be thoroughly carried out, and this disease, with others, would rapidly disappear from our army. The extra expense necessary would be repaid almost immediately, and ultimately save an enormous amount of money and life to the State.

THE CAUSATION AND CURE OF CERTAIN FORMS OF LUNACY.

By RUPERT FARRANT, F.R.C.S., CAPTAIN R.A.M.C.,
LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS.

BEFORE going on foreign service for a second year, I wish to publish the following preliminary conclusions and summary of work directed to the causation and cure of lunacy carried on during the last seven years. The work is a continuation of that previously published on the thyroid gland in the elucidation of goitre and exophthalmic goitre.

The work consists of the microscopical examination of sections taken from the pineal, pituitary, thyroid and sexual glands—first, at different ages and periods of life such as puberty, menopause, and childbirth; secondly, the effect induced in these glands by the acute and chronic toxæmias; and thirdly, the changes found in cases of lunacy.

Clinical examinations were carried out of cases exhibiting signs of enlargement and atrophy of these glands and symptoms of excess or diminution of secretion. Similar examinations have been made on all classes of lunacy for the presence of signs and symptoms. Photographs and x-ray examinations have been made to illustrate their occurrence. Mental cases and others have been examined for the presence of toxæmias inducing the alteration in the glands and the consequent induction of symptoms of excess and deficiency. Bacteriological examinations have been made of the faeces of lunatics and the colons examined *post mortem*.

From some 3,000 sections it is found that these glands vary at different ages and periods of life; with advance of life they tend to atrophy.

It is found that the pineal reacts to certain toxæmias, the ultimate result of which is fibrosis. The pituitary reacts in a similar manner, the terminal result of which is fibrosis; intermediate stages of hyperactivity are seen, and the formation of cysts and adenomata. The reaction of the thyroid to certain toxæmias with the induction of hypertrophy, cysts, and adenomata, I have already described in my lectures as Hunterian Professor in 1915. A comparison was made of such specimens with those obtained from cases of lunacy, apart from those in which a definite pathology has already been proved, such as general paralysis of the insane (other syphilis cases), meningitis, head injuries, etc. The effect of age and of the lethal toxæmias was discounted and the state of the glands in cases of lunacy determined.

In primary and secondary amentia atrophy of the pineal, pituitary, and thyroid were found in three main groups of cases. In dementia præcox an alteration was found in the glands which varied with the duration of the case. Alteration and degeneration was also found in other cases of dementia. In some cases of acute confusional mania, melancholia, manic-depressive and other forms of insanity, changes were found in the thyroid, pituitary, and sexual glands. The changes varied from hypertrophy to atrophy.

Clinical examinations were made of some 1,000 cases of insanity, analogous to those from which the pathological sections had been prepared, for signs of enlargement or atrophy, and the presence of excess or deficiency of secretion from these glands.

The thyroid gland was frequently found to be abnormal in children, adolescent and adult lunatics; its size varied from considerable enlargement to complete atrophy, and the general condition from one of hyperthyroidism and exophthalmic goitre to myxoedema and cretinism.

The pituitary gland was found sometimes to have given rise to symptoms of hyperpituitarism to apituitarism, in idiocy, dementia præcox, and other forms of insanity. Enlargement and atrophy of the pituitary were deduced

from x-ray photographs of the sella turcica and clinoid processes.

Signs of alteration in the pineal were found, especially in children and adolescents, with consequent symptoms of hyperpinealism and apinealism.

Alteration was found in the sizes of the testicles associated with ductless gland changes. Testicular atrophy was well seen in cases of apituitarism. From the histories of cases it was deduced that the stimulation of the sexual organs or its sudden cessation was associated with altered mentality varying from mania to exhaustion psychosis; altered mentality was also found in cases of double castration. Hypertrophy of the prostate was often found to be associated with altered mentality, and after complete removal cases were frequently associated with depression or melancholia.

Some 200 cases were examined for obvious signs of chronic toxæmia. Pyorrhoea and carious teeth were found to be a frequent accompaniment of lunacy in adults; in certain cases signs of chronic intestinal stasis and toxæmia were well marked.

Bacteriological examination of the faeces was made in some 100 cases for simple aerobic infections (apart from cases of *asylum dysentery*). Streptococci were found up to 100 per cent., and *Bacillus coli* was totally absent in some cases of mania. Streptococci were also found from vaginal swabs of puerperal mania.

Colons have been examined *post mortem*, and found to exhibit changes varying from normal to pericolicitis, fibrous thickening of the walls of the gut, and atrophy of the mucous membrane, and in other cases dysenteric ulceration.

It is deduced that many cases of lunacy may be classified according to the toxæmia present and the change that it has induced in the ductless glands.

The effect of the toxæmia varies with the intensity, duration, and the age of the patient; the first effect is stimulation, the final fibrosis. In the fetus and in childhood an acute or chronic toxæmia may induce atrophy of a ductless gland, and consequent maldevelopment and idiocy. Three groups stand out when the pituitary, pineal, or thyroid is atrophied. Cases of dementia præcox exhibit a polyglandular syndrome, and different gland types are to be found, and the appearance of the cases varies whether the gland is hypertrophic or atrophic.

In adults certain toxæmias react on these glands, especially the thyroid and pituitary, and induce stimulation, hypertrophy, and, finally, atrophy. The alteration in the amount of secretion—whether excess, deficiency, or absence—induces an altered mental state, and this, combined with the effect of the toxæmia, renders the patient insane or liable to insanity from slight mental stress.

Alteration in the sexual glands, whether primary or secondary, leads to altered mentality up to insanity.

The lines on which beneficial treatment may be carried out based on the above pathology become obvious; the matter may be summed up by saying that toxæmias, if present, should be removed by medicinal or surgical measures, and the glands allowed to involute if they are hypertrophied, or, if they are degenerated with deficient secretions, these secretions should be supplied. Good results may be expected before cortical brain lesions have taken place.

Careful experimental treatment with control cases is at present being carried out for me at Bethlem Royal Hospital by Dr. Phillips, commencing with the simpler medicinal treatment.

In a work of this nature due credit must be given to those who have so kindly given me pathological material and access to clinical cases. Full acknowledgment will be made when the work is published in detail. Dr. Braxton Hicks has supervised the collection of pathological material during the last year.

M. ÉTIENNE LAMY, perpetual secretary of the Académie Française, has given £20,000 to that body for the foundation of a prize to be applied for the benefit of large families in need of assistance.

JEFFERSON MEDICAL COLLEGE, Philadelphia, was founded in 1826. It has been a chartered university since 1838 and has graduated 13,278 doctors of medicine, of whom 4,678 are in active practice. Efforts are now being made to secure an additional sum of £400,000 for its permanent endowment.

THE TREATMENT OF BACKWARD DISPLACEMENTS OF THE UTERUS.*

BY

FREDERICK J. McCANN, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN, LONDON.

Introduction.

DISCIPLES of the healing art are not infrequently taunted by the laity because their treatment of common ailments is far from satisfactory.

That this is true to a certain extent cannot be gainsaid, for what is of common and everyday occurrence seems not to stimulate the ardour of the scientific investigator, who looks further afield to discover amidst the rarer morbid processes some fruitful source of inquiry. There is a tendency, too, in clinical work, to spend more time and thought over what are termed "interesting cases," and to treat common ailments on a routine plan. Yet such ailments are all-important to the patients, the more so because of their frequent occurrence.

Backward displacement of the uterus is a common ailment which, from its frequency and importance, demands the closest investigation and study in order to decide what measures of relief may be afforded to the unfortunate sufferer.

Happily the treatment has markedly improved in recent years, owing largely to the advances made in gynaecological surgery and to a better understanding of the causation and sequelae, so that women can now be promised a restoration to health which was not attainable in former years.

When a backward displacement is discovered, it is necessary to determine the cause, for this often affords important guidance to correct treatment.

Congenital Displacement.

The displacement may be congenital, for it has been discovered in the newly born.

I have found undersized retroflexed uteri not infrequently amongst Polish Jewesses of the hospital class, who seek treatment for sterility, and in whom there were no symptoms pointing to any uterine trouble. The association of under-development of the uterus, anteversion, dysmenorrhoea, and sterility is well known, but I have rarely found small-sized retroflexed uteri amongst British women. Such examples represent the true congenital backward displacement, and, although fully developed uteri displaced backwards may be found in young girls, it is more than probable that the displacement is acquired. In another type met with in the newly born the cervix is much elongated, the uterine body small, and the organ is retroverted; and in yet another type the uterus is retroverted and anteverted. Needless to say, unless symptoms result no treatment is indicated.

Excessive Uterine Mobility.

Again, excessive mobility of the uterus may be encountered, so that it may at one examination be found displaced backwards and at another occupying an anterior position.

Traumatic Displacement.

The part played by traumatism in the production of backward displacement has been variously estimated from time to time, but from a close study of this subject I have come to the conclusion that in the causation of backward displacements in virgins and nulliparae, and in parous women too, the possibility of traumatism as an etiological factor must constantly be borne in mind.

I have seen backward displacement of the uterus result from accidents in the hunting field, falls on the buttocks, strenuous exercises at school, and recently after strenuous "war work." When the extreme mobility of the normal uterus is remembered it is indeed surprising that this accident does not happen more frequently. Yet it is stated to be very rare, and has even escaped mention by many writers.

The acute displacement is an example of a true intra-peritoneal hernia in which the body of the uterus becomes incarcerated in the pouch of Douglas.

* A paper read before the Harveian Society.

The symptoms suggesting the possibility of an acute traumatic backward displacement may be thus briefly summarized: Pain is referred to the lower sacral region and coccyx. If the woman attempt to stand there is slight nausea and vague distress in the epigastrium. Pain is often localized over the sacro-iliac synchondrosis or down the sciatic nerve. Defaecation may be painful, and headache, generally occipital in type, may be a prominent symptom. Added to these there may be distressing vesical irritability, whilst the menstrual type becomes altered. Uterine haemorrhage may follow the accident or menstruation becomes painful, prolonged, and too frequent. Amenorrhoea has been noted. If treated promptly, there is no change in the menstruation. There is a characteristic posture and gait like traumatic lumbago. The shoulders are stooped forwards, the head carried slightly forwards, the dorsal and lumbar portions of the spinal column being held in a position of slight kyphosis.

The treatment consists in replacing the uterus under anaesthesia, followed by rest in bed for at least a fortnight.

The majority of backward displacements in virgins and nulliparae are, however, encountered in what may be termed the chronic stage.

Treatment of Backward Displacements in Virgins.

When symptoms suggesting some pelvic disorder are met with in a virgin a recto-abdominal examination, preferably under anaesthesia, should be made. If a backward displacement be discovered, it is necessary to determine whether the displacement alone is the cause of the symptoms. A careful abdominal examination should be made to make sure that there is no visceral ptosis (stomach, intestine, or kidney), at the same time noting the condition of the abdominal wall and the general muscular development.

If the woman be of the thin neurotic type, exhibiting various so-called reflex nervous phenomena, pains of various kinds, fatigue after slight exertion, gastric troubles, and constipation with feeble muscular development and visceral ptosis, the uterine trouble is only a small part of her disease, and treatment by pessary or operation would do little good.

For such women local treatment should be avoided, and massage, exercises, fresh air, and appropriate employment will be most helpful. For those in whom the displacement is not associated with visceral ptosis I believe surgical treatment affords the greatest relief.

It is often urged that the woman should be told to forget about her displacement, or if it is not causing marked symptoms it should be left alone, or if discovered accidentally the knowledge should be withheld from her, or, again, she may be told she is neurotic and fanciful, when her sufferings are very real.

Much depends on the attitude the medical attendant adopts when confronted with disorders of this kind. That a backward displacement of the uterus has a profound influence on a woman's health and wellbeing is evident from the extraordinary benefit which follows its cure by operation. And although in my earlier days I approached this subject with a sceptical mind, I am now convinced of the far-reaching effects produced by a backward displacement, and can fully credit the importance given to this subject by our medical forefathers.

Further, it is frequently advised that nothing should be done if symptoms are absent. To this I reply that sooner or later a backward displacement will cause symptoms, and that as a spontaneous cure is not to be expected the sooner the displacement is remedied the better for the patient.

Apart from prevention, the trend of all modern treatment is to apply the remedy in the early stages of disease in order that the malady may be effectually checked. The same principle should therefore be applied in the treatment of backward displacements.

The modern gynaecological surgeon has had the great advantage of being able to inspect the pelvic organs through an abdominal incision, and so obtain a knowledge of living pathology which was denied to his forefathers, who relied solely on clinical or *post-mortem* evidence. From actual inspection on the operating table I have satisfied myself of the frequency with which tubal inflammation accompanies a chronic backward displacement, how the appen-

dages become congested, and adhere to neighbouring bowel or pelvic peritoneum, and how the uterine body becomes enlarged and congested.

It is assumed by some writers that the uterine congestion is due to the body of the uterus being gripped by the peritoneal folds bounding Douglas's pouch. I have paid some attention to this subject by observing the actual conditions when the abdomen was opened. I have seen the uterine body deeply congested, dark purple in colour, on many occasions lying perfectly free from the folds of Douglas, and also uteri whose colour closely resembled the normal being "gripped" by these folds. Moreover, these folds are easily stretched, and the distance between them varies considerably in different individuals, whilst childbearing exerts an important influence.

I believe the uterine congestion is due to the torsion of the broad ligaments tending to retard the venous return, and that where this congestion is only slight in amount the torsion is not so marked, and the circulation better able to accommodate itself to the altered conditions. Needless to say, when the uterus is infected another factor comes into play.

Slow and insidious changes occur in the uterus and appendages which sooner or later will cause symptoms both local and general.

For all these reasons a backward displacement should not be left alone, but should be promptly remedied. In a virgin it is much better to remedy the displacement by an operation than to introduce a pessary. It is surely better for her to have a neat abdominal scar than a torn hymen and a stretched septic vagina.

Treatment of Backward Displacements in Nulliparae.

In the nulliparous married woman the problem is a little different, for should she become pregnant this may lead to the cure of her displacement. Unfortunately, however, although pregnancy may occasionally occur in a uterus displaced backwards, as a rule the displacement hinders conception, and for this reason the woman may present herself for examination.

When an examination is made and a backward displacement is discovered, then the mobility of the uterus should be tested. Can it be replaced into the normal position or is it fixed?

A useful clinical division of backward displacements is into three classes:

1. Those in which the uterus is replaceable without anaesthesia.
2. Those in which the uterus is replaceable with anaesthesia.
3. Those in which the uterus is fixed.

The uterus may be movable to a certain extent without being replaceable in its normal position. Such movement is permitted when the adhesions are not numerous and are filamentous in character. Again, the woman may resent any attempt at moving the uterus, owing to the tenderness of the uterine body or the prolapsed appendages. Such uteri are readily replaced under anaesthesia. If, in addition to tenderness, the adhesions are numerous and strong, the uterus remains fixed even under anaesthesia.

To determine if the uterus be replaceable is the first step in treatment. If replaceable, treatment by pessary may be tried, whilst if the uterus be fixed a pessary will cause pain through pressure on inflamed or sensitive structures.

Method of Replacing the Uterus.

(a) *Bimanual Replacement.*—The uterus may be replaced by the internal fingers pressing the fundus upwards and forwards until it is further assisted by the external hand, the internal fingers being then used to press the cervix backwards and upwards.

(b) *Replacement by the Aid of a Volsella.*—Where there is difficulty in carrying out bimanual replacement the anterior lip of the cervix should be seized with a volsella and the uterus pulled downwards, and then the cervix pushed upwards and backwards, thus causing the fundus to rotate forwards. As a rule, this alone will suffice, but if there be any difficulty, the finger or fingers may be used in addition to push the fundus forwards.

(c) *Replacement by the Uterine Sound.*—The usual method recommended is replacement by means of the uterine sound. With the sound you may infect the uterine

cavity, you may perforate the fundus, or you may produce abortion in a gravid uterus. For all these reasons the sound should be avoided. Nothing can be more reprehensible than the repeated straightening of the uterus by means of the uterine sound, for the risks of infection are very real, and tubal inflammation may follow.

Treatment by Pessary.—Having replaced the uterus, it is maintained in position by a pessary. The capacity of the vagina will have been gauged by the former examination, and a pessary of suitable size should be selected or a cast of the upper portion of the vagina may be taken by means of a thin rubber ring previously immersed in boiling lotion to make it soft, and a pessary of corresponding size can be procured or, if necessary, made. The most suitable variety of pessary is the Hodge or Albert-Smith, made of hard glass or vulcanite. It should be introduced in the antero-posterior diameter of the vulva, the index finger pressing the upper bar backwards and upwards into the posterior fornix. The pessary should be grasped by the vaginal vault, and should not cause pain or discomfort. Before leaving the examination couch the woman should be asked to "bear down," in order to see whether or not the pessary can be pressed out. It is well to request her to report herself in three or four days to ascertain if the pessary is causing any pain or interference with micturition or defaecation. During the wearing of a pessary a daily vaginal douche is necessary, and for this purpose warm saline solution is useful, as it does not interfere with conception. The pessary should be changed every two to three months, when the opportunity may be taken to see if its use may be discontinued or if a smaller or larger size be required.

When asked the question, How long has the pessary to be worn? the answer is, Until the uterus can maintain itself in the normal position. That may be months or years, or it may never maintain itself in the normal position.

Women are often told that they will be cured at the "change of life." This is true when the uterus becomes smaller and the upper portion of the vagina contracts, or when, from an increased deposit of fat, the retentive power of the abdomen is increased. But in parous women with a relaxed vagina and a gaping vulva the condition becomes worse.

I think, therefore, that the prospects of pessary treatment should be put before the patient, and she should be left to decide whether she will endure the inconvenience of wearing a pessary or have surgical treatment.

A vaginal pessary is an unclean thing, requiring constant attention, and as it acts by stretching the vaginal vault it is in reality favouring the condition it is supposed to remedy. As cures by pessary treatment are not numerous, I believe the interests of the patient are best served by advising appropriate surgical treatment. Moreover, the social status is an important factor, for the hard-worked woman has not the time to give the attention and care which treatment by pessary demands.

The uterus may be found tilted slightly backwards in association with a congenital hypertrophic elongation of the cervix, a condition frequently mistaken in practice for uterine prolapse. A supravaginal amputation of the cervix followed by accurate suture cures the condition, and pregnancy has followed this operation. When met with in a virgin the same treatment is employed.

Treatment of Backward Displacement when Pain and Tenderness Exist.

When the body of the uterus is tender and any movement of it is resented, before attempts at replacement are made treatment should be applied. The best is the "ichthyol treatment." For its successful application the patient should rest in bed for a fortnight or three weeks, during which time tampons of glycerine and ichthyol 10 per cent. are inserted into the vagina every other day and a saline douche given once a week, to clear away the excess of ichthyol. Ichthyol vaseline 10 per cent. is rubbed into the flanks, and ichthyol pills 2 to 3 grains given three times daily. It will be found that after this treatment the uterus can be easily replaced and a pessary inserted.

When the uterus is enlarged and there is excessive and irregular menstruation, probably indicating that there is some adenomatous growth *in utero*, the curette should be

employed to remove this growth under anaesthesia, and after all discharge has subsided a pessary may be inserted.

It is here that the operation of curetting may be usefully employed, but only if the menstrual loss is markedly increased, as it is an operation the indications for which are very definitely limited, and it is far too frequently done at the present time.

From a series of cases collected by the late Dr. Herman he estimated that in 40 per cent. menstruation was increased, sometimes in quantity, sometimes in frequency, sometimes in both. Occasionally it is diminished. What is frequently noted is a "relative retention" of the menstrual flow, so that it is prolonged as a brownish discharge for two or three days, and in the intervals between menstruation a uterine discharge, mucoid or muco-purulent, comes away in gushes.

All these symptoms disappear when the uterus is kept in position, and no curetting is required. They prove, however, the evil effects which result from a backward displacement.

The wearing of a pessary is only a part of the treatment of women with backward displacements, and general treatment should always be adopted. For this purpose tonics, exercise in the fresh air, graduated exercises, massage, and dieting are most helpful. The appropriate exercises should be written down and carried out by the masseuse under medical supervision.

The somewhat narrow outlook possessed by many of those who attempt to treat these disorders in women has been the means of diverting countless numbers of patients into the hands of various types of unqualified practitioners. Many patients seem to take a delight in informing medical practitioners that they have tried many doctors without obtaining any benefit, and that they have been cured by massage and exercises. It behoves us all to take the hint, and remember that to strengthen the abdominal muscles and to favour the deposition of fat is the best way of increasing the retentive power of the abdomen.

(To be continued.)

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE INCUBATION PERIOD OF PARATYPHOID B FEVER.

THE following case is of interest as *Bacillus paratyphosus* B was found in the stools some time before the onset of the disease.

The patient, No. 403, Pte. McK., was admitted on September 23rd, 1915, suffering from "dysentery." A specimen of his stools was sent to the laboratory next morning; amoebae were not found. On plating the stool dysentery bacilli were not found, but *Bacillus paratyphosus* B was isolated.

It was thought that the patient might be convalescing from paratyphoid B fever, so a serum reaction was carried out by the microscopic method with negative results.

Twelve days after admission, on October 5th, his temperature began to rise. A blood culture was made on October 7th, and *Bacillus paratyphosus* B was isolated. On October 25th a serum reaction was again carried out, and agglutination of *Bacillus paratyphosus* B was found in a dilution of 1 in 1,000 by the microscopic method.

This case shows that *Bacillus paratyphosus* B can be present in the intestine at least twelve days before the onset of the fever, and that cases which develop in hospital are not necessarily infected in hospital.

FIELD MARSHAL VON MOLTKE, who died suddenly in the Reichstag on June 18th, was a supporter of Christian Science, of which his cousin, the heir of the conqueror of 1870, is the official head in Germany.

THE 4th London General Hospital has added one more to the number of military hospital magazines. Two numbers have appeared, May and June. Its title is *The Fourth*, and it presents a cheerful countenance.

Reports of Societies.

WAR INJURIES OF THE JAWS.

THE annual meeting of the British Dental Association was held in London in the premises of the Royal Society of Medicine on June 15th-17th. The President, Mr W. H. DOLAMORE, in his opening address, expressed his appreciation of the honour done him by his election as president for the second year in succession, and reviewed the efforts of the association to secure adequate dental treatment for our armed forces. The whole three days of the meeting were devoted to discussing war injuries and gunshot fractures of the jaws. Papers were read by—

Dr. V. H. KAZANJIAN, Harvard Surgical Unit, 20th General Hospital, France: Immediate treatment of gunshot fractures of the jaws.

Dr. O. RUBBRECHT, Belgian Red Cross, Professor of Stomatology, University of Ghent: A new method of treatment of fractures of the jaws.

Mr. G. E. SMITH, Cannes: Permanent bridge work as splints in fractured maxillae.

Mr. J. F. COLYER: Treatment of ununited fracture and malunion.

Captain H. M. HOLT, R.A.M.C.: Diet, massage, and dynamic exercises.

Discussions were opened by Mr. MONTAGU HOPSON, on reduction of misplaced portions of bone by immediate and gradual methods and retention of parts in normal position during the period of union; by Mr. J. E. SPILLER, on restoration of lost parts by prosthetic apparatus; and by Dr. PONT, of Lyons, on restoration of lost portions of the jaw by surgical means.

There were demonstrations on the making of masks for facial wounds, by Lieutenant DERWENT WOOD, A.R.A.; on restoration of soft external tissues by flexible material, by Mr. H. BALDWIN; and on a rapid method of producing special trays in metal for impressions of fractured jaws, by Mr. G. BRUNTON. A good museum of splints and apparatus was on view, which included a very useful extra-oral splint with pad attachments for supporting soft parts and flaps of plastic operations from the outside (V. H. Kazanjian), and specimens of Dr. G. Villain's "directing rods" for use in cases of deviation of the mandible after ununited fracture.

In the course of the discussions the desire for early co-operation between surgeon and dentist was freely stated. Hopeful opinions as to the possibility of bone-grafting were expressed by Dr. PONT, who claimed considerable success in cases of loss of portions of the mandible, but these hopes were not shared by all the speakers.

Considerable divergence of opinion was disclosed as to the treatment of ununited fractures, and especially of cases in which there was limited loss of continuity of the horizontal ramus of the mandible. Mr. COLYER, on the one hand, urged that bony union should be the primary consideration; on the other hand, many, including Dr. VILLAIN and Dr. KAZANJIAN, urged that normal occlusion of the teeth should be the paramount consideration, even at the risk of obtaining only fibrous union. Dr. VILLAIN showed that by means of a "connecting rod," which is fixed in various ways to the remaining teeth, a normal and powerful occlusion could be obtained. Mr. COLYER urged that bony union, even at the cost of loss of normal occlusion, left a permanent solid base independent of later loss of teeth. In cases in which the loss of bone concerned the horizontal ramus of one or other side he demonstrated his method of extracting the teeth, both upper and lower, on the injured side, thus allowing the smaller posterior fragment to be tilted up and brought into actual bony contact with the larger fragment. Union then took place with the larger fragment displaced to the injured side, but this, as Mr. Colyer demonstrated in cases drawn from the Croydon War Hospital, could be remedied by forcible pulling towards the uninjured side and the use of an "interdental splint." Mr. Colyer's method was to stretch at intervals, splinting between whites, till a good occlusion on the uninjured side was obtained. This he found soon became the permanent position of the jaw. He emphasized the value of extraction of all teeth whose roots reached the line of fracture in cases of ununited fracture.

Dr. RUBBRECHT's innovation in the treatment of fractures of the jaws consists in making separate frame wire splints for each part of the fracture. These splints are fixed by bands to the teeth, the fractured parts brought into position, and the separate parts of the splint soldered together *in situ*.

Captain HOLT read an interesting paper detailing the steps from "fluid" to "full" diet which he had worked out at the Croydon War Hospital. The whole dietary was contained within the limits of the army diet scale, but was nevertheless very varied and well suited to its purpose of educating the injured jaw back to dealing with ordinary food.

Reviews.

PSYCHO-ANALYSIS.

DR. JUNG was formerly a hypnotist; he then became a disciple of Freud; and later he broke away from some of the teaching of his master and has preached a modified doctrine of psycho-analysis, which does not, however, differ materially from that of the Viennese professor. Some of Dr. Jung's writings have now been translated into English and published in a volume of considerable size, entitled *Collected Papers on Analytical Psychology*,¹ edited by Dr. Constance Long. "Analytical Psychology" is not an appropriate title for the book, which deals with very different subjects, from very different points of view, from those treated of in the *Analytical Psychology* of Dr. Stone, which is now become a classic. The book treats, not of analytical psychology in the current and accepted sense of that term, but of psycho-analysis, which is a very different thing. The first ninety-three pages are occupied by a chapter entitled "The Psychology and Pathology of so-called Occult Phenomena," a chapter containing very little psychology, and very little pathology, but a long and detailed exposition of various manifestations of spiritualism, table-turning, automatic writing, and the usual gibberish of the spiritualistic "mediums." Although Dr. Jung makes some little attempt to explain them as pathological phenomena, he does not entertain, or at least he does not discuss, the hypothesis that any of them is due to deliberate imposture; if he has any doubt that the "communications" really emanate from the "spirits" he does not obtrude that doubt. He then explains the procedure of psycho-analysis, and initiates the reader into the mysteries, now becoming familiar, of the Oedipus-complex and the Electra-complex, laying down as an axiom that when a marriage is "crippled" through the neurosis of a wife, "the cause of the unhappiness always lies in a too firm attachment to the parents." No proof of this assertion is given. No evidence in its favour is advanced. No reason for it is assigned. It is stated as a fundamental truth, and apparently as a self-evident truth—an axiom.

The author relates how he discovered by psycho-analysis out of three persons the one who had committed a theft. The process was extremely elaborate, and is illustrated by five tables of reaction-times, percentages, complex indicators, and so forth, tables that it requires an expert to appreciate. The reader, however, is most impressed, not by the tables, but by the naïve admissions of the analyst, that the thief turned out to be "precisely the one most suspected"; that on being examined she "showed marked excitement," which the others did not; that her pulse went up under the ordeal to 120, while the pulses of the others were unaffected; that she "evinced a very 'suspicious,' or I might say almost 'impudent' countenance"; and that the analyst set about adding up the results "with the definite idea of finding in her the guilty one." It would have been strange if in these circumstances he had arrived at any other result, and we may suspect that it could have been just as well achieved without the use of psycho-analysis.

It is in the interpretation of dreams, however, that the real strength of psycho-analysis is displayed and that its greatest value is found. Dream analysis, we are told, is the *real instrument* of psycho-analysis. For instance, a

¹ *Collected Papers on Analytical Psychology*. By C. G. Jung, M.D., LL.D., formerly of the University of Zurich. Authorized translation edited by Dr. Constance E. Long. London: Baillière, Tindall, and Cox. 1916. (Demy 8vo, pp. 410; 14 figures. 12s. 6d. net.)

little boy of 8 years old dreams of a *black snake* which *wants to bite his face*. (Italics in original.) "The infantile attitude here, it is evident (italics not in original) is nothing but infantile sexuality." A married man, who was engaged in an intrigue, dreamt of the number 2477. This is very easily explained. The psycho-analyst adds together the dates, in days of the month, on which the births took place of the patient, his mistress, his wife, his mother, and his two children, having previously taken the number of the month on which these events severally took place, and put it sometimes before and sometimes after the day of the month. The 26th of February, for instance, becomes either 262 or 226. The sum of these numbers comes to 2416, which does not agree with the dream number. However, the patient's age is 36 and his mistress's age is 25. Add these, and we get the dream number 2477. Could anything be more convincing? Unfortunately, beyond that "it led to a deeper layer of the dream's meaning," we are not told what it signifies. It may be pointed out to Dr. Jung that the number 2477 may bear a different significance. If we take from this number the number of the year 1915 we get the number 562, and it is exactly 562 years since the Turks conquered Greece, and 562 miles from Zurich to Belgrade. This seems to lead to a much deeper layer of the dream's meaning. The same patient subsequently dreamt of the number 315. The psycho-analysis of this number produces a separation into 3-1-5. This means that the doctor has three children, and just lately there is one in addition, and the patient himself would have five children if all were living. There are several other analyses of dream figures, equally instructive and revealing. Mr. Ignatius Donnelly never produced any cryptogram half as convincing. Can any one, after this, fail to agree with Dr. Jung when he says that "psycho-analysis no longer appears to be a mere reduction of the individual to his primitive sexual wishes, but it becomes clear that, if rightly understood, it is a *highly moral task of immense educational value*."

SERUMS AND VACCINES.

THE third edition of the excellent little book on *Serums, Vaccines, and Toxins*,² by BOSANQUET and EYRE, has appeared seven years after the second, and shows evidence of compression as well as of bringing up to date. It begins with a full account of immunity and resistance to disease; here the authors follow Ehrlich in calling chemotherapy by the name "chemotherapy," as though the art were that of therapy by "chemosis," or oedema of the conjunctiva, rather than by "chemia" or chemistry. Then follow chapters on the preparation and administration of serums and vaccines, and the use of serums and toxins in diagnosis. The rest of the volume is occupied with the employment of serums and vaccines in the various diseases in which they have been found to be most serviceable. The facts are well presented, and the book is well written; on page 23 the structural formula of symmetrical trinitrophenol is given by mistake for that of trinitrobenzene. The book may be warmly commended to the attention of medical students and practitioners who are on the lookout for a simple account of the subject with which it deals.

Applied Immunology,³ by Drs. THOMAS and IVY, is a rather loosely written work, in which the general practitioner may read about the practical employment of therapy by serums and vaccines. The text deals with laboratory work at least as much as with the treatment of patients. A few references to the very extensive literature of the subjects dealt with are given, mostly from recent American periodicals. The text appears to be of the nature of a compilation, speaking generally, rather than an account based on extensive personal acquaintance with the methods advocated, although a number of charts illustrating cases are introduced. An appendix contains an account of chemotherapy and the use of salvarsan.

² *Serums, Vaccines, and Toxins in Treatment and Diagnosis*. By W. C. Bosanquet, M.A., M.D. Oxon., F.R.C.P. Lond., and J. W. H. Eyre, M.D., M.S. Dunelm., F.R.S. Edin. Third edition. London, New York, Toronto, and Melbourne: Cassell and Co., Ltd., 1916. (Cr. 8vo, pp. 464; 17 figures, 2 charts. 9s. net.)

³ *Applied Immunology: The Practical Application of Sera and Bacterins Prophylactically, Diagnostically and Therapeutically. With an Appendix on Serum Treatment of Hemorrhage, Organotherapy, and Chemotherapy*. By B. A. Thomas, A.M., M.D., and R. H. Ivy, M.D., D.D.S. Philadelphia and London: J. B. Lippincott Co., 1915. (Med. 8vo, pp. 370; 68 figures, 5 plates. 16s. net.)

NOTES ON BOOKS.

DR. R. B. FAULKNER of Columbia University has compiled a pamphlet⁴ in which he arrays the opinions of medical men and professors of the art of singing who do not believe in the operative removal of enlarged tonsils. Indeed, he goes so far as to conclude that "children with large tonsils are always large, well grown, and healthy." He appears to regard enlargement of the tonsils as due to misuse of the voice in some cases. He holds that the condition can be cured, and should be cured, if cure is required, by medical treatment. Medical men in Great Britain see very large numbers of cases of tonsillar enlargement, and have a wide experience of the benefits that result from the removal of enlarged or diseased tonsils in many cases. It is doubtful whether they will find themselves in agreement with all Dr. Faulkner's conclusions.

Dr. E. M. MAGILL's *Notes on Galvanism and Faradism*⁵ is a little textbook intended for the use of masseuses preparing for examinations in medical electricity now held by the Incorporated Society of Trained Masseuses. It is divided into three parts, defined as "galvanism" (in which static electricity is included), "faradism," and "currents from the main." It is clearly written, but the authoress is not rarely astray in her statements of fact. Thus it is incorrect to define static electricity as "electricity at rest" (p. 16). To say that the common electrical units "have been chosen arbitrarily by electricians" is to ignore the scientific basis of the whole C. G. S. system of units (p. 37). The ohm is not the measure of the resistance of a given column of mercury "1 millimetre in cross section" (p. 38). "Treatment by diathermy appears not to receive any notice. In Fig. 21 on p. 54 the cells in use are wrongly numbered. Much of the text is excellent, and the book would seem to be well designed for the purposes for which it is intended.

⁴ *The Tonsil and Its Uses: Vocal, Mechanic, and Physiologic*. By R. B. Faulkner, M.D., Columbia University. Pittsburgh, Pa.: The Blanchard Co., 1916. (Cr. 8vo, pp. 29. 1 dol.)

⁵ *Notes on Galvanism and Faradism*. By E. M. Magill, M.B., B.S. Lond., D.P.H., R.C.S.I. (Hons.). London: H. K. Lewis and Co., Limited, 1916. (Cr. 8vo, pp. 235; 67 figures. 4s. 6d. net.)

THE MEDICAL INSURANCE AGENCY.

THE Committee of the Medical Insurance Agency, at its meeting on June 15th, was able to allot further substantial sums to medical charities: to the Royal Medical Benevolent Fund, £150; to the Royal Medical Benevolent Fund Guild, £100; to the Epsom College Benevolent Fund, £100; to the Royal Army Medical Corps Officers Benevolent Fund, £25; and to the *Lancet* Editor's Fund, £25.

Before proceeding to this part of the business, the chairman, Dr. G. E. Haslip, presented the balance sheet for the year ending December 31st, 1915, audited by Messrs. Price, Waterhouse, and Co., and reviewed the work of the Agency during that year. In spite of adverse circumstances due to the war the business of the Agency had expanded, and it had earned in commission £1,950, as against £1,816 in the previous year. Out of this sum £838 had been returned to those insured through the Agency, representing a direct saving to them. After paying working expenses the sum of £725 remained over for medical benevolence. Of this amount £630, or just double that distributed in the previous year, was allotted to various medical charities, and £95 was carried forward to be dealt with in the current year. The serious problem which medical men liable to military service had to face owing to the fact that most life offices either declined the risk outright or required such a heavy additional premium as to make the business prohibitive for most men, was taken up early by the Agency. It succeeded in arranging with an office of high standing to accept assurances at more reasonable rates, and the terms have proved acceptable to many medical men who might otherwise have had to take up military service without being able to provide against the contingency of death. The motor business was good during the year, and there was, in fact, an expansion under each head of insurance, while the working expenses were lower than in the previous year. Summarizing the work of the Agency since its initiation, Dr. Haslip said that it had been able to return as a direct benefit to those insured through it £4,530, representing a real saving to the medical profession, and the Agency had distributed £1,700 to medical charities down to the end

of 1915. With the amounts allotted at the meeting on June 15th, the total distributed to medical charities from the first amounted to £2,100. The Chairman concluded by recommending the Committee, in accordance with precedent, at once to make the interim grants mentioned in the opening of this article from moneys accumulating in the Medical Benevolence Account since the beginning of the year, and this was done.

The amounts allotted during 1914 and 1915 and for the first six months of this year are shown in the following table:

Grants.	1914.	1915.	1916, First Six Months.
	£ s. d.	£ s. d.	£ s. d.
Royal Medical Benevolent Fund ...	105 0 0	230 0 0	150 0 0
Royal Medical Benevolent Fund Guild	52 10 0	160 0 0	100 0 0
Epsom College Benevolent Fund...	78 15 0	145 0 0	100 0 0
Royal Army Medical Corps Officers Benevolent Fund	—	50 0 0	25 0 0
Royal Medical Benevolent Fund Society of Ireland	26 5 0	30 0 0	—
Royal St. Anne's School ...	10 10 0	15 15 0	—
Lancet Editors' Fund ...	15 15 0	—	25 0 0
Belgian Doctors' and Pharmacists' Relief Fund	26 5 0	—	—
Total ...	£315 0 0	£630 15 0	£400 0 0

This result cannot but be satisfactory to all those medical men who have insured through the Agency; not only has there been a considerable saving in their own expenditure, but it has been possible to make substantial contributions to medical charities without making any call upon the finances of the profession itself. We believe that the advantages and aims of the Agency have only to become more widely known in order that the financial assistance it will be in a position to give to medical charities in future years shall be even more substantial. The success of the Agency is very encouraging, and reflects the greatest credit upon the chairmen. The first chairman was the late Dr. Radcliffe Crocker, and on his death the office was accepted by Dr. G. E. Haslip, who has taken the greatest possible interest in the work, as has the Agent and Secretary, Mr. Guy Elliston, from whom particulars of the policies—life, accident, motor-car, and others arranged to meet various needs—can be obtained on application to the Agency, at 429, Strand. The Committee has lost by the regretted death of Sir Frederic Hewitt, a member nominated by the *Lancet*, who always showed deep interest in its work and greatly assisted in making it better known. The vacancy thus caused will be filled at a subsequent meeting of the Committee.

"NEURONE" OR "NEURON."

By W. M. BAYLISS, F.R.S.,

Professor of General Physiology, University College, London.

I MAY perhaps be permitted to make a few further remarks on this question, since it appears from various representations made to me that an agreement on the spelling of the name is desirable.

It is stated by Barker in his *Nervous System* that the Greek word from which Waldeyer derived the name which he suggested for the nerve cell, including all its processes, is "νευρών." If this be accepted, it is clear that, in order to make the *o* long, it must be spelled in English with a final *e*, just as, in fact, it was spelled in French from the first. But, on referring to the course of lectures given by Waldeyer in 1891 (published in the *Deut. med. Woch.*, 17), in which it is generally stated that the name was originally suggested, I have been unable to find any mention of the Greek word from which it was formed. Indeed, no use is made of the new name until the summary in the last lecture (p. 1352), where it appears in brackets in the plural form, "Neuronen," as an alternative name for "Nerven-einheiten." It is possible that the derivation may be given in some other publication, but I have been unable to trace it. Further, as Professor Sherrington has pointed out to me, the word *νευρών* is

not to be found in classical Greek; we have *νεύρον* or *νευρά*. It must therefore be a coined word. Professor Barker refers to the opinion of a Greek scholar that it would be justifiable on the analogy of *παρθενών*, the part of the house set apart for the young women. Thus it may be taken as suggesting something on a higher scale, or greater degree of complexity, than would *νεύρον*, itself an appropriate name for the axis-cylinder process, which forms the unit element of the nerve trunk. It may be remembered that Sir Edward Schäfer proposed this use, although it has not met with general recognition. Notwithstanding the somewhat doubtful etymology, it seems preferable on the whole to adopt the spelling "neurone," partly in remembrance of the proposer, partly because this is the spelling used by the greater number of English-speaking neurologists, and also because it serves to convey the suggestion of a compound unit built up of constituent parts.

However much we may regret, with Sir Edward Schäfer, that it has been found necessary to have a special name for the nerve cell merely on account of the confusion caused by its happening to possess a particularly long process, the word "neurone" cannot now be displaced. It must be admitted, nevertheless, that the suggestion is apt to be conveyed to the student that the degeneration of a nerve fibre is a totally different process from that which occurs in a part of any cell when separated from the nucleus.

As to the names for the constituent part of the neurone, it is unfortunate that the Greek *ἄξων* has the *o* long. If we take the point of view put forward above, it is certainly preferable to use the form "axon" for the axis-cylinder process. This, indeed, appears to be the usual custom. It may reasonably be held that the precise etymological form of a word should not militate against a spelling which is of more scientific value. The distinction between "axon" and "neurone" in respect of the final *e* serves to convey a physiological fact. It may be said also that *ἄξων* is the root. Similarly, "dendron" is the best form for the other processes, while "dendrites" may be used for the finest ramifications, as is, in fact, done by Dr. Mott. No satisfactory name has yet been suggested for the body of the cell containing the nucleus. Waldeyer himself speaks of it as the "nerve cell." But this is clearly misleading. Indeed, it seems almost impossible to avoid the conclusion that the use of "nerve cell" will have to be discontinued altogether. "Cell body" is sometimes used for the part surrounding and including the nucleus, although a name which implies the presence of the nucleus would be preferable. "Peri-karyon" has been suggested, but it seems to exclude the nucleus itself, and is rather clumsy. Would "karyon" serve? I think it need not be supposed to refer to the nucleus alone since we have another name for that, but doubtless a better word may be found.

I would, then, venture to suggest that we should agree to use "neurone" for the whole nerve cell, "axon" and "dendron" for the parts. This, indeed, conforms to the practice of Dr. Mott and others; it also has the approval of Sir Edward Schäfer. "Neuron," as liable to ambiguity, should be dropped altogether.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the committee, held on Tuesday, June 6th, eighteen cases were considered and £190 was voted to seventeen of the applicants. The following is a summary of the cases relieved:

Widow, aged 40, of L.R.C.P. Edin. who practised at Cliffoney, co. Sligo, and died in 1912. After her husband's death applicant opened a sweet shop in Scotland, and managed to get on until she had to undergo an operation in May, 1915. The Fund then made her a grant of £10. In April, 1916, her shop was blown up by a bomb from a Zeppelin, and all her stock and furniture destroyed, and she was not insured. Now wants help to re-establish herself. Voted £15.

Widow, aged 45, of L.R.C.P. Edin. who practised in the East End of London and died in December, 1915. Applicant is partially paralysed, and was left practically unprovided for at her husband's death, and has had to live on the small sum the practice realized, of which only about £70 is left. Has one son, aged 6 years. Has no home, and is staying with relatives who have promised to give all they can, which only amounts to £13 per year. Voted £10 in two instalments.

(To be continued.)

British Medical Journal.

SATURDAY, JUNE 24TH, 1916.

A SLOVENLY SCHEME.

MEASURES are being taken for the formation of an Auxiliary R.A.M.C. Benevolent Fund to embrace the three Auxiliary branches of the corps—namely, the Special Reserve, the Territorials, and those holding temporary commissions in the R.A.M.C. A Provisional Committee has already met, and has formulated a scheme for two funds—one a benevolent fund for officers' orphans, the other a relief fund for the widows and orphans of the rank and file of the auxiliary R.A.M.C. forces. With the latter we do not propose to deal, beyond suggesting that the officers of the Auxiliary branches are unlikely to be possessed of a superfluity of this world's goods, so that, on the principle that each group or class of individuals should concentrate its efforts, as far as possible, on relieving the necessitous in its own group or class, it might be well that the attention of medical officers should be directed principally to the benevolent fund scheme, with any extensions that may seem desirable. Such extension is already contemplated by the Provisional Committee, which has resolved to recommend the general meeting to be held at the Royal Army Medical College, Grosvenor Road, London, S.W., at 2.45 p.m. on Monday next (June 26th) to appoint "a committee to report to a further meeting on the possibility of the establishment of a loan fund to help medical officers of the auxiliary forces who are in temporary difficulties on returning to their civil practices."

It is proposed that the Auxiliary Officers' Benevolent Fund should be run on the lines of the R.A.M.C. Officers' Benevolent Society as far as they are applicable. The scheme proposes that the Fund should apply only to orphans in necessitous circumstances, and should be especially concerned to assist in their education and starting in life. Only the orphans of such officers as subscribe should be entitled to benefit. A minimum subscription of one guinea a year is suggested, which would entitle the subscriber to vote at the annual meetings. Various recommendations are made with regard to the distribution of grants.

The proposal to establish a fund for the benefit of the orphans of officers of the Auxiliary Branch of the R.A.M.C. will, we do not doubt, be most sympathetically received, but the scheme drawn up by the Provisional Committee does not meet the situation. It is cramped and lacking in imagination. It has been perhaps too hastily prepared, and has sought to go into details, such as for instance the provision of a "marriage outfit," before general principles were considered. It demands no great effort of the faculty of imagination to conceive the case of a man who, though he survives, is disabled by wounds or disease. It is quite true that he will be entitled to a pension from the State, but so small that he will be hard put to it to find housing and food, and will be in no position to provide for "the education and the starting in life" of his children. The framers of the scheme seem quite to have forgotten him, and he may ask himself bitterly whether he were not better dead. There can be no hesitation in agreeing that

the fund proposed for orphans is urgently needed, since the auxiliary officer R.A.M.C. who is killed or dies on active service, leaving a widow and orphans, will usually be a man so recently started in practice that he will have been unable to make sufficient provision for the education of his children, or the maintenance of his family. His widow may not be equal to earning a sufficient livelihood; and the medical charities in existence do not offer unlimited assistance. Epsom College is valuable—to the extent of its vacancies. The Royal Medical Benevolent Fund makes grants—often to the extent of £12 a year. The Society for the Relief of Widows and Orphans of Medical Men is only open to subscribers, who must reside or have resided within twenty miles of Charing Cross. The Professional Classes War Relief has many calls from other professions.

We confidently submit that before drawing up rules for the Benevolent Branch and entering into such details as we have mentioned, the Committee ought to have settled matters of principle. Who are the persons to be benefited by the Benevolent Branch? Is there need for a loan fund, and what should be its purpose? To whom is the appeal for donations to be made? And what is to be the relation of the administration of the fund, or funds, to other funds? We hope that the promoters will study carefully how they may extend the usefulness of the proposed fund or funds to the fullest possible extent, and will not at the outset tie their own hands by a narrow scheme and narrow references.

Upon the first matter of principle we have already touched. We are confident that a scheme for orphans only will not appeal so strongly to the profession at large as would a wider scheme.

The second matter of principle is as to the need and purpose of a loan fund. The recommendation which the Provisional Committee is making to the general meeting shows a laudable desire to widen the original terms of reference, but we venture to say that this matter should be settled before any general appeal is made. There is a Government scheme for meeting cases of hardship arising out of civil liabilities applicable to all who joined the ranks since August 4th, 1914, or may hereafter join, and to single as well as to married men. It is not contemplated that the assistance granted in any individual case shall exceed £104 a year. The items in respect of which assistance will be granted are rent (including ground rent and rent of business premises), mortgage interest, payments in instalments in virtue of contracts such as purchase of premises, business, or furniture, taxes, rates, insurance premiums, and school fees. The scheme, however, does not apply to officers. Yet there must be many cases among medical officers of the Auxiliary R.A.M.C. in which the need for similar temporary assistance must be very urgent. To meet these cases a loan fund, if it can be formed, would be of the greatest value. But the limitation of such a fund to helping medical officers who are in temporary difficulties "on returning" to their civil practices seems unwise. Surely many cases of hardship must occur when the practitioner is going on service and while he is away. In considering the question of a loan fund, the endeavour should be to relieve the anxieties of an auxiliary officer from the moment that he is called up.

The next matter of principle which needs to be settled is as to the people to whom the appeal should be made. From the wording of the scheme it would appear that it is founded upon the rules of the Regular R.A.M.C. Officers' Benevolent Society, but

it seems to us to need no argument to prove that rules applicable to the regular service into which a man enters as a life's career cannot be transferred to civil practitioners temporarily in military employ without root and branch modifications. This point is, we think, clearly shown by the recommendation of the Provisional Committee that orphans of officers who are not subscribers to the fund should have no claim on its benefits, and to a further paragraph expressing the hope that every officer of the Auxiliary R.A.M.C. will at once become a subscriber and, if able to do so, give a donation to assist in starting the fund. This is to take far too narrow a view of the situation. Undoubtedly officers now employed should, and, we believe, will, respond, but the appeal ought to be much wider. There are, we believe, in fact we know, many members of the profession debarred by age or other circumstances from engaging in military service who feel strongly that there is an obligation upon them to do anything within their means to help their brethren who have joined the Forces of the Crown, by contributing to a benevolent fund or to a loan fund, or to both. In this way they will feel that, after all, they are able to "do their bit."

The final matter of principle is with regard to the relation of the Auxiliary R.A.M.C. funds to other funds already in existence. Care should be taken to avoid overlapping and the closest possible connexion established and maintained with such other funds. This might be attained by inviting representatives of other bodies to sit on the committee of the Auxiliary R.A.M.C. funds. It must be remembered that that committee will have to deal with men drawn almost entirely from civil practice, the large majority of whom will, after the war is over, revert to civil practice.

For these reasons we counsel the general meeting on Monday to make a clean slate, and refer the whole matter to a strong mixed committee containing a large proportion of men acquainted by experience with the special difficulties of Territorial, Special Reserve, and temporary medical officers, especially those who before the war were engaged in general practice, ready to give sympathetic consideration to those difficulties, and competent to interpret the feeling of the civil profession on the subject.

THE INCREASING MORTALITY FROM CANCER.

Two views as to the alleged increase in the annual mortality from cancer are generally held. One of these is entertained by the optimists, and explains away the increase as virtual, not real, and due to improved skill on the part of medical men in diagnosis and the filling up of death certificates. Holders of the other view—largely statisticians and experts—have long been asserting that there is a steady increase year by year both in the relative and the absolute number of persons dying of cancer. The Prudential Insurance Company of America has gone very thoroughly into the question, collecting the most complete and recent statistics bearing on it from all available sources, and has published all its facts, figures, and conclusions in a well-written volume of over eight hundred pages.¹ The main conclusion reached is, briefly, that the actual frequency of malignant disease throughout the civilized world is much more of a menace to mankind than has generally been assumed to be the case.

The general death-rate shows a marked decline; the death-rate from cancer shows an actual and

persistent increase in practically all the countries and large cities for which trustworthy data are available. Europe, Asia, Africa, and America are laid under contribution to prove this point, and vast quantities of statistics have been tabulated to illustrate it. Arguments that are apparently sound are brought forward to show that the increase in malignant disease is real, and not the result of improved diagnosis, more scientific classification, or a changed age distribution. Thus, combining the returns for the United Kingdom, Norway, Holland, Prussia, Baden, Switzerland, Austria, the cities of Denmark, the Commonwealth of Australia, and the Dominion of New Zealand, it appears that in 1881 these countries had an aggregate population of 98,380,000, and 44,047 deaths from cancer, equivalent to a rate of 44.8 per 100,000 of population. By 1891 the rate had increased to 59.6, by 1901 to 76.3, and by 1911 to 90.4. Thus during thirty recent years the cancer death-rate in these countries, which—excluding perhaps Prussia—are typical of the civilized portion of the world, has more than doubled. And this in spite of an important factor tending to reduce the death-rate from cancer, namely, the increasing practice of surgical operations for malignant disease; deaths must result to an increasing extent from causes other than cancer in the case of patients with malignant disease successfully operated upon in conformity with modern surgical practice. A further numerical illustration of the increase in the death-rate from cancer is furnished by combining the principal European countries for the period 1896-1900; it is found that the average rate during these five years was 69.1 per 100,000 of population. It was as high as 127.4 in Switzerland, and as low as 30.7 in Hungary. During the five-year period 1901-5 the average rate rose to 74.2, being 128.3 for Switzerland, 39.1 for Hungary. During the five years 1906-10 the average rate was 80.1; in Switzerland it was 125.9, in Hungary it had risen to 43.6. One of the highest recorded death-rates from cancer is that of the cities of Denmark, which stood at 142.1 for the quinquennium 1908-12. Consideration of these and other similar figures with which Mr. Hoffman's book abounds would seem to show that the optimists who seek to prove that there is no general increase in the prevalence of cancer throughout the world, and more particularly in highly civilized countries like our own, will have to reconsider their position.

Numerous interesting problems and side issues of the great cancer question are discussed in the volume. The mortality from cancer in different occupations is considered at full length, with many references to the abundant literature of the subject; cancer is also considered as a problem in life insurance medicine, and its geographical incidence throughout the world is discussed, so far as the imperfect statistical returns of the less civilized countries permit. It appears certain that cancer is exceptionally rare among primitive peoples, such as the North American Indians and the Esquimo population of Labrador and Alaska; though cancer of the cheek is common among chewers of the betel nut in Ceylon, and in Afghanistan malignant disease of the abdominal wall, or kangri cancer,² is often met with as the result of wearing a portable fire basket under the clothes for warmth.

Mr. Hoffman enters a strong plea for the importance of collecting cancer statistics on a uniform basis. At the present time cancer hospitals and the various associations interested in the problem of cancer collect their statistics and issue their reports

¹ *The Mortality from Cancer throughout the World*. By F. L. Hoffman, LL.D., F.R.S., F.A.S.A., Statistician the Prudential Insurance Company of America. Newark, New Jersey: The Prudential Press, 1915. (Med. 8vo, pp. 841.)

² E. F. Neve: *BRITISH MEDICAL JOURNAL*, 1910, i, 589.

as each thinks best. The results as reported are, therefore, not comparable one with another, and the figures given, commonly lacking in important particulars, are not as valuable as they easily might be made. There is every reason, therefore, for the general adoption of uniform methods of tabulation and analysis on the part of these institutions and associations; the special form in which the returns should be made is a matter for settlement by general discussion and agreement.

COMPULSION AND ENROLMENT.

COMPULSORY military service comes fully into force in Great Britain on this day, Saturday, June 24th, 1916. We have received several inquiries as to what a medical man of military age should at this moment do in view of this enforcement of all-round compulsion. The answer is, if he be enrolled—Nothing. The answer if he be not enrolled is—Enrol.

The compulsory clauses of the Military Service Acts apply to members of the medical profession under 41 years of age as to those of every other calling, but the most recent Act and the regulations made under it contain special provisions with regard to the tribunal by which their applications for exemption shall be heard and decided.

If a medical man has enrolled he may in the meanwhile possess his soul in peace. For him the procedure is very much simplified. The enrolment scheme evolved by the profession itself is similar to the Derby attestation scheme for the general population, but antedated it, and has, we conceive, been continued under the new Military Service Act for two reasons: first, because the original response of the profession to the first call of the country in 1914 was so good; secondly, because the enrolment scheme attained a respectable measure of success and was sound in principle, inasmuch as it was the only plan by which the medical needs of the military forces of the Crown could be met, while those of the civil population were safeguarded as fully as the great test to which the nation was being put allowed. Voluntary effort produced five million men and over ten thousand medical men. A large army and a large medical service, but an army and a medical service undergoing constant wastage—according to the law of averages; so many men a week in every branch have to be sent home, a large proportion of whom will never be fit to rejoin.

Now compulsion has come, and it applies to medical men of military age as to men of military age in any other calling. The only difference is that medical men have the privilege of applying to a special professional tribunal; their case is to be tried by their peers—a very good old English principle. These tribunals, styled "Central Professional Committees," are now recognized by the Order made by the King in Council under Section 7 of the second Military Service Act, the new Act which applies compulsion to all men of military age whether married or single. The statutory Central Professional Committees in England and Wales are the Central Medical War Committee (429, Strand, London, W.C.), with, for the staffs of hospitals in the County of London and for certain other cases specially referred to it, the Committee of Reference formed by the Royal Colleges in London (Conjoint Board in England, Queen Square, Bloomsbury, London, W.C.). In Scotland the Statutory Committee is the Scottish Medical Service Emergency Committee (Royal College of Physicians, Edinburgh). To the secretaries of these committees any inquiries

that may be considered necessary should be addressed. As a matter of fact no inquiry should be necessary. The position, to any one who has read the public newspapers and medical papers, is as plain as a pike-staff. Every person should make himself acquainted with legislation by which he is, directly affected; ignorance of the law, is no excuse.

A medical man who has enrolled knows exactly what his position is. He has been told that he will receive a month's notice before his services are required. Until he receives this notice he need do nothing. The procedure of the statutory Central Professional Committees, which received official recognition from the Army Council only last week, has not yet been settled, but an enrolled medical man will in practice probably receive rather more than a month's notice. In any case it will not be until he is warned that he need take any action to obtain exemption, should he desire exemption. He should then, and not before, prepare his case and submit it, with any evidence he desires to advance, to the appropriate Professional Committee, which will be bound to hear him and his witnesses if any, should he so elect.

As to the medical man who does not enrol, we do not pretend to say what excursions and alarms may be his lot, but eventually, if he does not want to serve in the ranks, his case will go before the appropriate Professional Committee, where it will be heard and decided.

Nothing hereinbefore stated applies to Ireland, which has contracted out of compulsion. But members of the medical profession in Ireland are free to volunteer for commissions in the R.A.M.C., and we believe that a good many have already done so, though we have not been supplied with figures. It will, however, have been seen that not a few boards of guardians and other local authorities in Ireland have granted leave of absence to their medical officers. Medical men in Ireland willing to offer their services should address themselves to the secretaries of the Irish Medical War Committee, 16, South Frederick Street, Dublin.

COMMISSIONS FOR MEN BETWEEN 45 AND 55.

We understand that the appeal of the War Office to medical men between 45 and 55 to accept commissions in the R.A.M.C. for whole-time general service in the United Kingdom is urgent, and that it is very strongly hoped that the response may be large and immediate. Those who thus offer themselves for whole-time general service in the United Kingdom will set free to serve with the British armies abroad younger medical officers now employed in this country. The military correspondent of the *Times*, who has often proved himself to be very well informed, published in that paper on June 20th a letter, dated from Northern France, in which he said: "We have continually growing numbers of men and guns and better preparation for our next effort. The stream of troops and of drafts which reaches our front flows ceaselessly, and we receive constant proofs of the admirable efforts made by those who direct our strategy at home towards the building up of a formidable army." After referring to the feat of the French in holding up, all by themselves, for four months, the German enemy on the Meuse, to the extraordinary successes of the Russian Southern armies, to the arrest of the Austrian offensive against Italy, to the resuscitation of the Serbian army, and to the effects of the naval battle off Jutland, as well as to certain evidences of the decline of German man power, he went on to say, "With all these circumstances to our credit the fact remains that the German fighting machine is still intact, and has to be broken down before we can think of peace. This task remains an exceedingly hard one, and not one

man, or gun, or shell can legitimately be spared from its accomplishment. We cannot afford to reduce Germany by starvation alone. She must be beaten in the field, so that the ruling military caste may be convinced, as profoundly as the poor people of Germany appear to be convinced, that the game is up. . . . What we can say with confidence, after reviewing the whole position, is that the conditions are favourable to us, and that it only remains for generalship and hard fighting to take advantage of them." Hard fighting! Field-Marshal French, in ending his tribute to Lord Kitchener in the House of Lords on Tuesday, said that the finest monument the British people could erect to this great man's memory "is to clothe themselves in the spirit of determination and concentration of effort which characterized his public career." The voluntary effort already made by the medical profession has been so splendid that we feel confident that this fresh appeal to men between 45 and 55 will meet with a response at least as good as that given by their juniors. Offers of service—which, we repeat, must be for whole-time service in any part of the United Kingdom to which the officer may be directed to go—may be made to the Secretary of the War Office, Whitehall, London, S.W.

GERMAN TREATMENT OF PRISONERS OF WAR.

A WHITE PAPER recently issued contains correspondence between Sir Edward Grey and Mr. Page, the United States Ambassador, and a *Note Verbale* from the German Government concerning the employment of prisoners of war. From this it appears that 1,950 German combatant prisoners of war have been transferred from internment camps in the United Kingdom to Rouen and Havre, where they are engaged, under British supervision, in clearing cargo ships of goods other than munitions of war. It is added that the treatment of a camp in France is precisely similar to that of one in England. By way of reprisals the German authorities transferred 2,000 British prisoners from camps in Germany to Russia, where it was said they would be put to work under the same conditions as those obtaining in the case of the German prisoners sent to France. Sir Edward Grey arranged for inspections by representatives of the United States Ambassador in Paris of the dépôts in France to which the German prisoners had been sent. He added an expression of his hope that it might be found possible to arrange for an inspection of the British prisoners very shortly after their arrival at their destination, and suggested to Mr. Gerard that it might prove of great advantage if one of the doctors now attached to his staff could be delegated to reside for this purpose at some place in Russian territory under German occupation as long as British prisoners were interned in that territory. One of these places is Windau, a Baltic port, where the prisoners are engaged in railway work. The *Daily Mail* has published some evidence as to their treatment. According to statements by prisoners, they rise at 4 a.m. and work, with short intervals, till 5.30 p.m. Food is scarce, and parcels are not received; water to wash in is not to be obtained. Some of our newspapers speak of this transfer of prisoners as a new step taken by our Government. But it would seem that the Germans began it. The first batch was sent from this country on April 5th. According to the *Paris Journal*, about the end of March some thousands of French prisoners were transferred from the camps of Westphalia, the Grand Duchies of Baden and Saxe-Coburg-Gotha, Münster, and other places, to Russia, Poland, and Courland, by way of reprisals for the sending of a number of German prisoners to Morocco and Dahomey, where, it was alleged, they were ill-treated. *Le Journal* says this allegation is open to the gravest doubt, and the character of German official veracity does not stand so high that such statements can be received without the most cautious reserve. The testimony of the French prisoners as to the way in which they

are treated strongly confirms that of the British. They are stationed in places the climate of which is notoriously unhealthy, the conditions being made worse by exceptionally bad weather. They do not receive the letters and parcels which their families send. They are badly housed, badly fed, and are compelled to do work for which they are altogether unfitted. Some are set to work in the marshes in water halfway up the leg, cutting out peat from 6 to 6 in all weathers, or carrying stones to break for the roads. Men repatriated from Germany bear testimony to the brutality of the Germans. They were tied to posts for refusing to do munition work, and punished with twenty-eight days' cells on black bread and water.

PLAN OF NEW PRISON CAMPS IN GERMANY.

The Germans still profess indifference to the feeling of repulsion excited in other nations by the low ethical standard they have displayed in dealing with the problem created for them by the prisoners they have interned or captured, but there is some evidence that they are becoming awake to the contempt for their powers of organization and administration aroused by the incapacity shown in handling it. A camp at Cottbus for Russian prisoners was visited by a severe epidemic of typhus, as has happened in many other German prison camps. The conditions of the camp must have been very bad, for 500 of the prisoners who survived were set to work to build a new camp in the same neighbourhood to provide accommodation for 10,000 prisoners. It is reported to have been completed last July, and is said to have served as a model on which new prisoners' camps in Germany have subsequently been built. In the early camps barracks were run up in parallel rows, and stood completely above ground. The barracks of the Cottbus type are dug in so that only the upper half of the building is above ground. The barracks are disposed like a fan spread out over a half-circle. It is claimed for this arrangement that the buildings are much warmer than those built wholly above ground, and that their concentric distribution facilitates the supervision of the whole camp from the central observation station. Early in the war one soldier was required to guard every ten prisoners, but with the new plan only one soldier is required for every twenty prisoners.

GRADUATED WORK FOR THE TUBERCULOUS.

WAR teaches many lessons. The physical fitness of the individual for the work that he is called upon to do has been forced into prominence by the "recruiting problem." There is no hard-and-fast line to be drawn between the fit and the unfit. For the latter class there is work to be found, and there is no longer any excuse for a physically strong man to be employed upon work that does not require physical strength if it can be equally well done by a weaker one. Among the large number of adult males who are unfit to face hardships there is always a very considerable proportion who are actual or potential consumptives, and experience is giving abundant proof that the incipient disease, if intelligently handled, is no bar to usefulness within reasonable limits. The tenth annual report of the National Sanatorium Association, which describes the system adopted at the Benenden Sanatorium, affords striking evidence of the extent to which the period of treatment may be turned to good account by the employment of graduated exercise in the form of productive labour, with due observance of the needs of each individual case. While the hours for sleep and for meals are fixed for all patients alike, the time to be devoted to exercise in any form is strictly prescribed for every patient separately. By successive stages a period is reached when productive work can be undertaken, and the steadily increasing development of the land surrounding the main building of the sanatorium gives convincing evidence of the fact that consumptive workmen, if enabled to live a strictly hygienic life, are capable of the best class of productive labour. Among sanatorium

patients there are always a certain number, usually too many, with whom the disease has progressed too far to admit of anything but very easy work. For them special methods have been tried at Benenden, as elsewhere, but neither the numbers treated nor the results achieved are sufficiently striking to warrant any conclusions. The general results do not vary greatly from year to year. A somewhat different form of classification, as suggested by Sir R. W. Philip, has been adopted whereby the amount of systemic disturbance is taken into account in addition to the extent of the local lesions (Turban's system). But the ultimate outcome is much the same and only serves to emphasize the truth of the universally recognized rule that treatment in the earliest stages gives the best chance of success.

SPHAGNUM MOSS AS A SURGICAL DRESSING.

In a paper published in the *BRITISH MEDICAL JOURNAL* nearly a year ago (July 24th, 1915), Mr. Charles W. Cathcart, surgeon to the Royal Infirmary, Edinburgh, called attention to the value of sphagnum moss properly dried and prepared. Since then great progress in the organization, collection, and preparation of the moss has been made by the Scottish War Dressings Supply Organization, which has from time to time extended its work-room accommodation in Edinburgh to meet the demand. At present the secretary's office and central workrooms are at 37, Palmerston Place, where information can be obtained; the receiving dépôt and storerooms are at 10, Queensferry Street; the sublimating and compressing workrooms, instituted by Sir John Cowan, are at Messrs. Redpath, Brown and Co.'s workshops in Albion Road; and the packing and dispatching dépôt is at the West Gate, Royal Infirmary. In a communication to the *Scotsman* last week, Mr. Cathcart said that the Director-General, A.M.S., had placed sphagnum moss on the list of materials approved by the War Office for surgical dressings, and that large orders for military hospitals were being received. Four sub-centres have been established at Lerwick, Aberdeen, Oban, and Beattock, from which consignments of moss collected from the surrounding districts are dispatched to Edinburgh, free of charge. Professor I. Bayley Balfour, and the staff of the Royal Botanic Garden, Edinburgh, have given much valuable assistance and advice, and Mr. W. W. Smith, assistant keeper of the garden, has made careful survey of the moorland districts round Edinburgh, and has prepared a report indicating where the best moss grows on the Pentlands, Moorfoot Hills, and Lammermoors, as well as on the Moffat Hills, the Eildons, and Ettrick Forest. Mr. Cathcart added that he had received communications from surgeons of military hospitals stating that the moss had proved a most serviceable dressing. A Lieutenant-Colonel R.A.M.C., writing from Alexandria, said: "It is very absorbent, far more so than cotton-wool, and has a marked deodorizing power." An officer commanding one of the Territorial hospitals in London stated that the moss had been found most valuable and efficient, and other officers in similar positions have borne similar testimony. Mr. Cathcart concludes by making an appeal for a sum of at least £500 to carry on the work for another twelve months, and asks that subscriptions should be sent to the Honorary Treasurer, Mr. A. G. Miller, F.R.C.S., 36, Alva Street, Edinburgh.

THE HEALTH OF THE GERMAN CHILD.

In the German lay press it has been repeatedly stated that the Allies' blockade has not affected the health of the children in Germany, taken as a whole. This view of a most important matter is not shared by Dr. A. H. Kettner, school medical officer in Charlottenburg, who even last autumn gave a rather gloomy account of the health of the school children in his district. He alleged that within six months of the outbreak of war the adults of the working classes were underfed. This was not at

first the case with the children, at any rate with very young children. The action of the Government in subsidizing the suckling mother helped to ensure that children in the first year of life should be as healthy and vigorous as before. Children to the end of the sixth year also seemed to have escaped any serious effects of the war, their parents in many cases having made great sacrifices. Two diseases had, however, increased among children on account of the war. The first was rickets, due, apparently, to poverty in the homes, and tetany or the spasmophil diathesis, which was the result of the excitement of the war reacting on the young pregnant mother. As late as the spring of 1915 Dr. Kettner reported to his school board that the war had left no trace on children of school age. In this impression he was supported by the teachers and superintendents. But when, in June, the yearly weighing and measuring of the scholars took place, the fallacy of his optimistic report in the spring was revealed. The figures compared most unfavourably with those for previous years. Increase both in weight and height had been checked in all the classes from the eighth to the fourteenth year; girls suffered more than boys. Of a class of 33 girls aged on the average 10 years, weighed early in February, 1915, and again five months later, at the beginning of the summer holidays, 27 had lost weight, the loss amounting to as much as 2 kilos in some cases, two were as heavy as before, and the rest had gained weight, the gain in these cases being much below the average gain under the same conditions in time of peace. Various measurements of the children in this class told the same tale of stunted growth.

THE HALF-YEARLY INDEXES FOR 1916.

THE usual half-yearly indexes to the *JOURNAL*, to the *EPITOME*, and to the *SUPPLEMENT* have been prepared and will be printed. They will, however, not be issued with all copies of the *JOURNAL*. Any member or subscriber who desires to have one or all three of the indexes can obtain a copy of what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C. Such copies will be dispatched shortly after the middle of July.

SIR ALFRED KEOGH, K.C.B., Director-General of Army Medical Services, has been elected an Honorary Freeman of the Society of Apothecaries of London "in recognition of his peculiar services to the State and the medical profession."

Medical Notes in Parliament.

Insurance.

THE first business taken by the House of Commons when it reassembled on June 20th was the votes for National Insurance, but Mr. C. Roberts, Chairman of the Joint Committee of Insurance Commissions, had a very small audience to hear his apologetic.

He began by saying that the Insurance Commissions had suffered more depletion of their staffs than older departments because fewer were over military age: 50 per cent. of the 1,424 men in the English Commission had been released for war service either through enlistments or by transference to other departments. The English Commission was now employing 1,331 women. The staffs of approved societies had also been depleted. The war had also prevented the Commissions from dealing administratively with a number of controversial questions. For instance, it had often been suggested in the course of the last twelve months that something ought to be done with respect to sanatorium treatment or with questions connected with the payment of doctors; but when the whole of the medical profession was being mobilized for the needs of the army it was out of the question to attempt to revise or reconsider the terms of the original agreement. Such questions must wait until peace restored normal conditions. The process of consolidating regulations hastily made at the beginning was proceeding, and so far as the English Commission was concerned was now practically complete, but it had been necessary to leave the Medical Benefit Regulations untouched.

Within the course of a few weeks a volume would be published containing the Act, orders, and regulations, and this publication he hoped would help to put the Act upon a proper basis. The chemists of England and Wales had reached an agreement with the Commissioners under which the very bad and unbusiness-like habit of discounting their bills had been abolished and prompt payment in full assured. In Ireland a belated and long overdue system of medical certification had come into force on January 1st. The grants for the Joint Commission—the four Commissions—and for the audit, showed a reduction, the figures being £7,700,000 in 1914, £7,195,000 in 1915, £6,300,000 in 1916-17; but it was not easy to compare this year's estimates with last year's. Two main changes had been made in the mode of keeping the accounts. The first was that sums paid to insurance companies for medical and sanatorium benefits and expenses connected therewith had, under the Act of 1911, to be paid at the beginning of the year; since the Act of 1913 payments could be made from time to time, and were, in fact, generally made month by month. Consequently, in the estimates for 1915-16, it was necessary only to provide one quarter's moneys, up to March 31st, 1916, whereas in the estimates for 1916-17 it was necessary to provide for the full financial year. The other main change was that now sums actually issued from time to time to the societies were charged against the vote. On balance, however, there was a substantial reduction in expenditure. The war itself had lessened expenditure; large transfer was going on from the class of employed contributors to the new armies, but this was offset by the new entrants, women and others, coming into employment. The State did not lessen its liability for benefits that would have been paid if the insured person had not gone into the army, except in reference to what he called doctors' half-crowns. There would be fewer half-crowns granted this year, and this was a real saving produced by the war. Further, with the rise in wages, the State would have to pay a lessened contribution on account of low-wage contributors. Under the abnormal conditions produced by the war, with greater opportunities for employment and high wages, the provision made for sickness and maternity benefits was in the case of men 8 per cent. above what was required, taking the average of all societies. On the other hand, though the shortage on the women's side was diminished, it had not been wiped out. This was due partly to the action of the House in 1911 in cutting down the actuaries' estimate. The result of the war on the finances of the Act would depend upon the balancing of forces. On the one hand, there might be benefit from improved physical training to set off against the strain of war service; there would be release of reserves by premature death; there was the opportunity of getting a higher rate of interest, and there was the present low rate of sickness. It was to be feared, however, that at a later stage, some years hence, there might be an upward curve of ill health due to the indirect effects of the war. On the whole, however, he considered that there was no real financial unsoundness which required special precautions to be taken. He hoped that the grant of £135,000 a year, representing the grant-in-aid of excessive sickness of women voted in 1914-15, would be continued, but apart from that it would be idle and unpatriotic to expect any further Government grants in the present condition of national finances. There had been very considerable progress in counties and county boroughs in tackling tuberculosis; with the money made available through the Insurance Act and by means of the Hobhouse grant the country had been covered with a network of hospitals, sanatoriums, and dispensaries, and, by voluntary effort and otherwise, tuberculosis schools and care committees had been set up. The comprehensive schemes of many counties and county boroughs were not yet complete, having been suspended by the war. The latest figures available were those for 1914. The applications for treatment that year increased by 6 per cent., persons treated by 17 per cent., cases treated in residential institutions by 69 per cent., and those treated in dispensaries by 232 per cent. Although full figures were not available, it was known that the percentage of cases treated in dispensaries had largely increased in 1915; the number of persons treated in residential institutions had dropped by a small percentage, but there were vacancies in institutions in different parts of the country. In Scotland there had been no difficulty in finding room for all the tuberculous soldiers reported, and in some of the institutions there were vacancies for the civil population. The number of cases of tuberculous soldiers referred to the Insurance Commissioners was 3,250. Arrangements had been made by means of a special grant to get priority of treatment for tuberculous soldiers, and all the cases reported had been offered treatment in residential institutions. Since the Insurance Act had been in force £2,800,000 had been found for the attack on tuberculosis by means of sanatorium benefit, and in 1916-17 the insurance committees would have from that source an income of £760,000, including a grant of £35,000 for tuberculous soldiers. In 1915 the sum paid to insured persons in respect of sickness benefit was £6,300,000, for maternity benefit £1,300,000, for disablement benefit £840,000, and the Commissioners had got a sum of £28,000,000 invested to meet the anticipated sickness which the present population would have to face ten, twenty, or thirty years hence.

Mr. Currie observed that the statement of Sir Gerald Ryan's Committee, "bankruptcy in the strict sense of the word cannot overtake the scheme," was not a very high compliment, and referred to the very severe strictures made on the administration of the Act by the Public Accounts Committee. Mr. J. Samuel, who also criticized the finances, demanded that

the Insurance Commissioners should prepare what insurance companies were bound to prepare every year for the Board of Trade—namely, a statement showing, first, the total income from all sources; secondly, the cost of administration; thirdly, the total amount paid in sickness, maternity, and disablement benefits. Mr. Rutherford contended that a considerable number of the societies were insolvent, and Mr. Booth argued that the expert committee would not have advised a raid on the sinking fund to the amount of £1,800,000 a year if a surplus could really be shown. He had held from the first that the financial provision made in respect of women was insufficient, and experience had proved this opinion to be correct. Mr. Booth also criticized the position with regard to sanatorium treatment, and alleged that the Insurance Commissioners sought to shift the responsibility from the insurance funds to the rates. The Financial Secretary to the Treasury deprecated discussion of the report of Sir Gerald Ryan's Committee; it had made certain recommendations which were now under consideration by the Treasury in consultation with the Insurance Commissioners. Mr. Dennis accused the Commissioners of making use of the fact that owing to tuberculosis now being a notifiable disease the public health authorities were under an obligation to provide hospital accommodation in order to evade their liabilities under the Insurance Act to provide sanatorium treatment. He asked whether it would be possible without legislation to arrange that when a man went into a sanatorium his sick benefit should accumulate. At present the money saved went into the General Purposes Fund, and the man, when he came out from a sanatorium, fell back into ill health because he was not able to earn wages sufficient to provide him with proper food and accommodation. Mr. Dennis also protested against the delay in paying doctors' accounts. Other members having criticized the manner in which sanatorium benefit was administered, Mr. Roberts, in a general reply, said that the obligation to building sanatoriums had not been imposed upon the Insurance Commissioners but upon the Local Government Board. The Act did not give every tuberculous person an unqualified right to sanatorium treatment in the sense of residential treatment; only those persons recommended by insurance committees had the right to claim such treatment.

Finance Bill.

Several important alterations in the Finance Bill were announced on June 21st. The clause imposing increased duties on licences for motor cars was withdrawn, and the Government announced its intention of making up the loss of prospective revenue by a tax of 6d. a gallon on petrol. This change, it was stated, was rendered possible by the fact that the Petrol Control Committee had instituted a central control of petrol stocks, which would be distributed under permits issued by the central authority. It was also announced that it is intended to raise the income a man may have, in order to claim the allowance for children, from £500 to £700. The method of graduating unearned incomes was altered. Clause 20 (Right of soldiers and sailors to pay reduced rates of income tax in respect of their pay) was so amended that while the rate upon a total income from all sources not exceeding £300 remains at 9d., as in the bill, incomes between £300 and £1,000, instead of being liable to a tax at the rate of 2s. 1d., would be subject to a graduated scale—1s. 3d. on incomes between £300 and £500, and 1s. 9d. on incomes between £500 and £1,000; on incomes between £1,000 and £1,500 the rate should be 2s. 3d. instead of 2s. 5d.; the rates upon incomes above £1,500 should remain as proposed in the bill. These reductions, it is estimated, will cost the country £200,000.

ALEXANDRIA is declared officially to be infected with plague, and it is unofficially reported that the disease prevails in Jaffa also.

CAPTAIN ARTHUR RYLAND CHAVASSE, R.A.M.C., only son of the late Sir Thomas Chavasse, left unsettled estate valued at £5,978.

The Hospital of the University of Pennsylvania, Philadelphia, has opened a clinic for the exclusive study of industrial and occupational diseases. Dr. Alfred Stengel, professor of medicine, is in charge.

SIGNOR LEONARDO BIANCHI, who is a member of the new Italian Ministry, no doubt as a representative of the party he leads—that of the Constitutional Democrats—is professor of psychiatry in the University of Naples and director of the University Clinic for Nervous and Mental Diseases. Although without portfolio, it is understood that he will devote himself to hygienic and social problems arising out of the war, especially the provision to be made for men who have lost limbs or have been otherwise disabled from following their civil occupations.

THE WAR.

THE SECOND GERMAN SURGICAL WAR CONGRESS.

ON April 26th, 1916, the second "Kriegschirurzentagung" was opened in Berlin by Professor v. Sehjerning, who reviewed briefly the main surgical events since the previous surgical congress held in Brussels last year. The fact that tetanus had been completely suppressed since then was, he said, a great triumph, as was also the adoption of a uniform treatment for fractures. The prevention of stiff joints by systematic early movements, and the more active surgical treatment of wounds of the skull and abdomen, especially in stationary warfare, also marked important advances. It was officially established that 86.6 per cent. of the soldiers in the field hospitals and special war hospitals, and 90.1 per cent. of the soldiers in military hospitals in Germany were discharged as fit for service; only 1.5 per cent. of the sick and wounded in the military hospitals in Germany had died. He also eulogized the services of the 6,800 nurses and sisters at the various stations on the lines of communication.

THE LOCALIZATION OF FOREIGN BODIES.

The allegation as to the use by the British of dum-dum bullets was repeated by Küttner, whose passion for accusing the British of employing this bullet does not seem to have been cooled by the numerous publications of other German surgeons, who have pointed out the impossibility of distinguishing between wounds inflicted by the dum-dum and the German regulation bullet. He also accused the Belgians of using a rifle bullet on to which a piece of wire had been soldered. Other speakers, discussing the fate of bullets left in the body, pointed out that, *ceteris paribus*, the French copper bullet was less harmful than bullets containing lead, as this was gradually absorbed by the body and excreted in the urine and saliva. Küttner insisted that bullets should be removed not only when they provoked sepsis or pain, or when they were quite superficial, but also when, by the help of the x rays, they could be located with precision, always provided that the operation was not dangerous in itself. Above all it was important that bullets should be removed from bone marrow. He had found that the extraction was frequently facilitated by the injection of iodipin into the track of the fistula; methyl violet and pyoktanin were also used. Grashey, in dealing with the localization of foreign bodies, said that there were more than 250 methods, which he proceeded to classify and criticize.

WOUNDS OF BRAIN AND NERVES.

Professor v. Eiselsberg expressed the opinion that tangential wounds of the skull should be operated upon as quickly as possible, provided a skilled surgeon were available. Large fragments of bone should be removed. When once meningitis had developed, its further progress could not be arrested. It was frequently basal, and lumbar puncture was of prognostic value only. The conditions least suitable for operation were those in which the bullet passed through the brain and escaped, and prolapse of the brain. When the bullet remained in the brain, but was superficial, or caused severe symptoms due to suppuration, operation was indicated. Abscess of the brain should be opened, but when the presence of a projectile within the skull caused no reaction, he preferred to wait. The filling up of gaps in the skull caused by projectiles should not be attempted early, as abscesses frequently developed long after the patient was apparently cured. Recent injuries of the cord seldom required immediate operative treatment. Adequate immobilization of the body and retention of a catheter in the bladder or the induction of a fistula of the bladder should be the first measures. Only in the case of compression fracture of the vertebral column was early operation indicated; otherwise it was best to wait eight to ten weeks. Incidentally he remarked that transverse lesions of the cord occurred not only when it was compressed, but also when there was serous meningitis. The prognosis of wounds of the cord was bad, and even when both sensory and motor symptoms improved, there was seldom any improvement in the bladder

symptoms. In 16 cases of complete paralysis, in which no definite improvement had occurred in the course of eight to twelve weeks, operation was followed by improvement in 8 cases and by none in 7. When, at the time of operation, serous meningitis was discovered, rapid improvement followed. Of 284 cases of open wounds of the brain, Steinthal said that he still had 37 under treatment; 89 had died, and 118 had returned to the colours. The causes of death in his fatal cases were abscess of the brain, encephalitis and meningitis.

In discussing the treatment of wounds of the nerves, M. Borchardt said that, from the surgical point of view, it was best to operate early. The earlier the operation, the less the amount of scar tissue encountered. The longer a nerve had been divided, the longer did it take to reunite; the sooner an operation was performed, the less were the contraction and atrophy of the muscles. But it was necessary to wait three to five months for the wound to be in a satisfactory state for operating. In many cases symptoms of total paralysis showed considerable improvement during this interval.

WOUNDS OF THE LIMBS, ABDOMEN AND CHEST.

Payr insisted on the advisability of reducing amputations to a minimum; the indications for amputation should be absolute, not merely prophylactic. Extension treatment should be adopted only after the patient had become afebrile. Early in the war secondary operations were necessary in 95 per cent., and they were still as frequent as 75 per cent. The importance of early operation in wounds of the abdomen was emphasized by Sauerbruch, whose experience with abdominal cases, operated on early, had been most gratifying. He considered the prognosis of intestinal fistula bad. In most cases the fistulae were multiple, and were often followed by severe disturbances of peristalsis due to adhesions. The prognosis of haemothorax was, on the other hand, good; when it persisted, he recommended puncture. The prognosis in empyema, of which he distinguished three forms, was worse. When the pleura was directly infected by the projectile, thoracotomy with drainage was indicated. Empyema resulting from suppuration eight to ten weeks after the development of haemothorax was less dangerous. The third form of empyema (caused by rupture of the lung and subsequent infection of the pleural cavity) was more serious, and required thoracotomy and extensive drainage. He recommended thoracoplastic operations when empyemata had left large cavities. Abscesses of the upper lobe of the lung should be opened from behind, whereas abscesses of the lower lobe should be treated on ordinary principles. In his opinion, it was rare for tuberculosis to develop in a lung as a consequence of a wound. Moritz had treated 532 cases of projectile wounds of the lungs, and only 28 patients had died. In 21 out of 511 cases the wound of the lung had been followed by peribronchitic inflammation. In 8 out of 615 cases gangrene of the lung had supervened. Returning to the subject of abdominal wounds, Læwen pointed out the high mortality of wounds of the kidney; the mortality in 28 such cases was 93 per cent.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON GEORGE MOORE JOHNSON, who met his death on H.M.S. *Defence* in the naval battle in the North Sea on May 31st, was born in 1879, and was the eldest son of Mr. G. W. M. Johnson of Childs' Bank and of Mrs. Johnson of Shortlands, Kent. He was educated at Charterhouse and at Magdalen College, Oxford, and the London Hospital, taking the degrees of M.A., and M.B., Ch.B. in 1908. He held the posts of house-physician and house-surgeon at the Radcliffe Infirmary, Oxford. In January, 1913, he went to Trinity, Newfoundland, and practised there till after the outbreak of war. He returned to England in January, 1915, and held the posts of assistant tuberculosis officer and school medical officer for the county of East Suffolk till he applied for a post as surgeon, R.N., when he was appointed to H.M.S. *Defence*. He leaves a widow, to whom we offer our sympathy. Such is the brief record of a man of whom his friends—and they were many—felt certain that he would have done good and distinguished service in his profession. Always fond of

sport and good at all games, he was a good shot and a keen and successful fisherman and boatman; indeed, in the course of his professional duties in Newfoundland he often went out in such weather that the fisherman would be anxiously awaiting his return. He had a very keen sense of his duty to his professional work, to which he applied abilities considerably above the average. Gifted with a superb body, he had a boundless store of energy, and lived his life with a zest and keenness it was a pleasure to watch, but beyond all was his extraordinary capacity of forming real friendships socially and professionally, and he will be sadly missed by a very wide circle.

ARMY.

Wounded.

Captain C. H. Maskew, R.A.M.C. (T.F.)

Captain J. F. H. Perras, Canadian Army Medical Corps.

Captain W. L. Shannon, Canadian Army Medical Corps.

PRISONERS OF WAR.

The *Pioneer Mail* of May 20th states that, among the invalided prisoners of war who were exchanged by the Turks, after the surrender of Kut, was Private Binod Bihari Chatterji, of the Bengal Ambulance Corps, who stated that all the other members of the detachment serving at Kut under General Townshend were well.

DEATHS AMONG SONS OF MEDICAL MEN.

Austen, Mark, Midshipman H.M.S. *Queen Mary*, killed in the action of May 31st, aged 16, was the son of Fleet Surgeon Thomas Austen, of H.M.S. *St. Vincent* (also engaged), and of Mrs. Austen, of 10, Palmeira Avenue, Brighton. After preparation for the Royal Navy he became a cadet captain at the Naval College, Osborne, and was appointed to his ship from Dartmouth College on January 1st, 1916. He had the qualities of a good cricketer.

Champneys, John Dalrymple, Lieutenant Leicestershire Regiment, who was officially reported "missing, believed wounded," in France on November 22nd, 1915, and who is now known to have been captured by the Germans and to have died of his wounds on the following day, aged 26, was the elder surviving son of Sir Francis H. Champneys, Bt., of Nutley, Sussex. He was educated at Rossall School, of which he was a foundation scholar, and matriculated at Balliol College, Oxford, taking honours in the Final School of Law. He was a good all-round athlete. At the beginning of the war he obtained a commission as second lieutenant, and was soon after appointed lieutenant. He was mortally wounded and captured while on patrol duty in France, died the following day, and was buried by the Germans at Monchy. His commanding officer writes: "He is a great loss to me, as he was an exceedingly useful and gallant officer, and has carried out many useful reconnaissances."

Elphick, William Roy, Second Lieutenant Indian Army, eldest son of the late Major H. W. Elphick, I.M.S., died of cholera at Bombay, on June 7th, aged 22. He got his commission on August 2nd, 1914, and was serving in the 108th Infantry, formerly the 8th Bombay Infantry.

Harvey, Ralph de Warene, Second Lieutenant Dorset Regiment, only surviving son of Harold Harvey, M.R.C.S., of Wyke Regis, Dorset, died of wounds on June 7th, aged 18. He got his commission on January 27th, 1915, after being educated at Weymouth College, where he was in the school eleven. His elder brother, Keith Harvey, serving in the Australian Force, was killed in France on April 25th last.

Page, Henry Rauthwell, of Winnipeg, and of Brough Fold, Kendal, Lieutenant Canadian Infantry, second son of the late David Page, M.D., killed in action on June 10th, aged 39.

Robertson, Thomas Arthur May, Sub-Lieutenant R.N., aged 21, was killed on H.M.S. *Queen Mary* in the North Sea action on May 31st. He was the third, but eldest, surviving son of Dr. James S. Robertson, of West Kensington, whose second son, Frank Henry May Robertson, came over with the 1st Canadian Contingent, and died in France on April 12th, 1915, at the age of 21.

MEDICAL STUDENT.

Aitchison, Andrew J., Second Lieutenant Highland Light Infantry, who died from wounds in France, was about 27 years of age, and was the youngest son of Mrs. Aitchison of Alexandria. He was studying medicine at the Glasgow University when he joined the colours over a year ago.

NOTES.

SIR DOUGLAS HAIG'S DISPATCH.

On June 15th the War Office published a dispatch, dated April 30th, from General Sir Douglas Haig, G.C.B., Commander-in-Chief of the British Forces in France, mentioning the names of 4,800 officers and men for gallant and distinguished conduct in the field. The list of those thus mentioned fills thirteen columns in the *Times* of June 16th. The following are the names of the medical officers included in the list. In addition, a large number of members of the various nursing services and of non-commissioned officers and men of the R.A.M.C., Regular and Territorial, are mentioned.

1st Life Guards.

Surgeon-Major R. M. Cowie.

2nd Life Guards.

Surgeon-Captain E. J. H. Luxmoore.

Army Medical Staff and Royal Army Medical Corps.

Surgeon-General R. H. S. Sawyer.

Colonels H. Carr, W. L. Gray, O. R. A. Julian, C. J. Macdonald, F. J. Morgan, F. R. Newland, H. I. Pocock, H. N. Thompson, S. Westcott, J. Wilson, R. W. Wright, A. L. F. Bate, A. Fullerton (temporary).

Lieutenant-Colonels F. C. Buswell, H. N. Dunn, J. D. Ferguson, J. V. Forrest, J. S. Galle, F. W. Hardy, H. C. R. Hime, E. W. Slayter, H. H. Thurston, E. A. Bourke, A. W. N. Bowen, O. W. A. Elsner, J. G. Gill, J. Grech, H. Hewatson, W. J. Taylor, A. C. Thompson, G. N. Stephen (temporary).

Majors H. H. A. Emerson, R. L. V. Foster, W. R. P. Goodwin, P. H. Henderson, D. O. Hyde, E. T. Potts, J. H. Brunsell, R. A. Bryden, T. S. Coates, R. F. M. Fawcett, A. O. H. Gray, R. C. Hallows, W. J. S. Harvey, A. J. Hull, T. C. L. Jones, W. D. O. Kelly, P. J. Marett, W. G. Maydon, A. C. Osburn, H. G. Pinches, A. M. Rose, H. G. Smeeth (S.R.), A. E. Webb-Johnson (temporary), C. F. White, J. H. R. Winder, B. F. Wingate, J. C. Webb (temporary).

Captains A. H. Heslop, W. B. Purdon, G. H. Dive, G. R. Edwards, L. T. Poole, H. C. D. Rankin, J. Rowe, W. C. Smales, A. D. Stirling, G. P. Taylor, J. L. Wood, W. A. Wright.

Captains, Special Reserve, W. J. Adie, W. M. Biden, S. M. F. Cesari (killed), D. B. Chiles-Evans, D. Dougal, T. I. Dun, W. R. Gardner, R. A. Greenwood, A. T. Logan, D. C. Macdonald, W. C. B. Meyer, W. A. Miller, R. Montgomery (killed), A. C. Perry, A. L. Robertson, H. E. Rose, H. N. Stafford, A. M. Thomson, P. Thornton.

Temporary Captains A. B. Cheves, H. J. Couchman, R. D. Fitzgerald, C. Y. Ford, J. H. Fletcher, A. C. Giles, A. S. Glynn, T. L. Gurney-Dixon, A. C. Hancock, C. Hardy, H. M. Hart-Smith, C. Kingston, E. C. Lindsay, N. P. L. Lumb, J. B. McCabe, D. J. McKee, E. L. Mackenzie, E. S. Marshall, D. C. Munro, H. Moore, J. W. Pell, E. L. Reid, H. H. Robinson, W. A. Sneath, J. L. Stewart, A. Stokes, W. A. Taylor, T. H. Whittington, C. M. Wilson, E. White, D. H. D. Wooderson, P. R. Woodhouse.

Temporary Lieutenants F. J. Blackley, W. E. Burrows, A. J. W. Cunningham, A. J. Cunningham, J. P. Musson, E. T. Pinkey, C. L. G. Powell, R. R. Scott, H. D. Smart, T. Strain.

Quartermaster and honorary Major: H. Spackman.

Quartermaster and honorary Lieutenants F. O. Chappell, E. W. J. Escott, J. D. Genese, J. W. Osborne, J. T. Packard, H. S. Polhill, W. C. Renton.

Dentists, Mr. A. C. Valadier, temporary Lieutenant R. L. O'Grady.

Royal Army Medical Corps (T.F.).

Colonels C. E. Harrison, Sir J. R. A. Clark, Bt.

Lieutenant-Colonels J. Clay (Northumberland C.C. Station), J. McKinnon (W. Riding F.A.), W. Peake (N. Midland C.C. Station), R. M. West (N. Midland F.A.), E. A. N. Wraith (N. Midland F.A.).

Surgeon-Major A. W. Cuff (W. Riding Brigade R.F.A.).

Majors E. F. Finch (W. Riding F.A.), A. C. F. Turner (N. Midland F.A.).

Captains H. M. Calder (London F.A.), W. Cowie (London F.A.), H. K. Dawson (London F.A.), N. A. Dore (London Sanitary Service), S. S. Greaves (W. Riding F.A.), S. J. C. Holden (W. Lancs. F.A.), M. T. Inglis (S.E.), A. E. Ironside (London F.A.), R. Jacobs (London Sanitary Service), G. G. Johnstone (London Sanitary Service), C. D. Law (S. Lancs. Regiment), J. P. Matthews (W. Riding F.A.), J. Miller (N. Midland F.A.), F. J. J. Ney (London Sanitary Service), H. G. Pearson (London Sanitary Service), J. E. Sandilands (London F.A.), A. Sutcliffe (Northumbrian C.C. Station).

Quartermaster and honorary Lieutenant S. Lyall (Northumbrian F.A.).

Canadian Army Medical Corps.

Lieutenant-Colonels G. La F. Foster, J. T. Fotheringham, R. P. Campbell.

Majors J. A. Amyott, A. C. Rankin, A. E. Snell.

Captains J. A. Crozier, H. B. Jeffs, J. S. Jenkins, G. C. Hale.

Indian Medical Service.

Major E. A. C. Matthews.

Captains R. L. Binning, W. B. Cullen, P. K. Gilroy, J. G. B. Shand.

Indian Subordinate Medical Department.

Assistant Surgeons W. E. Moody, E. J. Pell.

Sub-Assistant Surgeons Kunniyal Raman, Nabl Ahmed Sidiqui, Rafi-ud-din Khan.

HONOURS.

The Victoria Cross has been awarded to Captain John Alexander Sinton, M.B., I.M.S., for conspicuous bravery and devotion to duty. Although shot through both arms and through the side he refused to go to the hospital, and remained, as long as daylight lasted, attending to his duties under very heavy fire. In three previous actions Captain Sinton displayed the utmost bravery. Captain Sinton was a student at Queen's College, Belfast.

BRITISH RED CROSS SOCIETY.

The motor department recently dispatched nine cars and thirteen drivers to France, and one hundred other cars are ready to follow. Ten motor ambulances have been sent to the Russian Army in the Caucasus, and requests for special motors have been received from East Africa. There are fifteen launches at work on the Tigris, and, in addition, five

large and two small ambulance launches have recently been dispatched to Basra. The Aberdeen Branch has dispatched a motor launch to Malta to replace one sent from there to Mesopotamia.

PHYSICAL CLINIC FOR WOUNDED AND DISABLED SOLDIERS.

We have received the following communiqué: A physical clinique for the treatment of wounded and disabled officers is about to be opened at 126, Great Portland Street. The treatment, which will be entirely free of charge, will be under the direction of an honorary medical and surgical staff. In addition to the more familiar physical remedies (hot air and electrical baths, douches, massage, and manipulation) the clinic is furnished with whirlpool baths for the local treatment of stiff and disabled limbs and with a complete series of apparatus for mechanical treatment. The committee and medical staff invite members of the medical profession to view the clinic on Monday, Tuesday, and Wednesday, June 26th to 28th, and matrons and nurses on Thursday, June 29th, between 2.30 and 5 p.m. Cases will be received for treatment on and after Monday, July 3rd, at 2.30 p.m.

FEDERATED MALAY STATES HOSPITAL.

Thanks to the liberal financial support accorded by all classes of the community in the Federated Malay States, the Committee of Management of the Military Hospital established by these States at Blackmore End, Kimpton, Herts, has been able to increase the accommodation from 80 to 168 beds. Two new wards, each of 44 beds, similar in type to those of the Canadian Military Hospital at Orpington, Kent, have been erected in the grounds of the house kindly lent by Mrs. Vincent. The hospital is being equipped with an x-ray installation, the cost of which is being borne by Messrs. Edward Bonstead and Co., of Leadenhall Street, E.C., in conjunction with Messrs. Bonstead, Hampshire and Co., of the Federated Malay States. Captain G. D. Freer, R.A.M.C.(T.), formerly P.M.O., Selangor, is in charge of the hospital.

MEDICAL OFFICER WANTED.

3rd Line Field Ambulance, R.A.M.C.(T.F.)

Vacancy for a keen Medical Officer as Lieutenant (promotion to Captain in six months) in above unit, at present in England but drafts supplying; should ride or learn. Must sign for the war and imperial service obligation (foreign service if required). State age and experience.—Address, Commanding Officer, No. 1234, BRITISH MEDICAL JOURNAL Office, Strand.

England and Wales.

ROYAL COMMISSION ON UNIVERSITY EDUCATION IN WALES.

THE members of the Royal Commission on University Education in Wales have been paying a visit to Cardiff this week, where they have made themselves acquainted with the organization and equipment of the University College of South Wales and Monmouthshire and with the proposals for the establishment of a National Medical School for Wales, and the part which the Cardiff Hospital is prepared to take in that school. They propose to visit North Wales next week, and after the annual meeting of the North Wales Branch at the University College, Upper Bangor, on Tuesday, June 27th, a meeting of the profession will be held at 3 p.m. to hear an address by Sir William Osler, one of the members of the Commission, on the proposed National Medical School for Wales. It is expected that Mr. Thelwall Thomas, Professor of Regional Surgery in the University of Liverpool, and Lieutenant-Colonel Lynn Thomas, C.B., Consulting Surgeon to the Western Command and Surgeon to the Cardiff Hospital, will take part in the discussion on the subject. We hear that there is a proposal on foot to establish a separate University of Cardiff—a proposal which will call for very serious consideration, inasmuch as it seems extremely doubtful whether, with its present population, the policy of having two universities in the Principality is well advised. The proposal would no doubt come within the terms of reference of the Royal Commission, which is instructed, among other matters, to consider in what respects the present organization of university education in Wales can be improved.

NEW HOSPITAL SUPPLY DÉPÔT AT MANCHESTER.

The demand for surgical requisites and hospital garments for wounded soldiers and sailors has led to the establishment of the "Manchester War Hospital Supply Workrooms" at Dover House, opposite the University; they are under the superintendence of Lady Donner, with a committee of ladies, and under the auspices of the British Red

Cross Society and the Lancashire County War Comforts Association. The workers are all voluntary, and the rooms are open every day except Saturdays and Sundays. The work will supplement without interfering with the other work of the Red Cross Society or the County Association's working parties.

THE COTTAGE BENEFIT NURSING ASSOCIATION.

The Countess of Gainsborough presided at the annual meeting of this association, held on June 14th at Denison House, S.W. The objects of the society may be briefly stated as the training and supply of cottage nurses for country districts, the confederation of local associations working on the Holt-Ockley system, and the registration of cottage nurses, with needful supervision of their conduct and performance of duties. These nurses are selected from women (of good character, intelligence, and health), between 23 and 35, of the cottage class, and are trained during a four or six months' course in the theory and practical duties of sick nursing, and in some cases in maternity work. Their services are then placed at the disposal of the branch committees (of which there are some 150 in the country), and are available for tending sick persons in cottage homes, where they not only carry out the nursing instructions of the doctors, but give help in the household arrangements. To entitle to this benefit the patient has to pay a small annual subscription as well as a weekly fee during the nurse's residence, the amount of which is graded to meet the beneficiary's circumstances. The nurse is paid by the association, which reserves her certificate till she has proved her efficiency by four years' satisfactory service.

Miss B. M. Broadwood (the honorary secretary and director of the association) urged the importance of such service in sickness continuing to be available for cottagers in villages outside the range of district nurses. Nursing was a service rather than an independent profession. The doctors were the officers, and their instructions were to be carried out by the nurses. She trusted that the authorities of the College of Nursing might see their way to recognize in a separate list nurses of this special class, who did useful, if humble, work in the community, which could hardly fall within the scope of hospital-trained nurses. She was followed by Miss E. C. Joseph (Somerset), who outlined a scheme for the registration of nurses, based upon the standardization of efficiency; the recognition of different classes in the nursing service (for example, village nurses, sanatorium nurses, school nurses, children's sick nurses, and mental nurses, as well as fully trained hospital nurses), much as in the Teachers' Register were found elementary, secondary, university and special subject teachers, all hall-marked as efficient in their own class, though possessing different qualifications, certificates, and knowledge. She thought the college could do useful work by bringing within its fold nurses of all grades, with a recognized minimum standard of practical and theoretical efficiency, at the same time enabling a nurse to specialize, and to be recognized as "trained" in various branches of nursing. She recommended independent examinations distinct from those of the training schools, and that there should be at least two, the final admitting to qualification in various "schools," just as was the case at the universities with regard to final degree examinations. Specialities should be specially registered, so that the public might know for what the nurse was fitted and employ her accordingly. A short discussion followed.

RED CROSS WORK IN THE COUNTY OF LONDON.

The County of London Branch of the British Red Cross Society has issued a report on its work during the first seventeen months of war. A large part of its eighty pages is concerned with the eighteen Voluntary Aid Detachment hospitals which the branch has established in the county area. (Since December, 1915, the end of the period covered by the report, we believe that the number has grown to twenty-three.) The largest of these hospitals is that handed over to the Kensington Division of the branch by the trustees of the Weir Hospital Charity; it has 150 beds, and the report claims for it that it is one of the best hospitals of its kind in England. The other hospitals are mostly private houses which have been lent for the purpose, and accommodate each from thirty to fifty patients. Up to the end of 1915 the admissions to the hospitals numbered close upon 3,000. Other forms

of-work undertaken by the branch have included general service in military hospitals and the forming of squads of Red Cross men to assist in the transport of the injured across London; the report records with pride that among the injured thus assisted was His Majesty the King. The only grudging word in the report is a reference to the disadvantage under which a County of London branch must labour owing to the comparative lack of local patriotism in the youngest of the counties; but with twenty-one divisions all keenly at work, and Voluntary Aid Detachments at a strength of above 7,000, not to speak of 350 members serving abroad, even the conglomerate boroughs which make up London ought to feel that they have here something in common and to be proud of.

Scotland.

DR. ROBERT A. FLEMING has been appointed on the staff of officers of the King's Body Guard for Scotland (Royal Company of Archers) vice Dr. William Allan Jamieson, deceased.

At a meeting of the Aberdeen University Court on June 13th Principal Sir George Adam Smith announced that the University had accepted an offer of Sir J. R. D. McGrigor to convey to the University a painting of the quadrangle of Marischal College as it was before the recent additions, and including the obelisk which used to stand there before it was removed to the Duthie Park. The Principal said they accepted it as a memorial of Sir James McGrigor, one of the most illustrious medical graduates of the University. The painting is by the late Mr. J. Giles, a well known Aberdeen artist, and is dated 1861. McGrigor was chief of Wellington's medical staff in the Peninsular War. An account of him appeared in the *BRITISH MEDICAL JOURNAL* of July 25th, 1914. McGrigor was Director-General from 1815 to 1851, and did much for the reform of the medical service of the army. He was described by Wellington as "one of the most industrious, able, and successful public servants I have ever met with."

THE SCOTTISH RED CROSS BRANCH.

A deputation, headed by Major David Wallace, C.M.G., R.A.M.C.(T.), which at the request of the Executive of the Scottish Red Cross Branch recently paid a visit to France, has reported very favourably on the work of the Scottish units. At Rouen they noted great improvements in the accommodation of the staff, and the general air of comfort and amenity of the grounds and buildings of the Scottish hospital, and found the Scottish convoy was undertaking all the motor ambulance work in the centre. They inspected the personnel and cars, which number over one hundred, and were satisfied with the arrangements for the maintenance and repair of vehicles. They were informed by the D.D.M.S. that the work of the convoy was highly appreciated. In Paris they visited the Hôpital de l'Ecosse, carried on by the branch since September, 1915. They found that it was working in a most satisfactory manner, and was highly appreciated by the French military authorities. A Scottish convoy of thirty ambulances has been working on the French front since the beginning of this year, and has earned golden opinions from the Minister of War. The branch has recently presented an x-ray ambulance car to the French, another to the Russians, and three for the use of our own troops. Each has a complete x-ray apparatus and a portable tent, and is designed for use immediately behind the firing line.

Ireland.

A MIDWIVES BILL FOR IRELAND.

At a special meeting of the Royal College of Physicians of Ireland, held on Friday, June 16th, the President and Fellows unanimously adopted a resolution urging on the Government the pressing necessity which exists for the passing of a Midwives Bill for Ireland, which is now the only part of the United Kingdom without legislative control of midwives. Such a bill is needed to protect lying-in women, to control infant mortality, and to enable

Irish trained midwives to take their proper place in the ranks of the registered midwives of the United Kingdom. The Parliamentary Committee of the College was empowered to take such steps as might be deemed necessary to help forward such legislation.

Sydney.

THE UNIVERSITIES AND THE WAR.

At a recent meeting of the Senate of the University of Sydney a communication was received from the University of Queensland in regard to the award of university scholarships and medals to children of alien parentage during the continuance of the war, and asking for co-operation between the universities to secure the objects aimed at. It was resolved:

That, in the opinion of the Senate, it is not desirable that public endowments in the form of public exhibitions, scholarships, bursaries, medals, or prizes should be awarded to persons of enemy parentage who are unable to produce satisfactory proof of naturalization with complete release from their obligations of allegiance to the country of their birth or descent.

THE DEPARTMENT OF PUBLIC INSTRUCTION AND THE NEW SOUTH WALES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

The Political Labour League has been holding its annual conference in Sydney, and its proceedings have been marked by some extraordinary speeches and votes. At one of the sessions a letter was received from the Minister of Education, Mr. Griffith, asking that the conference should be given an opportunity of discussing the question of the British Medical Association and the medical treatment of school children. A member obtained a suspension of the standing orders to move the following:

That this conference extends its unstinted support to the Government in resisting the attempts of the British Medical Association to prevent the medical treatment of defective school children by their threats of the boycott of those members accepting appointments for that purpose.

Permission was given to Mr. Griffith to speak on the matter. He stated that, as the result of an inspection by a travelling clinic, the parents of 57,000 school children were notified that their children were physically defective. After twelve months, 40,000 of these children were still without treatment. If not attended to, the defects would become permanent. In most cases the lack of treatment was due to the want of means to pay the heavy fees charged by the medical practitioners. In the country it was worse because often treatment could not be obtained. Money for a travelling clinic was voted by Parliament, and medical men were advertised for. The British Medical Association had said it would give permission to its members to do the work, provided that the parents of the children certified that they were not able to pay for treatment. He (Mr. Griffith) resented this as putting a brand of pauperism on certain children. Later on the British Medical Association had decided to "black-ball" those doctors who did the work. As a response he had obtained permission to bring in legislation to provide that any registered medical practitioner who refused to meet the Government doctors in consultation would lose his own registration. It was of enormous importance to give the children a chance in life. It had been said that the State could not afford the money, but he replied that the country could not afford to have 40,000 children growing up with physical defects. He would rather send to China for medical men than allow it. It had been stated that the British Medical Association was a kind of trades union, and that it had a sneaking regard for the unionists. It was not, however, a trade union, but a medical combine. The fight against the British Medical Association was going to be a bitter one, and he hoped for the unanimous support of the unionists and leagues.

The motion was carried unanimously.

Mr. Griffith reiterated in this speech a statement which does not accurately express the position taken up by the profession. The British Medical Association has never refused to treat these defective children, but insists that the

means for their treatment are already in existence, and that there is no necessity to appoint special doctors for this purpose.

THE ROYAL PRINCE ALFRED HOSPITAL AND THE WAR.

At the recent annual meeting of the subscribers of the Royal Prince Alfred Hospital, Sydney, the Chairman, Sir Thomas Anderson Stuart, referred to the effect of the war on the efficiency of the hospital. When war was declared the board determined that it was its duty to keep the positions of those members of the staff who desired to serve the empire with the military forces vacant until their return. Of the 40 honorary medical officers, there were 13 on active service; of the resident medical officers, 20 were at the front; of the nursing staff, a like number had joined the Expeditionary Forces; and of the members of the lay staff, 22 were under arms. He referred in sympathetic terms to the death of Dr. Verge in Egypt; his name appeared on the roll of honour placed in the main hall of the hospital by the kindness of Mr. S. Hordern, the new honorary treasurer. The board had also determined not to countenance permanent appointments to the honorary staff during the currency of the war, so that when the war was over and the men came back they would not find places for which they would have liked to have been candidates permanently filled in their absence.

The treatment of patients in the venereal clinics was begun on January 11th, 1915; unfortunately, it had been an overwhelming success in regard to numbers, but, fortunately, it had been an overwhelming success in regard to results. The number of persons, male and female, treated at the clinic was close on 2,300 in the past year. These patients overran the institution, and the doors had to be closed in order to limit their number. This state of things was a disgrace and a shame to Sydney, and a perpetual menace to its people. The chairman stated that he did not wonder that there were 500 soldiers constantly in the venereal compound connected with the military camp. He pleaded for a greater number of venereal night clinics connected with the public hospitals. Eighteen additional beds had been provided for children between the ages of 3 and 8 years suffering from congenital and other forms of syphilis. Regarding the question from the financial aspect, he emphasized the waste of keeping 500 men in idleness and worse in the compound. When these men were discharged from the service, as often happened, the cost of their training and equipment was thrown away.

VITAL STATISTICS.

According to the State Government statistician's report on the vital statistics of Sydney for the year 1915, the estimated population of the metropolitan area was 763,000 on December 31st; the city contained 104,200 and the suburbs 658,800. The increase during the year was 10,500. The city population decreased by 6,500, but the suburban population increased by 17,000. The number of marriages was 10,122 (the largest number yet recorded), corresponding to a rate of 13.36 per 1,000 of the population. The births registered during the year numbered 20,871, equivalent to a rate of 27.54 per 1,000 of the population. The number of births is the highest ever recorded in the metropolis, but the rate, which is 2.5 per cent. below the average of the preceding five years, is the lowest since 1910. The deaths numbered 8,189 (4,461 males and 3,728 females), equal to a rate of 10.81 per 1,000 of the population. The rate is equal to the average of the past five years. An exceptional mortality was experienced in November and December among infants, which materially affected the year's rate, which in other months was remarkably low.

THE Kansas State Board is endeavouring to get the State Universities to co-operate in an effort to induce the Government to establish a health experiment and research laboratory in connexion with each university school of medicine under the United States Public Health Service.

ON June 16th the President of the French Republic accompanied by Madame Poincaré and the Minister of Labour, M. Albert Métin, visited an exposition of the work of maimed soldiers in the Galliera Museum. M. Poincaré expressed his admiration of the ingenuity and artistic sense shown by the men.

Correspondence.

MEDICAL OFFICERS, SPECIAL RESERVE AND TERRITORIAL.

SIR,—May I draw the attention of your readers to the paragraph on page 144 of the SUPPLEMENT to your issue of June 17th which reads:

As every doctor coming under this heading B [that is, those who do not enrol], whether refused exemption or exempted only temporarily, will have been brought in under the compulsory provisions of the Acts, and as (by not enrolling) he has not availed himself of the privileges offered under A.C.I. 435, his term of R.A.M.C. service will be for the whole period of the war, and on the "ordinary" rates of pay, without any of the special arrangements as to pay or twelve months periods or otherwise that have been accorded to doctors who offer themselves for service in the R.A.M.C. in this war.

May I point out that:

1. Regular, Territorial, and Special Reserve medical officers are all paid the "ordinary" rate of pay, and that they serve for the full period of the war.

2. It therefore follows that in condemning those medical practitioners who do not enrol, to the "ordinary" rates of pay and service for the "full period of the war," you are condemning them to precisely the same term of service as has been accepted by the Regular, T.F., and Special Reserve officers—in other words, Sir, the T.F. medical officers who did their bit during peace time, and will continue to do so for the "full period of the war," are to be classed in the same category, financially and morally, as the man who has never done anything, and apparently doesn't wish to do it.

Further comment is unnecessary.—I am, etc.,

A SATURDAY AFTERNOON (R.A.M.C.T.F.) SOLDIER.
June 17th.

*** Judging from the terms of this letter, it does not appear that the writer fully appreciates the significance of the fact that the paragraph he quotes occurs in an official War Office memorandum. We altogether agree with what we understand to be the intention with which the letter is written, for we think that the officers of the Special Reserve and the Territorial Force are being shabbily treated by the State.

"THE SOLDIER'S HEART."

SIR,—When I wound up the discussion on "the Soldier's Heart" I did not anticipate that I should have to deal with very irrelevant letters written under the same title. It should be the duty and privilege of an editor to see that his correspondents not only stick to their text but show some knowledge of the subject on which they write. The late John Edgar, D.D., after listening to a sermon by one of his students, said, "Sir, one might think that your text had got the typhus fever, you kept at such a respectable distance from it." This caustic criticism was not more applicable to the sermon than to the letters of my critics.

The letter of Dr. Knox is merely a testimonial, in my opinion a very unnecessary one, to rehabilitate the professional ability—which was never assailed—of Dr. Florence Stoney. She may well exclaim, Save me from my friends! He incidentally says that I "should read more extensively and accurately." What are his grounds for turning my criticism on myself? Simply that I did not read a paper by Dr. Stoney on the x-ray treatment of Graves's disease; if I had, I do not know that I should have discovered anything new. Such treatment dates a long time prior to 1912, and I might claim to have been among the first who used the x rays in the treatment of exophthalmic goitre. I do not know who first used them in the treatment of this disease, and I do not care; there is nothing original in the idea: it is merely an extension of Keen's treatment of the spleen to the thyroid gland. I may candidly tell Dr. Knox, and I am pleased to say so, that I do not read a tithe of current medical literature, but if I were dealing, or attempting to deal, like Dr. Florence Stoney, with a question of priority I should take care to know the facts.

I would like to say to Dr. Lyon Smith, in the language of Byron, "A man must serve a time to every trade: critics are ready made." With his reference to my "remarkable sentence" I should like to turn him over to the tender mercies of Dr. Mercier. He says that I point

"out the association between the soldier's heart and trouble in the ductless glands." When did I do this? I thought that I had associated the irritable heart so commonly met with in soldiers of the present day with overaction of the thyroid. He complains that I "do not throw any light upon the factors which cause these glands to misbehave." I thought that I had, but at any rate I am sorry that I have not enlightened Dr. Smith. Even now I would try to do so if I thought that this anxious inquirer really sought information. I never said that he was to "draw the line rigidly at these two bacteria" of diphtheria and pneumonia respecting the effects of toxins on the adrenalin function. Let us have, by all means, the specific actions of the "hundreds of other bacterial ferments." The more knowledge we get the better, but let it be knowledge and not random talk about such ferments as have no more to do with the causation of the irritable heart than the flowers which bloom in the spring. As my quotation of Sir Isaac Newton's dictum does not seem to have made any impression on Dr. Lyon Smith I will give him a Latin one, which he will find, along with another by Sir William Hamilton, in *The Principles of General Physiology* by Professor W. M. Bayliss. "*Entia non sunt multiplicanda praeter necessitatem.*" Dr. Smith says that "it would be interesting to know the precise laboratory methods which Sir James Barr recommends for this important eliminative process." This may appear very smart to Dr. Lyon Smith, but I hope not to others. I should have thought that it would not require a laboratory method to eliminate a process which was not in action. At present I only wish to eliminate this belated critic.

My dental friend, Mr. J. G. Turner, evidently thinks that he has got his teeth into the subject of "the soldier's heart." I shall now try to release the matter from his incisive grip. I would remind him that the usual septic organisms which are found in the mouth and nasopharynx and their effects are well known, but the symptoms to which they give rise, when they or their toxins find their way into the circulation, are not those of "the soldier's heart." "Practically every soldier is the subject of some degree of dental or nasopharyngeal sepsis." Why limit the sepsis to the unfortunate soldiers? If he examine the mouths of all the dentists and doctors in London, how many does he expect to find aseptic, and how many of the examinees does he expect to find suffering from "the soldier's heart"? Personally I am always proclaiming a raid on oral sepsis, but I see much which appears perfectly harmless even when the breath stinks. So long as the organisms remain on the surface they can be disregarded, though in the interests of cleanliness, of dentistry, and of outsiders this is not advisable. It is quite true that three gentlemen discovered a harmless organism, which they thought was the cause of "the soldier's heart," but I think I scotched that idea last November; at any rate, its propounders have not come forth with any attempt at proof. Moreover, you cannot cure the irritable heart by eradicating the sepsis; there are many cases of "the soldier's heart" without any evidence of sepsis or septic absorption, and the symptoms continue after the dentist has worked his sweet will.

On the other hand, "the soldier's heart" is invariably associated with a more or less enlarged and overacting thyroid; the symptoms of "the soldier's heart," pure and simple, are those of hyperthyroidism and of nothing else. The causes of the thyroid taking on excessive action is beyond my present object. Of course there are many cases of tachycardia without any excessive function of the thyroid, and we should not confuse merely rapid action of the heart, however frequent, with hyperthyroidism, which presents many other definite symptoms. Perhaps Sir William Hamilton's dictum will do Mr. Turner good. "Neither more, nor more onerous, causes are to be assumed than are necessary to account for the phenomenon."—I am, etc.,

Liverpool, June 17th.

JAMES BARR.

ON MALUNITED AND UNUNITED FRACTURES.

SIR,—Lieutenant-Colonel Robert Jones, in his paper on this subject published in the *JOURNAL* of June 10th, states that for various reasons a certain proportion of fractures take longer to unite than others, and says that he prefers not to waste time on such cases as tabes, syphilis, and

acute diseases, but to go to what is, in his opinion, the root of the matter in the average case—namely, inefficient reduction, compression by splint and bandage, etc. I maintain that first and foremost, provided reasonable care is shown in practical details of alignment, etc., the root cause of non-union is the absence of lime salts, partly due to shock, partly to failure to select a diet containing such salts, and partly to the absence of medical treatment which might be carried out prophylactically in every case of fracture from the start. Why does the poultry farmer give grit to his hens? In order to make strong egg shell. As to treatment, Lieutenant-Colonel Jones says: "If a case of delayed union is first seen in the seventh or eighth week we need do no more than make quite sure of good alignment, etc. *Nature will do the rest.*" Will she? My hypothesis as outlined above suggests she may sometimes but not nearly always. Why not ally medicine with surgery, and try routine treatment of all fractures with the chemical constituents of bone; no suggestion as to suitable diet is made. I suggest plenty of milk, for it is rich in lime ($1\frac{1}{2}$ gram per litre, some as citrate and some as phosphate), eggs for the iron and phosphorus they contain, all cereals, porridge, and plenty of vegetables such as asparagus, radishes, turnips which contain plenty of lime salts. Is it not well known to farmers that turnips are the best thing to feed weak-boned animals on? The organic constituent of bone may be derived from meat, but it can be obtained from fish; at any rate plenty of milk suggests plenty of lime salts at disposal of the patient's economies.

The treatment by percussing and damming referred to by Lieutenant-Colonel Jones is, I take it, designed to stimulate and consolidate the indolent callus, to convert it, as he says, into an osteogenetic factory, so that bone may be generated. I suggest that this stimulating and consolidating action can be produced at any time by giving lime salts, and at any stage of non-union. I have carried this out successfully nine months after the accident in a case of fractured femur which had been plated and the ends rubbed together at a hospital with no success. I used it also in a fractured metacarpal bone with weak union at the end of two months; in a week it was strong, and the old callus levelled down and tendon movement freed. In an old fractured patella, twice wired, the second time with good union apparently, but much lumpy old callus, which prevented free movement, the exhibition nine months after the accident of lime salts acted so well that the patient could easily go back to work after a week's treatment. I treated a complete fracture of the tibia through the tibial tubercle of a man run over by a taxicab. The case was x-rayed at a hospital which had no bed free; at the end of ten days I took the splint off for massage and found hardly any evidence of union starting at all; the leg sagged at the slightest movement. I then amused the patient by telling him to watch the result at the end of four days' treatment with lime salts; on removing the splint, callus was evident and becoming hard, and there was no more sagging at the seat of fracture. This patient, although 70 years of age, got about on crutches at the end of five weeks and with a stick at the end of six, when he wished to go back to work. I have treated an old shrapnel wound of the wrist with exuberant callus (nine months in hospital), and in a few weeks movements have become nearly normal—before there were none.

This diet idea, of course, is not new, but is strangely absent from the usual textbooks; I have met with it only in Stimson's, where a good tonic—preferably one containing lime salts—is said to be useful. I say give syrup. ferri phos. co., which contains iron phosphoric acid, calcium carbonate, potassium bicarbonate, and sodium phosphate, which comes as near the constituents of bone as can be; 1 to 2 drachms a day in tablets should be given from the start in every case of fracture. The pathology of it is, I take it, that the natural setting of bone by calcification of the granulation tissue must be helped by plenty of lime to form good strong callus, and this takes usually one to four weeks, the osteoclastic action softens the ends of the fracture, and the callus must be well limed before the osteoplastic cells can start to work and make bone.

I conclude with the prescription of plenty of milk, eggs, and generous diet, and the vegetables named above, coupled

with tablets of syrup. ferri phos. co. from the start of the case, presuming, of course, the best possible surgical skill.—I am, etc.,

Southwark, June 10th.

REGINALD LARKIN, M.D.Lond.,
M.R.C.S.Eng., L.R.C.P.Lond.

THE RATIONALE AND PRACTICE OF CHEMIO-THERAPY.

SIR,—Leaving aside the fact that prejudice pervades the editorial on "The Rationale and Practice of Chemiotherapy," it is so full of misstatements that I must ask you to be so kind as to publish the following:

1. The compounds intramine and ferrivine were practically unknown to chemists. At the commencement of my work I sought the assistance of some of the leading chemists in this country, and even wrote out the formula of intramine for them, but none were familiar with it. It was purely by accident that I discovered Hofmann's work after I had succeeded in manufacturing the sulphur compound, and I doubt very much whether the phrase "long known to the chemists" would have found place in your columns if I had not in my first paper mentioned Hofmann's work. I am so far unfamiliar with any written description concerning the preparation of the ferric salt of sulphonic acid.

2. I particularly alluded to a case of interstitial keratitis which had proved refractory to intramine for two reasons—(a) to show the influence one drug has in assisting the action of another; (b) to bring to light the far from uniform results obtained by salvarsan in glossitis, as I had shown a case, which healed up at once with intramine, having proved refractory to salvarsan.

3. So far as ferrivine is concerned, it is obvious why the results obtained with it are not uniform, and one of my objects in reading the papers was to seek assistance to remedy the defects, needless to say without success.

4. Professor Bayliss was the only speaker who criticized my theoretical views. It is true that one other speaker associated himself with Professor Bayliss. Professor Bayliss was ignorant of my previous work, and admitted that he had probably misunderstood what I had said, as my paper was only an abstract. To show how true this is, I will review the remarks made by the speaker in question.

"It is unfortunate that oxidation and reduction processes should have been selected as the basis for the theory of chemotherapy." That such a statement should have been made is more than unfortunate. The light thrown on so-called scientific methods pursued by many shows the deplorable state of scientific research. Do our foremost scientists select the basis on which they found their theories? If so, I must plead guilty to entirely wrong methods. I did not select my basis; indeed, it was forced upon me by plain deductions from observed facts. A point on which I should like to lay special stress is this: however unfortunate my selection, it enabled me to produce at the first attempt a drug in some respects superior to those produced by Ehrlich in several hundred attempts, in spite of his having the services of the very best German chemists at his command.

"Of all processes taking place in the living body they are those the mechanism of which is most obscure." Doubtless it is unfortunate to disperse any of this obscurity, or even to endeavour to do so. However obscure these processes may be there is no doubt of their occurrence, and there is no doubt that they are the most important processes which take place in the living body. Must we therefore rule out of consideration oxidation and reduction processes in the body simply because their mechanism is obscure?

Maybe the sense in which the term "oxidase-reducase" system is used is not clear. It could not have been so if it gave the impression that one system should simultaneously be both oxidizing and reducing in its action on a given body. I desired to convey the impression that such a system was ready to act catalytically as either an oxidizer or a reducer, or to activate oxidizing or reducing reactions. As I have pointed out, the *Leucocytozoon syphilidis* has some phases which may be put out of action more quickly by oxidation, and others more quickly by reduction; it is therefore clear that simultaneous oxidation and reduction of the same body is not even desired or expected, even if it were possible.

"... but as adsorption had been shown to depend on surface, an increase in size of the molecules would tend to diminish their adsorptive power."

Professor Bayliss evidently assumes from this that the amount of protein in the serum is constant, and that aggregation of the smaller particles takes place. If this were the case, the specific surface—that is, the total surface—would obviously be less, but from ultra-microscopic examination I have proved that the protein particles in a syphilitic serum are greater in size and number than those in a normal serum. Unfortunately the ultra-microscopic method is not always available, so I proved the point in other ways. Syphilitic serums contain more protein than normal serums, more adsorbed amino-groups and more adsorbed electrolytes—note the readiness with which syphilitic serums clot. My new test for syphilis with glacial acetic acid lanthanum sulphate depends entirely upon the differences just mentioned.

Furthermore, the larger the molecule the greater the number of small molecules it will form when it breaks down, an action which follows the administration of the chemiotherapeutic remedies, hence their adsorptive capacity would be increased.

There is the further remark that "adsorption depended on active oxygen." I was naturally only referring to adsorption *in corpore*, not to adsorption in general, as Professor Bayliss probably thought, otherwise he would not have mentioned the adsorption of carbon dioxide by charcoal—an example far from apropos of the subject matter.

For the adsorption between the lipid-globulin molecules of the serum on the one hand and those of the parasite on the other, the presence of active oxygen is absolutely necessary, for without active oxygen the adsorptive power of the former would be diminished, since any interference with the active oxygen renders such molecules less emulsoid, and may even cause precipitation. In my book, *Links in a Chain of Research on Syphilis*, many other proofs are given for my statement that adsorption *in corpore* is dependent on active oxygen. Indeed, if my work be carefully studied it will be found that all my deductions have been built upon an experimental basis, and that none are contradictory or contrary to observed facts.

Before the meeting was held I am sure it was general opinion that arsenic was essential and that it killed the parasites directly, points which were deduced by Ehrlich from pure theory and built up on an unsound and illogical experimental basis. My object was to show that the rationale of Ehrlich's chemotherapy was totally incorrect, that arsenic was not essential, that the death of the *Spirochaeta pallida* was not the main point to aim at, as it is not the sole cause of the disease, and that sulphur and iron compounds could be prepared which had an anti-syphilitic action—an action which would be greatly enhanced by co-operation to improve the compounds so far prepared. Iron and sulphur are non-toxic elements, they are mutually complementary, and their use stimulates and stimulates processes that are naturally occurring in the body. Hence I think I may say that my object was attained, with the one exception of succeeding in obtaining any co-operation.

The last sentence in the editorial contains the following words: "Any reasonably safe therapeutic procedure will in this country secure an unbiased trial, especially if there is sound experimental evidence in its favour." This statement surely should not have been made, for it should be assumed that any trial would be unbiased. The mere making of the statement inevitably leads to the belief that there exists in the writer's mind a trace of suspicion that the trial may not have been entirely free from bias, a view held by the majority who are interested in this subject. So far as the sound experimental evidence is concerned, I think the cases I exhibited and the 400 odd injections I have given prove beyond doubt—namely, that ferrivine and intramine have a powerful anti-syphilitic action, and that the sulphur compound is complementary to the use of any metallic compound, and therefore should be employed in every case of syphilis.—I am, etc.,

London, W., June 15th.

J. E. R. McDONAGH.

FEES OF LOCUMTENENTS.

SIR,—I trust medical agents are not to be allowed to dictate rates of remuneration for the profession. We do not want the old sweated "locumtenent" back again, but

men whom we can trust and who deserve to be properly treated. The Clyde "rollers" make £20 a week!—I am, etc.,

Edinburgh, June 17th.

JAMES CAMERON, M.D.

THE DR. JAMES B. BIRD MEMORIAL FUND.

DR. JAMES B. BIRD, of Carlisle, was universally respected by his colleagues and highly esteemed by the people among whom he worked; he died of influenza last April, at the age of 47, and had been unable to make due provision for his family. A committee was formed in Carlisle to raise a memorial fund for the education of his children, and we are informed that it now amounts to £1,623 ls. 6d. At a recent meeting of the executive committee it was decided to close the fund at the end of the present month, and three trustees were appointed to administer it. Further subscriptions should be sent at once to the Honorary Treasurer, Mr. James Nelson, Bank of Liverpool, Limited, Carlisle. The following subscriptions from members of the profession have been received since the list published in our columns on May 20th:

	£ s. d.		£ s. d.
Dr. A. C. Burrows, Carlisle	5 5 0	Dr. J. R. Burnett, Keswick	1 1 0
Dr. Helm, Carlisle	5 5 0	Dr. John Brown, Blackpool	0 10 6
Dr. Farquharson, Carlisle	5 5 0	Dr. T. C. Guthrie, Tunbridge Wells	10 10 0
Dr. R. Fawcitt, Broughton-in-Furness	2 2 0	Dr. Shephard-Walwyn, Wetheral, Cumberland	5 5 0
Dr. C. W. Graham, Carlisle	3 3 0	Dr. C. T. Street, Crosby-on-Eden	2 2 0
Dr. Macdonald, Carlisle	3 3 0	Major Butterworth, Carlisle	2 2 0
Dr. H. J. Robinson, Kirkoswald	1 1 0	Dr. Rufus E. Evans, Newcastleton	2 2 0
Dr. Edwards, Carlisle	3 3 0	Dr. G. B. Muriel, Whitehaven	3 3 0
Dr. Logan, Ecclefechan	4 4 0	Dr. J. Barclay, Wetheral	2 2 0
Dr. Alfred Cox, London	1 1 0	Dr. Donald, Carlisle	5 5 0
V.P.R.C.S.E.	10 10 0	Dr. C. Crawford-Aitken, Carlisle	5 5 0
Dr. Doughty, Dalston, Cumberland	3 3 0	Lieut. P. A. Bennet, Clark, R.A.M.C.	2 2 0
Mr. C. Balfour Paul, Carlisle	8 8 0	Lieut. Walter Mercer, R.A.M.C.	2 2 0
Dr. Edington, Penrith	2 2 0		
Dr. Dodgson, Southwaite	2 2 0		

The Services.

THE AUXILIARY R.A.M.C. FUNDS.

THE Provisional Committee appointed at the meeting at the Royal Army Medical College on June 1st to consider and report on the steps which should be taken to establish a fund for the benefit of the auxiliary branches of the R.A.M.C., will present a scheme at the meeting to be held at the Royal Army Medical College on Monday next, at 2.45 p.m., under the chairmanship of the Director-General.

The committee will recommend the formation of two independent funds for the auxiliary R.A.M.C. Forces, one a benevolent fund for the orphans of officers and the other a relief fund for the widows and orphans of the rank and file. It is recommended that the funds should embrace the three auxiliary branches of the corps, and that both funds should be administered by the same committee, which should be representative of the three auxiliary branches—namely, Special Reserve, Territorials, and those holding temporary appointments in the R.A.M.C.

The scheme of the committee seems to us, as we have indicated elsewhere, so defective that we hope it may be withdrawn and a wider reference given by the meeting on Monday to a committee strengthened by the inclusion of more men who have an intimate personal acquaintance with the hardships and difficulties suffered by medical men engaged in civil practice, and by the addition of representatives of existing medical funds and organizations. We therefore refrain from publishing further details of the provisional scheme.

The Provisional Committee adopted the following resolution at its meeting on June 15th:

To recommend the general meeting to appoint a committee to report to a further meeting on the possibility of the establishment of a loan fund to help medical officers of the auxiliary forces who are in temporary difficulties on returning to their civil practices.

EXCHANGE.

CAPTAIN 2nd Line Field Ambulance (T.F.) wishes an exchange with M.O. attached to Base Hospital abroad, or Ambulance Train.—Address, No. 240, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

The University and the War.—At a meeting of the Senate on May 24th a letter was read containing the King's congratulations upon the important part the University was taking in connexion with the war, not only in actual military service but in science and research, and expressing his sympathy with the losses sustained.

Recognition of Teachers.—The following were recognized as teachers at the institutions and in the subjects indicated:—St. Mary's Hospital: Mr. F. A. Juler (ophthalmology), Mr. C. A. Pannett (surgery).

Dental Schools.—It was resolved that the Royal Dental Hospital and London School of Dental Surgery, and the National Dental Hospital and College forming part of University College Hospital Medical School, be continued as schools of the University in the Faculty of Medicine (in dentistry only).

Withdrawal of Scholarships.—It was decided to reduce the number of university scholarships to be awarded in the summer of 1916 from nineteen to twelve.

Staff Examiners for Medical Degrees.—The following were appointed staff examiners in the subjects of examinations for medical degrees:—*Anatomy*: Professor R. W. Reid; *Bacteriology*: Professor R. T. Hewlett; *Chemistry*: Dr. H. F. Morley; *Forensic Medicine and Hygiene*: Drs. E. P. Manby and F. J. Smith; *General Biology*: Mr. M. Davenport Hill; *Medicine*: Professors Norman Dalton and Arthur J. Hall; *Mental Diseases and Psychology*: Drs. R. H. Cole and W. H. B. Stoddart; *Obstetric Medicine*: Professor W. C. Swayne and Dr. G. F. Blacker; *Pathology*: Professors F. W. Andrewes and J. Martin Bantle; *Pharmacology*: Professor R. B. Wild; *Physics*: Dr. Sidney Russ; *Physiology*: Professor D. Noel Paton; *State Medicine*: Drs. T. M. Legge and R. K. Brown; *Surgery*: Professor W. P. Haslam and Mr. William Turner; *Tropical Medicine*: Professor F. M. Sandwith and Dr. C. W. Daniels.

Physiological Laboratory.—The annual report of the Physiological Laboratory Committee for 1915 stated that the normal work of the laboratory had been hampered by want of funds and absence of workers on military duty. The resources of the laboratory had again been held at the disposal of the War Office.

UNIVERSITY OF EDINBURGH.

OWING to the large reduction due to the war in the number of students attending, it has been resolved not to hold separate graduation ceremonies in arts and medicine, but a combined graduation ceremony for arts, science, medicine, and the other faculties, which will take place on July 11th. Sir James A. Ewing, K.C.B., the newly-elected Principal, is expected to take part.

At the last meeting of the University Court Dr. McKenzie Johnston was appointed a governor of the Fettes trust for the residue of the term of office for which the late Principal had been elected.

It was announced that Mr. Balfour had expressed the wish that the sketch portrait of himself by the late Sir George Reid, which Sir William Turner had bequeathed to him, should at once find a place in the University. The Court accepted the bequest, and thanked the Chancellor for his considerate regard for the University.

The Combe trustees have agreed that Dr. W. G. Smith shall be reappointed to the lectureship in psychology for a further period of five years from September 30th next.

UNIVERSITY OF ST. ANDREWS.

THE Senate has resolved to confer the honorary degree of LL.D. upon Dr. James Musgrove, Bute Professor of Anatomy in the University 1901-14, and now Emeritus Professor. Professor Musgrove graduated M.D. Edin. in 1888.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Election of President and Officers.—The annual election of officers took place on June 6th as follows:—*President*: William Taylor; *Vice-President*: John B. Story; *Secretary of the College*: Sir Charles A. Cameron; *Council*: William Stoker, Sir Charles A. Cameron, Sir Lambert H. Ormsby, Richard D. Purefoy, Henry Gregg Sherlock, Sir Thomas Myles, D. Edgar Fliun, Sir Arthur Chance, Shepherd McC. Boyd, Sir Robert H. Woods, R. Bolton McCausland, Thomas E. Gordon, Edward H. Taylor, F. Conway Dwyer, Alexander J. M.A. Blayney, R. Charles B. Maunsell, Trevor N. Smith, William Ireland Wheeler, Sir C. Arthur Ball. Mr. William Taylor, the new president, has a long association with the Royal College of Surgeons, in the schools of which he studied; he became Licentiate in 1893, and a Fellow in 1898, and in 1902 graduated in arts and medicine in the University of Dublin. Mr. Taylor is surgeon to the Meath Hospital and County Dublin Infirmary, and visiting surgeon to the Cork Street Fever Hospital. For the past two years he has been Vice-President of the College.

Lord Kitchener.—The College has adopted a resolution expressing its profound regret at the great loss the empire has sustained by the death of Lord Kitchener.

Obituary.

DR. ALFRED FREER, J.P., born at Stourbridge, Worcestershire, on March 15th, 1829, died at his residence in that town on June 10th, aged 87. His family had held leading positions in Stourbridge since 1547, and he himself was one of the fourth generation of doctors who lived at Green Close, Stourbridge. His great-grandfather, John Freer, was one of the first four surgeons appointed to the General Hospital, Birmingham, in 1779. Dr. Alfred Freer entered King Edward's School, Stourbridge (where Dr. Samuel Johnson had been an usher) in 1836. He began life as apprentice to a doctor at Birmingham, studying at the same time at Queen's College, and serving as a dresser at the General Hospital. In 1850 he took the diploma of M.R.C.S. and went, in order to study midwifery, to Dublin, where he became L.M. in 1851. At the end of that year he was working in the Paris hospitals, and witnessed Louis Napoleon's *coup d'état*. In 1852, after taking the L.S.A., he entered into partnership with his father and brother, and remained in practice for sixty-four years, for he was working only a few months ago at the Stourbridge dispensary during the temporary incapacity through accident of the resident surgeon, Dr. Lloyd Francis. Dr. Alfred Freer was a very active member of the British Medical Association. He was president of the Birmingham Branch in 1890, and became chairman of the Dudley Division, and representative for the combined Bromsgrove and Dudley Divisions. Until recently he was a very regular attendant both at the Branch and the Division meetings. Dr. Freer was the first president of the Stourbridge District Medical Society, Birmingham. Thirty-four years ago he was appointed a county magistrate. He took a great interest in church questions, Conservative and Unionist politics, and, latterly, in matters concerning the war. Dr. Freer was likewise known as a geologist, archaeologist, and chess player. He was held in universal esteem in the neighbourhood, where he laboured and was so long known and beloved that representatives of all phases of life attended in great numbers at his funeral on June 15th.

DR. FREDERICK JOHN WADD died at his residence at Richmond, Surrey, on June 12th, aged 71. He studied medicine at St. Thomas's Hospital and the University of Aberdeen, where he graduated M.B., C.M. in 1866; he also took the diplomas of M.R.C.S. and L.S.A. in the same year. Dr. Wadd was for many years the family physician to the Duke and Duchess of Teck at White Lodge, Richmond Park, and attended Queen Mary at the birth of the Prince of Wales; his grandfather was surgeon-extraordinary to George IV. He was for twenty-two years a member of the Richmond Town Council, and held the position of Chairman of its Health Committee for seventeen years; he was also one of the oldest supporters of the Royal Horse Show. A service was held on June 15th at St. Mathias's Church, Richmond, where the Queen was represented by the Hon. Alexander Nelson Hood, and the burial took place at Richmond Cemetery.

DEPUTY SURGEON-GENERAL EDWARD MALCOLM SINCLAIR, A.M.S.(ret.), died at his residence in South Kensington on June 14th, aged 84. He was born in 1832, the son of Dr. Malcolm Sinclair, and took the diploma of M.R.C.S. and the degree of M.D.St. Andrews in 1853. Entering the army as assistant surgeon on March 28th, 1854, he became surgeon in 1866 and surgeon-major in 1873, retiring as deputy surgeon-general on December 19th, 1888. He served in the Crimea in 1854-56, and was present at the siege and capture of Sebastopol, receiving the medal with a clasp and the Turkish medal. He served also in the Indian Mutiny from 1857 to 1859, when he took part in the operations in Oudh and in Bandakhand, including the actions of Chanda, Umirpur, and Sultaupur, and the capture of Lucknow, and received the Mutiny medal and Lucknow clasp. He was principal medical officer of the lines of communication and base in the Transvaal war of 1881, and was mentioned in dispatches.

Medical News.

THE annual general meeting of the Poor Law Medical Officers' Association of England and Wales will take place at its offices, 9, Copthall Avenue, London, E.C., on Friday, July 7th, at 4 p.m.

DR. A. E. LARKING, honorary secretary of the Buckinghamshire Division of the British Medical Association and of the Buckinghamshire Panel Committee, has been appointed a magistrate for the Borough of Buckingham.

THE Duchess of Marlborough will give the Lady Priestley memorial lecture of the National Health Society, on Thursday next at 5 p.m., at the Royal Society of Medicine, 1, Wimpole Street, W. The subject of the lecture is "Saving the Children." The chair will be taken by Sir James Crichton-Browne.

THE King has granted Dr. James Russell Watson of the English Baptist Mission Hospital, Tsing-chow-fu, China, licence and authority to wear the order of the sixth class of the Excellent Crop conferred upon him by the President of the Republic of China, in recognition of valuable services rendered.

THE annual meeting of the National Training School for District Midwives will be held, under the presidency of the Lord Mayor of London, at the Mansion House, on June 27th, at 5.30 p.m. The meeting will be addressed by Lord Balfour of Burleigh, Sir Dyce Duckworth, M.D., Lady Betty Balfour, and Dr. Barbara Tchaykovsky, and a statement will be made by the honorary secretary, Miss Alice Gregory, from whom, at the British Hospital for Mothers and Babies, Woolwich, tickets of admission can be obtained on application.

AT no period of its history has Great and Greater Britain stood in greater need for the preservation of child life than at the present time, and a great responsibility now rests upon those who have the care of the children of to-day. The formation of associations under whose auspices a number of centres have already been established to spread information as to the best means of preventing infant mortality has done much within recent years to reach the wives and mothers of the poor. The National League for Physical Education and Improvement (4, Tavistock Square) has recently published a small book, price 3d., entitled *To Wives and Mothers*, compiled for the most part from leaflets carefully drawn up by expert workers among the poor, in which a vast amount of sound advice is contained as to the preparations and precautions that the expectant mother must observe, and as to the proper management of the infant during the first weeks or months of life. The vital and far-reaching importance of skilful upbringing during the first five years of life, whether it be regarded from the physical or the mental standpoints, can hardly be exaggerated, but it is not by any means as fully recognized as it should be. A short section on character training inculcates some points which deserve the respectful consideration of mothers in all ranks of society, to whom we can cordially commend the pamphlet.

AT the monthly meeting of the Central Midwives Board on June 15th, when Sir Francis Champneys presided, a letter was read from the M.O.H. Chatham forwarding a circular letter addressed to all midwives in that district inquiring whether they would be willing to supply the names and addresses of expectant mothers with a view to facilitating antenatal visiting in connexion with infant welfare work, and asking whether the Board was taking any action. The Board replied to the effect that no midwife had any right to give any information concerning her patients to any one except with the consent of the patient, which, if possible, should be expressed in writing. The Board agreed to co-operate with the Board of Education in approaching the Treasury with a view to the provision of grants in aid of the training of midwives. The Board accepted with regret the resignation of Dr. W. Crump Beatey, one of the examiners of the Newcastle centre, and appointed in his place Dr. W. L. Ruxton. University College Hospital, London, was granted recognition as a training school. At special meetings of the Board on June 14th, 15th, and 16th, fifteen fresh penal cases were heard, and in six the midwives were struck off the roll. In three cases the Board decided to take no action. Apart from the usual charges of dirt, ignorance of the pulse and temperature, etc., there were several of neglect in cases of serious rupture of the perineum, puerperal fever, and ophthalmia. Reports on four adjourned cases were heard; they were all satisfactory. The names of two women were removed from the roll on their own application.

Letters, Notes, and Answers.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2530, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2534, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

H. D. asks whether at temperance hospitals where no brandy, etc., is given as a stimulant, absolute alcohol or any other substitute is prescribed, and if so in what doses.

M.D. writes: I want to find a place for two months or so for a strong healthy young woman who expects her accouchement in the early autumn. She will, I understand, be received into Queen Charlotte's Hospital, but not until shortly before the expected birth of the infant. In the meantime she is unable to remain in her present situation or to go home. Any suggestions for assistance will be gratefully received.

HARVEST BUGS.

M.D. asks whether there is any reliable prophylactic, or failing that remedy for the bites of harvest bugs.

The harvest bug, *Leptus autumnalis*, is the larva of a species of trombidium, usually *Trombidium holosericeum*, and was described by Dr. Shipley in one of his articles on insects and war (BRITISH MEDICAL JOURNAL, October 31st, 1914, p. 750). The article was republished in *The Minor Horrors of War*, p. 87 (Smith, Elder, and Co. Price 1s. 6d. net.). The irritation is caused by the mite implanting its mouth parts in the skin, preferably in the hair follicles or sweat glands. Dr. Shipley says that they may be "dislodged by the application of petrol or benzine, both very inflammable, and the itching they cause allayed by the application of acid or alcoholic lotions." In the late Dr. Radcliffe Crocker's *Diseases of the Skin*, we read, "The treatment is by mild parasitocides, such as are used in scabies, naphthol or weak sulphur, or white precipitate ointment. The soaking and scrubbing necessary for scabies are superfluous here."

ANSWERS.

ACNE ROSACEA.

D. writes: If "S," who asks as to the treatment of acne rosacea, will use this ointment and push the application almost to blistering, he will cure his patient. R. Hyd. iod. rub. gr. iv; att. rosae m ij; vaselin. $\frac{1}{2}$ oz. Apply with a brush once a day in the early morning, so that the severe smarting will have passed off before bedtime. He must return to the attack when and as often as may be necessary.

LETTERS, NOTES, ETC.

WILLIAM LAWRENCE'S "TREATISE ON HERNIA."

MR. J. Y. W. MACALISTER (Secretary, Royal Society of Medicine, 1, Wimpole Street, W.) writes: In my note which you kindly inserted, asking for the help of your readers to find a book entitled *Treatise on Hernia*, the name of the author was given as "Henry Lawrence" instead of, as of course it should be, "William Lawrence."

THE FRESH AIR CRAZE.

DR. D. W. SAMWAYS (Exeter) writes: Is it not time more discrimination were shown by the medical and nursing professions in the advocacy and employment of fresh air? When healthy people or invalids sit out of doors they choose a sheltered place, as free as possible from draughts, but in our wards it is the habit to open windows on all sides as generously as possible, without any consideration of the consequent draughts. Some friends of mine were lately present at a concert given to the patients at the Brompton Hospital. So great was the draught that music put down on the piano was actually blown off, while two assistants were required to hold in place any piece of music which was being played.

If debilitated consumptives profit by the fashion for draughts, which I doubt, why treat all patients as consumptives? Is the whole body a respiratory orifice? I find it almost impossible to prevail upon sisters to close the windows on the weather side of a ward when a cold wind is blowing, and open those on the lee side. They have always been taught that there cannot be too much fresh air.

Who of us suffering from colds, laryngitis, bronchitis, rheumatism, neuralgia, or insomnia would sit or sleep in a draught? Yet our patients have to suffer these things because of this fresh air fetish.

It has been established that pure air is eminently desirable for all. Fresh air, which is now almost synonymous with cold, draughty air, seems to me responsible for more ailments than it averts.

In the high Swiss health resorts the consumptive is supplied at night with still air by the protection of heavy curtains, and with warm air by hot pipes, the aim being to provide pure air, not cold draughts.

I maintain that the medical profession should cease the advocacy of fresh air. It is as risky to advocate fresh air as fresh water, both of which have killed or disabled numberless unwary people. It is pure air and pure water which alone are desirable, the pure air being reasonably warm and free from draughts. Till sisters and nurses are taught this, railway station ventilation will probably continue to be their ideal.

VALUE OF TUBERCULIN TREATMENT.

DR. JOHN MACKEITH (London, W.) writes: Although "Medicus" (JOURNAL, June 10th, p. 840) states that his "present opinion is that if I had continued tuberculin I would not now be penning these lines," yet I consider his present very satisfactory state is much more to be attributed to the immunizing effect of the tuberculin he had than to "silence treatment aided by the climate of Madeira," although these doubtless acted beneficially on his condition. One of the effects of tuberculin is to produce an active hyperaemia at the focus of disease, resulting in the formation of antibodies. This hyperaemia may sometimes, in cases of laryngeal tuberculosis, be attended by temporary aggravation of the symptoms, with an apparent exacerbation of the disease, as is observed on laryngeal examination. This action, if not excessive, leads to healing and cicatrization. Late and large doses of tuberculin, given in the course of treatment, do not produce hyperaemia, and yet result in the formation of antibodies. In my experience there is no method of treating laryngeal tuberculosis that can in any way compare with the favourable results obtained, in any series of cases, by tuberculin treatment. I have before me the notes and charts of three cases of pulmonary tuberculosis (tubercle bacilli present), with extensive laryngeal affection, all treated with tuberculin alone, and without rigid "silence treatment" or any climatic effect, other than that to be obtained in the neighbourhood of London, with perfectly satisfactory results to the patients. The result of treatment may not always be evident at once, because in cases of ulceration there is a mixed infection, and though tuberculin may have done its work well, time is often necessary for the slow recovery from the other infections. As one who has used tuberculin in large doses, both at the tuberculin dispensary and at the Central London Throat, Nose, and Ear Hospital, I can testify to the absence of any real danger in the use of tuberculin in the hands of an expert.

A CASE OF ABNORMALLY LARGE PLACENTA.

DR. H. WESSEN HUSBANDS (Taunton) writes that in a case of ante-partum haemorrhage, to which he was called by a midwife, he found the vertex distending the vulvar outlet, and the child was even born. Owing to the continuance of haemorrhage the placenta was delivered quickly, when the bleeding was controlled and the uterus became hard and firm and remained so. It was the ninth pregnancy, the labour being premature and the child stillborn. The weight of the fetus was 6 lb. 11 oz. The weight of the placenta was 6 lb. 14 oz. The patient had a normal recovery.

VALLAURI PRIZE.

THE Royal Academy of Sciences of Turin offers the prize founded by Ernesto Vallauri to the scientific investigator who in the four years from January 1st, 1915, to December 31st, 1918, shall have published the best work on any of the physical sciences, that expression being interpreted in the largest sense. Works offered in competition must be printed. The prize, which is of the value of £104, is open to foreigners.

A CORRECTION.

MAJOR RUSSELL COOMBE, R.A.M.C.(T.F.) (Exeter), writes: Will you kindly allow me to use your columns to correct an error in the Director-General's recent circular? I am not, as there described, consulting surgeon to the Devon and Exeter Hospital.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postae restante* letters addressed either in initials or numbers.

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1916.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

INDEX TO THE EPITOME FOR VOLUME I, 1916.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

ABADIE, J.: Extension apparatus for fracture of humerus, 40
Abdomen, gunshot wounds of (Kraske), 52
Abdomen, wounds of (Marquis), 41
ALESSANDRI, R.: Acute Raynaud's disease with paralysis, 18
AMEVILLE, F.: Nephritis in soldiers in the field, 32
Anaesthesia by the rectum in thyroidectomy (Lathrop), 12
Anaesthetic in war surgery, ethyl chloride as (Jacques Carles and A. Charrier), 55
ANDERSON, E. A.: Mercury salicylate in syphilis, 11
Antiseptic, magnesium hypochlorite as an (Charles Mayer), 57
Atrophy, sling (Rochard and Stern), 84

B.

BARRINGER: Cardiac insufficiency, 17
BEAUSSENAT, A.: Extraction of projectile from the heart, 71
BELIN: Powdered potassium permanganate in wounds, 9
BERGONIÉ: Pulsatory pneumatic massage, 7
BERTARELLI, A.: Treatment of septic wounds, 33
Blindness, night, in soldiers (Wecker), 81
BLUM, Edgard: Simulated disease in soldiers, 75
BOIDIN: Typhoid and paratyphoid mortality, 48
Bone atrophy, non-infectious (Grey and Carr), 15
Bordet-Gengou test in echinococcal infections (L. C. Zappelloni), 29
Brachial plexus, traumatic paralysis of, without fracture or dislocation (Levison), 20
BRANDT: Fatal septicaemia due to intra-uterine pessar, 24
BROUQ: Influence of war on skin affections, 59
Bullet in heart, shrapnel (Richard Freund and Carl Caspersohn), 64

C.

CANE, Captain L. B.: Gas gangrene, 72
Cardiac insufficiency (Barringer and Teschner), 17
CARLES, Jacques: Ethyl chloride as an anaesthetic in war surgery, 55
CARR: Non-infectious bone atrophy, 15
Cartilage transplantation in plastic surgery (Morestin), 62
CASPERSOHN, Carl: Shrapnel bullet in heart, 64
CASTEX, Andre: War deafness, 54
Cerebro-spinal fever. *See* Fever
CHAMBA, Gustave: Scarlet fever in the French army, 30
CHARRIER, A.: Ethyl chloride as an anaesthetic in war surgery, 55
CHAVANNE: War deafness, 43
CHAVIGNY: Treatment of nervous disorder in soldiers, 66—War psychiatry, 74
Conception and menstruation, relation of (P. W. Siegel), 23
COTTON: Limitations of the x ray, 21
ORILE: Experiences of American military surgery, 2

D.

Deafness, war (Marcel Lermoyers), 6—(Lannois and Chavanne), 43—(Marage), 43—(Andre Castex), 54
DIMER, Gaston: Simulated disease in soldiers, 75
DÖHNER, B.: X-ray picture of gas phlegmons, 65
Dressings, gaseous bags as (Morisot), 37
Dysentery, prophylactic inoculation against (G. S. Sieffert and O. Niedieck), 85
Dysentery, treatment of (P. Emile Weil), 46—(Milian), 46

E.

Echinococcal infections, Bordet-Gengou test in (L. C. Zappelloni), 29
Electro-vibration in localization of foreign bodies (Phocas), 45
ELOSSE, L.: Experiences of German military surgery, 2
Enteric fever. *See* Fever
Erysipelas, facial, painting with methylene blue solution in (Nobécourt), 10
Ethyl chloride as an anaesthetic in war surgery (Jacques Carles and A. Charrier), 55
Extension apparatus for fracture of humerus (J. Abadie), 40
Extrasystoles after injury by shrapnel (O. Josué and Jean Heitz), 68

F.

FAUNTLEROY: Gas bacillus infection, 73
FERRERO, Gherardo: Lesions of the larynx and trachea in war, 60
Fever, cerebro-spinal (Jean Pignot), 47
Fever, enteric, mortality (Boidin), 48
Fever, scarlet, in the French army (Félix Ramond and Gustave Chambas), 30
Fever, scarlet, the pulse in (Nobécourt), 31
Fibrolysin in recent cutaneous scars (Henri Toussaint), 86
FORD: Hydatidiform mole: chorion-epithelioma: bilateral corpus lutein cyst, 25
Foreign bodies localized by electro-vibration (Phocas), 45
FORGUES: Simulated disease in soldiers, 75
Fracture of humerus, extension apparatus for (J. Abadie), 40
Fractures of the patella in war, 63
FREUND, Richard: Shrapnel bullet in heart, 64

G.

Gas bacillus infection (Fauntleroy), 73
Gas gangrene (V. Marconi), 72—(Giovanni Tiengo), 72—(N. Leotta), 72—(Captain L. B. Cane), 72
Gas phlegmons, x-ray picture of (B. Döhner), 65
Gas in the tissues (Woodburn Morison), 38
Gaseous bags as dressings (Morisot), 37
Gastric crises in tabes, surgical treatment of (Georges Patry), 19
GAUCHER: War and skin disease, 77—Syphilis in war time, 78
GAUD, M.: Acute nephritis in soldiers on active service, 67

GERVER, A. B.: War psychoses, 50
GIBON: X-ray images in stereoscopic relief on the screen, 39
Gonorrhoea treated with optoquin (Levy), 27
GOURBEAU: Treatment of syphilis in war, 56
GREY: Non-infectious bone atrophy, 15
GUISEZ: Direct laryngoscopy in war wounds, 61
Gunshot wounds of abdomen (Kraske), 52
Gunshot wounds of skull, radiography in (Vilvandré), 80

H.

Haemophilia calcipriva (Hess), 16
HALSEY, W. H.: Submarine casualties, 49
HAMILTON: Typhoid vaccination, 26
Hand, chronic traumatic oedema of the back of (L. Levy), 44
HANSEN: Treatment of laryngeal tuberculosis, 13
Heart, extraction of projectile from (A. Beaussehat), 71
Heart, shrapnel bullet in (Richard Freund and Carl Caspersohn), 64
HEITZ, Jean: Extrasystoles after injury by shrapnel, 68
HESS: Haemophilia calcipriva, 16
HIRSCH, C.: Isolated vestibular neuritis following typhoid inoculation, 1
Humerus, extension apparatus for fracture of (J. Abadie), 40
Hydatidiform mole: chorion-epithelioma: bilateral corpus lutein cyst (Ford), 25
Hyperaemia in treatment of wounds (E. Sebrt), 83—(Linberger), 83

I.

Inoculation, antityphoid (Hamilton), 26. *See also* Typhoid
Intracranial projectiles, extraction of under fluorescent screen (Rouvillois), 82

J.

JOSUÉ, O.: Extrasystoles after injury by shrapnel, 68

K.

KLEIN, Mdlla. Renee: War and skin disease, 77
KRASKE: Gunshot wounds of abdomen, 52
KREFFING, E.: Treatment of syphilis with salvarsan only, 28
KÜSTER, H.: Disinfection of the meningococcal carrier, 58

L.

Labour, management of placental stage of (Polak), 22
LANNOIS: War deafness, 43
Laryngoscopy, direct, in war wounds (Guisez), 61
LARYNX and trachea, lesions of, in war (Gherardo Ferreri), 60
LATHROP: Anaesthesia by the rectum in thyroidectomy, 12

LE FORT, René: Fractures of the patella in war, 63
LEOTTA, N.: Gas gangrene, 72
LERMOYER, Marcel: War deafness, 6
LEVISON: Traumatic paralysis of brachial plexus without fracture or dislocation, 20
LEVY: Treatment of gonorrhoea with optoquin, 27
LEVY, L.: Chronic traumatic oedema of the back of the hand, 44
LINBERGER: Treatment of wounds by hyperaemia, 83
LONGIN, A.: Trench foot, 3
Lung, extract of fragments of projectile from (Mauclaire), 35—(G. Marion), 70—(Petit de la Villéon), 70
Lupus in the Austrian army (Ludwig Spitzer), 53

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. Isolated Vestibular Neuritis following Typhoid Inoculation.

C. HIRSCH (*Deut. med. Woch.*, August 19th, 1915) records the case of an army surgeon, who had previously been well. The first inoculation was well tolerated, but twenty-six hours after the second inoculation the patient became exceedingly giddy and developed severe vomiting, which was renewed on the slightest movement of the head. During the following night the pulse and respiration were abnormally slow, there were spasmodic contraction of the muscles of the jaw, and a cold sweat and numbness of the fingers were accompanied by tinnitus. The patient diagnosed embolism, thrombosis or abscess of the cerebellum on the left side, and asked for an operation. A more detailed examination showed that the right tympanum was reddened, and that the patient tended to fall over to the right on walking. An ophthalmologist could find nothing amiss with the eyes, and diagnosed haemorrhage into the left labyrinth. Four weeks after the development of the first symptoms the patient still felt giddy on turning his head or eyes, especially on rotation to the left. There was marked ataxia on rapid movement, the patient was incapable of much exertion, and was easily excited by small doses of alcohol or coffee. The nose and ears seemed perfectly healthy, Romberg's sign was negative, and there was no spontaneous nystagmus nor deafness. Wassermann's reaction was negative. The author came to the conclusion that the inoculation had caused neuritis of the vestibular branches of both auditory nerves, the nerve on the right side being most affected. On May 3rd—that is, three months after the onset of the symptoms—the patient could resume his surgical work at home. Only when he moved his head quickly did he still experience slight giddiness.

SURGERY.

2. Military Surgery.
American.

CRILE (*Annals of Surgery*, July, 1915) narrates the history, equipment, and experiences gained at the Lakeside Unit of the American Hospital for wounded situated in Neuilly, a suburb of Paris, comprising a service of 150 beds, with an average performance of from five to ten operations per day. Compared with civil practice, these operations were simpler in technique, but offered more difficult problems as to the proper procedure in the more severe injections. Nitrous oxide-oxygen was the ideal anaesthetic, as many of the operations were relatively short and performed upon exhausted, exsanguinated, and extremely septic patients, and the advantages of this anaesthetic became so obvious that the anaesthetists and gas were utilized by other services in critical cases. While the stage of induction was found to be longer and more difficult in the French soldier than in the average American civilian, a relatively smaller amount of the anaesthetic was required after induction was completed, and a smooth and even anaesthesia was more easily maintained. Almost every wound was infected, a sepsis and antiseptics having failed in military surgery, the type of infection depending in a measure on the type of injury, the state of the soldier, and the interval elapsing before the wound could be adequately treated. Shell and shrapnel wounds produce a larger zone of contused and devitalized tissue having a low resistance to infection than do rifle wounds, and as most cases of gas gangrene follow shrapnel and shell wounds, these are promptly treated by clearing out foreign bodies, excising the devitalizing tissue, and providing good drainage. Many observers advise warm moist dressings, immersion in hypertonic solutions of potassium citrate and sodium chloride, and in severe knee and thigh injuries immersion of the patient in a bath, while apparently better results followed open-air treatment after a certain stage was reached, and exposure to electric light has been advocated. The best treatment up to date appears to consist in hot packs, immersions in hot water, free incisions, good drainage, and physiologic rest. Death from gas gangrene is caused by structural injury of the brain, adrenals, and liver, and the best hope for

recovery apparently rests with prompt amputation, leaving the stump wide open, and applying hydrogen peroxide. Next to infection, shock and exhaustion with emotional strain were probably most fatal, and in many cases very slight injuries caused great shock and even death. The best treatment for shock under the difficulties encountered in engagements is to give morphine. For compound fractures Blake's splint and the Balkan splint are among the most efficient. Stress is laid upon the urgent need for research into the control of infections, and in organization it would appear that the best results will be achieved by placing the Army Medical Service in charge of the field service, since these surgeons, whilst relatively untrained in surgical practice, are highly trained in organization, transportation, etc., and placing the heavy surgical work in charge of civilian units composed of surgeons untrained in military organization, etc., but highly trained in the actual care of the patient, and by having attached to each base hospital a board of consultants, composed of the most expert surgeons, responsible for the practical work and the formulation of general principles.

German.

L. ELOESSER, of San Francisco (*Journ. Amer. Med. Assoc.*, December 4th, 1915) gives his impressions of German military surgery as observed in the army reserve hospital at Ettlingen, Baden. Nearly all the wounded treated there came from the west front, where, owing to the nature of the fighting, most were shell and shrapnel wounds. Infantry and artillery fire cause different kinds of injuries. A man hit by an infantry bullet is either out of danger quickly or dies quickly, according to the part involved. If struck by a piece of shell, unless the wound is altogether superficial, he is an object of anxiety for weeks or months. There are exceptions, of course, to this general rule. The modern small calibre bullet by no means always makes a small smooth wound. The nature of its path is determined partly by the character of the bullet and partly by the part struck. Whether the bullets are pointed, like the English, French, and German bullet, or more snubbed, like the Russian missiles, does not seem to make much difference. The real difference is due to whether the points are smooth or have been notched or dented or otherwise deformed, either by the soldiers themselves or by more concerted arrangements, for Eloesser claims that there have been instances of manufactured dum-dum bullets, made in factories, taken from captured soldiers. A bullet with a nicked or hollow point no longer merely pierces. Evidence of a dum-dum bullet can only be got from an unspent bullet itself. The shape of the bullet is also of importance and the position of its centre of gravity. If the latter is near the rear it causes the bullet to turn in its course, when the point meets resistance, and make a more destructive track. Eloesser credits the French copper encased bullet with being most humane and the English bullet perhaps the worst, with its anterior core of aluminium and centre of gravity far back. If a bone is shattered each splinter acts as an additional projectile. Injuries to the skull are of three kinds—tangential, penetrating, and perforating. Most injuries seen at the base hospital are of the first kind; the other patients usually die before they get there. Although the wounds usually heal kindly, the patients are often permanently incapacitated from organic or functional brain disturbances. In case of a patient surviving a penetrating wound, a roentgenogram is advisable, as bullets or deep indentations and splinters are often found. Late abscesses often develop, and may be difficult to diagnose. The osteoplastic closure of Garré, with a flap of bone shavings from the outer lamina and periosteum, is sufficient for defects on the vault of the skull. When there is a deep defect in the forehead, a free transplant of bone may be used. Chest wounds do not give as little trouble as is generally supposed. Gunshot wounds of the extremities have increased in gravity with the increased power of the modern small arm; nerves and vessels cannot evade the modern bullet. The nerves are liable to be involved in scars, affecting their functions, and operation may be desirable. Fractures from the small calibre bullet, even with wide shattering of the bone, usually heal promptly. The question how to transport fracture patients is still unsettled; there is no time for applying plaster splints on the battle field. It is the wounds from shells and artillery projectiles which make one realize what war is.

Shells used in the beginning of the war broke up into large pieces or lumps. Another kind, which Eloesser says are of American manufacture, burst into jagged slivers with saw edges. Shell wounds are always infected; it may not be severely but generally is and seems to be getting worse as the war goes on, as Eloesser supposes, from the dirtier uniforms and the more infected soil. Tetanus has largely disappeared with the use of prophylactic injections. The dictum of "hands off" is not valid for shell wounds, as is being realized more recently. Gas phlegmons are of several types and should be laid wide open. The pus appears too quickly to be followed up, and in order to prevent its travelling upward it is well to cut the main subcutaneous veins across some distance above the wound. The after-care is one of the most difficult things in the surgery of these cases. On September 5th the Ettlingen Hospital was made a purely orthopaedic institution and run in connexion with the school for the one-armed and an institution for the care and training of cripples, and wound cases were not received. Every conceivable method is used to train the disabled for some future useful occupation, but Eloesser seems to think there will be many shirkers and pension grabbers after the war, and that it is quite likely that some law to keep cripples from idleness will be required.

3.

Trench Foot.

A. LONGIN (*Ann. de derm. et syph.*, Tome v, No. 11, October, 1915) classifies "trench foot" in three degrees: (1) A primary stage of oedema, to which the term "succulent" has been applied by neurologists. The colour of the part is white, sometimes cyanotic, and, if lymphangitis is superimposed, of a roseate hue. The oedema, though apparently superficial, involves all the structures of the part affected, so that the joints tend to become distended, and the patient may afterwards be severely handicapped by the laxity of his ligaments when the fluid is absorbed. (2) In the second stage the epidermis is distended by the presence of bullae, containing a serous or blood-stained fluid. These vary in size from that of a pea to a nut, and the more blood-stained the fluid the more should one suspect a deep-seated origin, and the more likely the possibility of gangrene supervening. (3) The third stage is that of gangrene, which may be either insular and superficial, or deep and usually leading to the loss of one or more toes, most often the little and big toes, and not infrequently stopping short at the proximal phalanges. The lateral aspects of the feet are more prone to gangrene than the central, and the line of demarcation may quite frequently therefore be V-shaped. Almost invariably the sole suffers more than the dorsum. The quantity of oedema present in these cases would appear to determine whether the supervening gangrene shall be of the dry or moist variety, and, according to Longin, the latter and far more serious complication may sometimes be avoided by incising and dehydrating the tissues with currents of hot air. The etiology is almost invariably the same. The men have been standing for hours at a time in water or mud, and in practically every case of a temperature considerably above the freezing point, and to these factors the tight application of puttees is doubtless contributory. The resulting vascular spasm and paralysis are the immediate causes of the affection, which has pathological resemblances to Raynaud's syndrome. The symptoms are commonly a feeling of distension at first, and the patient may not even be incapacitated from marching for a time. Presently, however, shooting pains and sensations of heat develop in the feet, and become more acute from day to day, so that the patient is forced to report sick. In the stage of gangrene the affected parts are, of course, completely insensitive to every form of stimulus, and there is usually acute pain at the line of subsequent demarcation of dead from living tissue. The treatment of this very disabling condition is of great importance. Asepsis should be undertaken systematically in every case, especially when the oedema is marked. Footbaths in warm water, followed by gentle friction with alcohol or ether and compresses with Hoffmann's anodyne (spt. etheris nit.), are very useful in the early stages. The hot air douche followed by these compresses has been of the greatest benefit in the author's cases. The temperature should be only a little above that of the blood. In a few cases in which the burning sensations were paramount, cooling lotions had to be exhibited for a time. In cases of moist gangrene the air douche finds its most potent application, and it was most useful in stimulating ulcers left after separation of sloughs, and in causing them to heal. The surgical removal of dead tissue must be entirely governed by a due consideration of each individual case. A minimum of loss should always be aimed at, and it is emphasized that the

length of treatment should be a purely secondary consideration. Longin's method of amputation has been largely by means of carbonization with air at a temperature of 700° to 750° C. and not with the knife, which, in his opinion, tends to open up fresh channels of infection, and the possibility of further gangrene and danger to life. Finally, the prophylactic administration of tetanus antitoxin is recommended in all cases of moist gangrene, as the bacillus finds an acceptable nidus in the devitalized tissues, and several cases of the disease have already been reported.

4. Magnesium Sulphate Solution for Septic Wounds.

MORISON and TULLOCH (*British Journal of Surgery*, October, 1915) from experience in the Northumberland War Hospital, where wounds are often seriously infected before the patients are admitted, and where neither asepsis is possible nor antiseptics of any service, report favourably on magnesium sulphate, which by virtue of its being absorbed with difficulty has certain advantages over other salts used for cleansing wounds by osmosis. It also appears to have the desirable property of interfering with the digestive activities of pus, and inhibits to some extent the growth of certain bacteria commonly found infecting wounds. The authors employ a saturated solution of the salt. Forty ounces of magnesium sulphate are dissolved in ten ounces of glycerine and thirty ounces of water, and sterilized in an autoclave. In recent injuries the wound is freely opened up, the foreign body removed, and the whole wounded surface swabbed with pure carbolic acid. The ends of fractured bones are treated in the same way, and loose but attached fragments are not removed. The wound is gently packed for twenty-four hours with gauze wrung out of carbolic lotion (1 in 20) and antiseptic wool applied as an outer dressing. At the end of this time the wound is dressed; the gauze plug removed, the wound is syringed out with magnesium sulphate solution, and loosely packed with sterile gauze wrung not too hard out of the same solution, and the whole area of the wound is then covered with a double layer of gauze or lint saturated with solution over which a piece of jaconet, and then cotton-wool, is placed, the whole being fixed loosely by a bandage. In the case of wounds of later date, where sepsis and suppuration are fully established, no carbolic acid is applied, but the magnesium sulphate treatment is commenced at once. Even in the worst cases, the dressings are only changed every twelve hours. Within two or three days the pus has almost disappeared, the sloughs begin to separate and the surface of the wound presents a bright red colour. The granulations never become flabby or oedematous, and the epithelium grows freely from the edges of the wound. The treatment may be continued with advantage until the entire wound is healed.

5. Paralysis of Tongue from Traumatic Division of Hypoglossal Nerves.

MORESTIN (*Soc. de Chirurg. de Paris*, June 23rd, 1915) records the case of a soldier who eight months ago was wounded by a bullet which passed from one side to the other in the infrahyoid region. The tongue is completely paralysed, and no cicatrices are present; its surface and contour are normal. On palpation, no induration can be felt; indeed, the tongue is uniformly very supple and flaccid. Taste and tactile sensibility of the organ are perfect. In the act of swallowing solids the tongue appears to take no part; the patient has to throw his head back and push the bolus backwards with his finger; saliva is swallowed with great difficulty, and there is constant slobbering. The patient can speak slowly in a sticky voice, but he is quite easy to understand. No change has occurred during five months' observation; and prognosis is held to be very bad. The lesion is attributed to division of both hypoglossal nerves by the bullet.

6.

War Deafness.

MARCEL LERMOYEZ, in a paper on war deafness, an abstract of which appears in the *Progrès Médical* for December, 1915, says there are two kinds of traumatic deafness, direct and indirect. The true war deafness is the indirect. The hearing is destroyed by a sudden inrush of air into the auditory meatus which violently strikes the tympanum; it is not the noise that causes deafness, but the "wind of the bullet." The best chance the labyrinth has of escaping is when the chain of ossicles does not work well. The prognosis varies according to the resistance of the drumhead. If the labyrinthine disturbance is slight the patient will recover his hearing without local treatment, and will be fit for service in a month. If it is serious, the man will remain unfit for military duty. Strychnine may hasten the resolution of certain curable forms of

inflammation of the auditory nerve, provided it is given in sufficient doses. Two or three injections of 2 mg. may be given daily, but not for more than a fortnight at a time on account of the danger of cumulative action. Electricity is useless.

THERAPEUTICS.

7. Pulsatory Pneumatic Massage.

BERGONIÉ (*Arch. d'electr. méd.*, October, 1915) describes a new method of physiotherapy, which he calls "pulsatory pneumatic massage," for the treatment of the after-effects of wounds. He states that if an appliance, such as the pneumatic drum of Marey's chronograph—that is to say, a closed cavity with rigid walls, save for one only, which is supple and elastic—be placed on the dorsal surface of a stiff or ankylosed hand or on any cicatricial lesion in such a manner that the elastic portion covers the part, it is possible by rhythmic variations of pneumatic pressure transmitted to this appliance from an air pump to massage mechanically the cicatricial stasis which is sometimes the despair of surgeons and physiotherapeutists. The drums or receivers, which may be of various sizes and surfaces to suit different parts of the body, are mechanical excitators similar to the excitators used in electrotherapy, but act by alternations of pressure instead of by alternations of potential. Several of them may be served from the one source of pneumatic pressure by means of a series of branch pipes, and the volume of air passing into each may be regulated by the length and diameter of the pipes as well as by a system of faucets. The transmitting arrangement is an air pump, having a cylinder proportional to the number and capacity of the receivers. The pressure may be as great as 1 kilogram per square centimetre, or even more, or it may be so slight as scarcely to brush the skin. The frequency of alternation varies with the number of movements of the piston, but 120 a minute appears to be the best. This elastic and rhythmic pulsatory pressure acts on the vessels, on the circulation, and also on the cells, stimulating nutrition and tissue exchanges. It has been found specially useful in the impotences which follow splinter fractures of the hand, in stiffness of finger-joints, in oedemas and trophic troubles, in tendinous and muscular coalescences, etc.; in fact, in all the secondary lesions and sequelae of wounds in which massage ordinarily is efficacious. The author does not bring forward this method as a means of replacing manual massage performed by an instructed hand, but it has the advantage of being capable of application simultaneously to a number of cases.

8. Treatment of Mutism following Injuries of War.

MARAGE has studied more than a hundred cases of mutism following directly on injuries in warfare (*Compt. rend. de l'Acad. des Sciences*, No. 20, November 15th, 1915). As a sequel of a cerebral concussion, without apparent lesion, caused by the explosion of a large shell, the patient, after a loss of consciousness varying in duration from a few minutes to many days, fails to recover his speech. In 64 out of 100 cases this mutism disappeared spontaneously at the end of some weeks, but in the remainder all kinds of treatment completely failed. The mutism is often accompanied by vertigo and distressing tinnitus, and all the patients complained of very violent frontal headache. Insomnia is the rule, and often for two or three months there may be only an hour or two's sleep at night. There is more or less marked defect of memory; not only are all events following the battle forgotten, but the patients cannot write a letter, owing to their defect of memory. Auditory hyperaesthesia is so great that sounds which are barely perceptible to a normal ear are described as intolerably loud. During the last five months Marage has treated 5 cases of complete deaf-mutism. As he found that their respiration was very defective, he gave them respiratory exercises. At the end of fifteen days their expiration was of good amplitude, but they could not speak, however much they tried. In addition the larynx and sides of the neck were massaged by a mechanical or electrical vibro-massage instrument, both the intrinsic and the extrinsic laryngeal muscles being stimulated. After four days the patients began to whisper simple words—for example, "papa," "mamma," "good morning," etc. After eight days' treatment they could repeat phrases written down for them. After three weeks two patients spoke naturally. But a third had such an extremely defective memory that he could not repeat a word of three syllables, owing to the fact that after repeating two

syllables he had forgotten what the third was; however, he improved later on. Marage thinks that this simple mode of treatment is worthy of use in military hospitals.

9. Powdered Potassium Permanganate in Wounds.

BELIN has for more than ten months treated all cases of wound seen by him during the war by the application of potassium permanganate in the form of powder (*Soc. de Pathol. Comparée de Paris*, October 12th, 1915). Before the war he showed how surprisingly quickly wounds cicatrized under this treatment. In the very worst wounds of warfare this followed within fifteen days. He finds that the permanganate soon ceases to be a very powerful antiseptic, and becomes a cicatrizing agent. The powder gives up its oxygen unceasingly to the plasma of the wound and to its cells. The pain becomes quite bearable. This treatment has the virtues of being easy to apply; the powdered permanganate is non-toxic, antiseptic; its action is durable; it adheres to the wound, favours its cicatrization, destroys bacteria, and protects the patient from infection by anaerobic microbes, such as those of tetanus, gaseous gangrene, and haemorrhagic septicaemia.

10. Painting with Methylene Blue Solution in Facial Erysipelas.

NOBÉCOURT (*Bull. et mém. Soc. Méd. des Hôp. de Paris*, December 2nd, 1915) has treated a large number of soldiers affected by facial erysipelas by painting with a 5 per cent. aqueous solution of methylene blue. He finds it very efficacious and even better than ichthyol or tincture of iodine; several of his colleagues have testified to its value. The solution is painted over the erysipelatous area, and also over the neighbouring unaffected skin for a distance of 1 cm. every night and morning; no dressing is necessary. The effect is very marked on the pain; in half an hour to an hour the patients have a sense of well-being, and forthwith their pain ceases. Digital pressure gives no pain, or at most a disagreeable sensation when applied over the scalp. No hypnotic nor anodyne drugs are needed. The swelling and oedema subside rapidly, and even when the eyelids have been closed by the oedema, the latter passes away almost entirely within two or three hours. The course of the disease is cut short, so that in most cases it is arrested on the first or second day; only rarely is the treatment necessary for more than two or three days. The slight staining of the bed and body linen can be avoided by due precautions. After cessation of the treatment the blue colour of the painted skin persists for several days, up to a maximum of six or eight, and it disappears spontaneously or by washing.

11. Mercury Salicylate in Syphilis.

KENT NELSON AND E. A. ANDERSON (*Journ. Amer. Med. Assoc.*, November 27th, 1915) report their experience with mercury salicylate in the treatment of syphilis. The patients were prisoners in the military prison at Fort Leavenworth, Kansas, and the facilities for observation and care were excellent. Each patient had had at least two double plus serum reactions at different dates before the investigation, and none had had previous treatment of any character. Unfavourable influences that could affect the treatment were thoroughly excluded, and no other treatment was used. The dose in all cases was the same—1½ grains. At first it was repeated every seventh day, and after this was found to be too short an interval, every fourteenth day, and at times a longer interval was allowed between doses. None of the patients were salivated, though they were kept saturated with the drug, and all completed their daily quota of work. Sore buttocks were complained of sometimes from the injections, but inflammation was kept down, and no serious objections were made by the patients. Objective symptoms yielded to the treatment, but much less rapidly than to salvarsan, and the authors do not think that a combination of the two favourably affects the treatment. While they hesitate to say that the mercury salicylate treatment of syphilis is altogether valueless, they hold that it has little influence over the disease.

12. Anaesthesia by the Rectum in Thyroidectomy.

LATHROP (*New York Med. Journ.*, November 13th, 1915) claims favourable results by the practice of oil-ether colonic anaesthesia in thyroidectomy where freedom of movement is essential and where the ether cone is absent.

The anaesthetic can be applied in bed, and the unconscious patient removed to the operating table and the thyroid excised with little or no conception of what has taken place. The pulse and respiration remain, as a rule, normal. The rapid pulse of hyperthyroidism remains quick, but does not increase as when fear is added to the patient's troubles. The cases under Lathrop were thyroidectomies (excepting one ligation) for (1) hyperthyroidism, 15 cases; (2) parenchymatous thyroid tumours, 38 cases; and (3) colloid and cystic tumours, 58 cases. There was only one death, in a case of exophthalmic goitre, three days after operation, the only instance in which ligation was performed instead of thyroidectomy. The preliminary injection which Lathrop now uses is morphine, $\frac{1}{2}$ grain; paraldehyde, 2 fluid drachms; and $\frac{1}{2}$ oz. of ether with the same amount of olive oil. This mixture is given forty minutes before operation. Lathrop finds paraldehyde superior to chloroform. He describes the special technique in full, and notes that to Gwathmey of New York belongs the credit of working out the scheme of oil-ether colonic anaesthesia.

13. The Treatment of Laryngeal Tuberculosis.

DISCUSSING the respective merits of operative and conservative treatment of laryngeal tuberculosis, T. BEGIRUP-HANSEN (*Ugeskrift for Læger*, September 23rd, 1915) suggests that the laryngologist is apt to take too narrow a view of the disease, and to forget that the ultimate fate of the patient in most cases depends on the pulmonary tuberculosis which is almost invariably associated with laryngeal tuberculosis. During the last two years the author has observed, at the Silkeborg Sanatorium, 63 cases of laryngeal tuberculosis the diagnosis of which was based on ulceration, infiltration, and granulation. Only in 2 cases was the laryngeal disease a more important factor than the pulmonary disease. In 55 cases the pulmonary disease was in the third, and in 8 cases it was in the second stage. In 21 cases in which the laryngeal disease was for the most part severe the patients were much debilitated and febrile. The treatment of the laryngeal condition could therefore be only palliative, and the only operative treatment was an occasional amputation of the epiglottis for dysphagia or an injection of alcohol into the laryngeal nerves. Both these measures can, however, be undertaken by the physician with some knowledge of laryngology. In 29 cases of slight laryngeal disease, that is, limited infiltration and superficial ulceration, the course of the laryngeal disease ran parallel with that of the pulmonary disease; and the only treatment necessary, in addition to sanatorium treatment, was the local application of menthol and lactic acid. Among the remaining 13 cases there were four in which the steadily progressive pulmonary disease was associated with extensive laryngeal disease, for which energetic operative treatment might have been beneficial locally. But the author confined the treatment to the application of menthol and lactic acid, as he foresaw the patients would die in any case. In the nine other cases there was no improvement in the laryngeal disease, although there was a steady improvement in the pulmonary disease. But when more energetic measures were adopted, including the use of the galvanocautery and the curette, there was, on the whole, an improvement in the laryngeal condition. With this experience the author concludes that radical operative treatment should be confined to a very few cases, and should be undertaken only when the condition of the lungs is not hopeless. He has seen several cases in which a too active treatment of the larynx has been detrimental to the lungs and the patient's general health. Within the last few years he has seen three advanced cases of laryngeal tuberculosis greatly benefited by an artificial pneumothorax, the ulcerations in two cases healing completely.

PATHOLOGY.

14. Typhoid Spine.

RUGH (*Amer. Journ. of Orthopaedic Surgery*, October, 1915) reports a case of typhoid spine with autopsy findings, this being the first recorded pathological report upon such a condition. The disease extended over a period of six or seven years. The patient, a woman aged 32, during delirium jumped from a third-floor window on to a cement sidewalk, suffering concussion of the brain, fracture of the right acetabulum, tearing of the ligaments of the right knee, and compound fracture of the right os

calcis. Four and a-half weeks later pain first appeared in the spine and grew gradually worse until at the end of four months a slight prominence of the lumbar vertebrae was noticed. About twice a year abscesses formed about the right hip until her death, nearly eight years later, and cultures from the pus were negative until the last abscess nine months before death, when it yielded a pure culture of the typhoid bacillus. At the *post-mortem* examination it was found that the intervertebral disc between the third and fourth lumbar vertebrae was missing and was replaced by a bony overgrowth closely resembling grossly the bony tissues of the vertebral bodies. Microscopically there was complete absence of cartilaginous tissue which was replaced by dense connective tissue having a rich blood supply, and bridging the space normally occupied by the intervertebral disc. Cultures from the spleen were sterile, and those from the gall bladder were negative for the typhoid bacillus, but contained a pure culture of the *Bacillus coli communis*. The inflammation involved the intervertebral disc rather than the bodies of the vertebrae, and was of a more or less destructive character, though probably it was considerably influenced by the fixation treatment employed.

15. Non-infectious Bone Atrophy.

GREY AND CARR (*Johns Hopkins Hosp. Bull.*, November, 1915) have published an experimental study on the factors responsible for non-infectious bone atrophy. The experiments were conducted on thirty-eight rabbits and nine dogs. In both series of animals the bones entering into the formation of the ankle and wrist joints proved to be the most suitable for such a study. Structural changes in the cortex and medulla were followed by means of Roentgen rays. The limb opposite that which was experimented upon was used as a control. As frequent examinations were made in each case it was possible to follow closely the appearance and the progress of atrophic changes. Grey and Carr have arrived at the following conclusions: (1) A destruction of the sensory nerves to a part occasions no direct local atrophy of bone. A destruction of the motor nerves, on the other hand, leads to a certain amount of atrophy. This, however, is indirectly the result of inactivity or disuse, and is directly proportional to the degree of paralysis present to the part. (2) Local venous congestion leads directly to no recognizable changes in the structure of bone. Local anaemia due to injuries of the arterial supply, except in an extreme degree, likewise occasions in bone atrophy so long as the part remains functionally active. (3) Inactivity atrophy may appear very soon after immobilization of a limb as early as the fourth or fifth day in rabbits. It is probably due to a decrease or to an absence of the functional stimuli necessary to the normal nutrition of bone. (4) Immobilization retards the process of repair in bone injuries.

16. Haemophilia Calcipriva.

Hess (*Johns Hopkins Hosp. Bull.*, November, 1915) investigated a sporadic case of haemophilia in a Jewish child 6 years of age. No other member of his family was a "bleeder." He was also subject to ichthyosis, though there was not, as is usual, any family history. The investigations were extended to a boy aged 9 subject to typical hereditary haemophilia. Hess notes that this typical hereditary bleeding was not associated with a deficiency of calcium. As other investigators have shown, Hess found that the addition of calcium to the blood *in vitro* delayed rather than hastened coagulation. A deficiency could not be established by quantitative determinations of the calcium in the blood, and a metabolism study showed that the exchange of lime salts, as well as of numerous other inorganic and organic substances, differed in no way from normal. The typical instance, though sporadic, had all the other symptoms of classical haemophilia, and so could not be considered to be a case of purpura. The patient showed a definite deficiency of the calcium in the blood from a functional point of view, the addition of a weak solution of calcium markedly hastening the clotting of the blood. Quantitative determinations of blood calcium also showed a deficiency compared with the normal. A study of the boy's general metabolism further detected a negative balance of lime, which became positive when lime salts were added to the diet. Thus the sporadic case seemed to be a distinct type of the disorder—an instance of haemophilia calcipriva. Hess doubted if haemophilia were an absolute entity, if disorders were included under that name where delayed clotting of the blood, a normal number of platelets and a negative "capillary resistance test" were all present.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

17. Cardiac Insufficiency.

BARRINGER AND TESCHNER (*Arch. of Int. Med.*, November 15th, 1915) discuss the treatment of cardiac insufficiency by a new method of exercise with dumb-bells and bars, utilizing the circulatory reaction to exercise as a test of the heart's functional capacity. With dumb bells weighing from 3 to 25 lb. each and steel bars varying from 10 lb. upwards in weight it is possible to measure approximately the number of foot-pounds of work performed in each exercise. In treating patients the routine followed consisted in giving 50 to 100 foot-pounds of work with a pair of 5 lb. dumb-bells by pushing them alternately above the head, the pulse and blood pressure being taken before and every minute after the exercises. If they showed a normal type of reaction (that is, the systolic blood pressure becoming raised and the pulse accelerated, but both then rapidly falling to and below the figures noted before work began) in a few minutes another piece of work was given, increased by 50 or 100 foot-pounds through using heavier dumb-bells. By this means sooner or later an amount of work was reached which was followed by a delayed rise in blood pressure, thus showing that the functional capacity of the patient's heart had been exceeded. Many patients showed a cardiac efficiency of only a few hundred foot-pounds, contrasting strikingly with the efficiency of a normal heart, which may measure as much as 7,000 foot-pounds performed in two minutes. Having found in a given patient the number of foot-pounds which produced a delayed rise in blood pressure the daily exercise for the next seven days was limited to 100 foot-pounds less, this being given each day from four to six times with five to ten minutes' rest in between. At the end of the seven days the heart's functional capacity was again tested, and if it had increased, the work of the following week was kept just below the amount which produced a delayed reaction. As the cardiac efficiency increased various other exercises were added to the initial one of pushing the dumb-bells above the head, exercises which utilized the trunk muscles and increased the number of foot-pounds performed without tiring excessively any one group of muscles. It was found that one week's training of a normal person increased markedly the quantity of work he could do before a delayed reaction was produced. The cases selected for treatment were ambulatory patients with chronic valvular or myocardial disease and varying stages of decompensation, any acute process, history of recent emboli, or persistently high blood pressure being considered a contraindication for the exercise treatment. Nine of the thirteen patients treated showed marked improvement, apparently due to the exercises, for, with one exception, no other treatment was given, and three of those who did not improve suffered from mitral disease with marked decompensation and very low initial cardiac and respiratory capacities. The chief feature of the exercises is their concentration, each series of movements lasting from 30 to 120 seconds, followed by a rest of from five to ten minutes. By spreading the same amount of work over from ten to fifteen minutes, so that the patient does the same amount of foot-pounds in a longer period of time, a much slighter effect on the pulse and blood pressure is produced. Although the number of cases treated is small this system of exercises is a valuable adjunct to existing measures for treating cardiac insufficiency, and the validity of the post-exercise blood pressure test of the heart's functional capacity is established.

18. Acute Raynaud's Disease with Paralysis.

AMONG the victims of the earthquake in the Abruzzi on January 13th, 1915, a number of cases of paralysis of the limbs, combined with trophic lesions resembling those of Raynaud's disease, were admitted to hospitals at Rome. R. ALESSANDRI and G. MINGAZZINI (*Il Policlinico*, Rome, 1915, xxii, sez. med., 433) give an account of eighteen of these, divided into three classes, in accordance with their severity, as fatal, grave, or mild. The fatal cases were six in number, the patients were aged from 17 to 32, and had remained buried under fallen masonry for from thirty-six to seventy-two hours; the paralysis was segmental in type, and with or without pain and disturbances of sensation; the Raynaud's disease took the form of cyanosis, oedema, bullae containing blood-stained fluid, and the super-

vention in three cases of gangrene demanding amputation of an arm or a leg, or of both. Three of the patients died of adynamia cordis in two, five, and six days respectively. The second group—the grave cases—contained three patients, who had lain exposed in the ruins for from thirty-six to seventy-two hours, and were aged 16, 18, and 37 respectively. Gangrene supervened in each case, and amputation of a leg was performed in two, while the third patient, who had been buried face downwards with her arms crossed under her chest for thirty-six hours, had both forearms amputated at the proximal third a fortnight later. These patients all exhibited segmental areas of hypoaesthesia or anaesthesia, and in two the paralysis was also segmental in type; the third patient, an alcoholic man, exhibited tenderness of the sciatic and popliteal nerve trunks. The remaining nine cases were classed as mild, and were mostly females aged from 14 to 50, who had been exposed under the ruins for from eight to seventy-two hours; some had suffered trauma, others from the cold. Here the Raynaud's symptoms had not gone beyond the stage of asphyxia as a rule, though bullae and necrotic patches appeared in a few instances. In general the legs were more involved than the arms; in a few cases there was marked and very acute neuritis of certain nerve trunks (ulnar, median, radial, superficial peroneal, sciatic, lateral popliteal, crural) with the characteristic distribution of paralysis, anaesthesia, and trophic changes (that is, Raynaud's symptoms). In the first group—the fatal cases—the stocking-and-glove distribution of the nervous lesions indicated a "functional" or "hysterical" type of origin; in some of these patients examination of the nerves of an amputated leg showed no abnormality of the nerve fibres. The arteries of the amputated limbs in two other cases showed no abnormality, but were thrombosed in a third patient. Discussing the pathogenesis of this acute form of Raynaud's disease with paralysis, the authors connect it with the severe psychical shock caused by the earthquake. The patients in the first two groups showed rapid pulse and abnormally low blood pressure, and it is assumed that the Raynaud's symptoms were due to shock to the vasomotor system. Even in the mild cases with evidence of peripheral neuritis this factor probably was involved, as the Raynaud's symptoms disappeared before the evidence of neuritis. The authors can draw no very definite conclusions as to the way in which the trophic and vasomotor nervous systems were upset by the earthquake; they quote Cassirer's views on the question. They note that all their patients had been exposed to cold and to mechanical obstruction of the circulation by pressure, as well as to psychical shock. They argue that the adynamia cordis from which three of their patients succumbed was due to sympathetic vaso-constriction of the coronary arteries.

SURGERY.

III. Surgical Treatment of Gastric Crises in Tabes.

GEORGES PATRY (*Revue médicale de la Suisse Romande*, June 20th, 1915) deals with the surgical treatment of gastric crises and describes a case treated by himself by Guleke's modification of Förster's operation. The two predominant symptoms in gastric crises are pain and vomiting, and, according as the greater importance attaches to the pains or the vomiting, so the nerve chiefly implicated is the splanchnic or the vagus. Förster attaches the chief rôle to the sympathetic nerve, on the grounds that (1) the pain is the dominant factor, is the earlier symptom to appear, and is of longer continuance than the vomiting; (2) the origins of the splanchnic are in intimate relation with the intercostal nerves, and therefore the existence of the zones of anaesthesia or hyperaesthesia, frequently present in the epigastric region, is readily explicable on this hypothesis. Moreover, the pains are not confined to the stomach, and the presence of girdle pains localizes the lesions to the posterior roots corresponding to the rami communicantes which give origin to the great splanchnic. On this theory the vomiting is due to secondary reflex action. These clinical

facts are supported by the anatomical conclusions of J.-C. Roux, and more recently by those of Tinel. According to these workers the primary lesion is a posterior root lesion. The roots are found to be surrounded by masses of leucocytes, and there is a great excess of fibrous tissue. This lesion causes irritation both of the intercostal nerves and the sensory fibres from the splanchnic which reach the cord by way of the posterior roots. The object of the majority of recent operations has therefore been to interrupt the nervous conductivity above the irritative lesion. Exner alone attacks the pneumogastric nerve. He performs a double vagotomy, reaching the nerves through an incision above the umbilicus, and at the same time performs a gastro-enterostomy to combat any danger of future disturbance of gastric motility. Of 6 cases treated by Exner himself 3 only were benefited. Kuttner performed Exner's operation in a case already treated on Förster method in which the crises had ceased after the first operation but vomiting had persisted, but he found the vomiting much aggravated after the vagotomy. Förster ascribes the failure of double vagotomy to improve the motor lesions to the section being below the irritative lesion, and proposes in cases in which vomiting persists after radicectomy, to attack the jugular ganglion; in spite of the difficulties of technique, Kuttner has finally performed this operation with success. Förster and Kuttner's operation upon the posterior roots is carried out as follows: A laminectomy is performed at the level of the roots; these are resected to the length of about 1 cm., and the dura mater and the more superficial layers of the wound are carefully closed. The difficulties and complications of the operation may be considerable. To avoid the danger of shock it has been proposed to perform it in two parts, the preliminary laminectomy being performed on the first day and the opening of the dura mater and resection of the nerve roots a few days later. This method has, however, the great disadvantage that where clear vision is of the greatest importance, the field of operation is obscured by the presence of clots, and it should therefore be reserved for patients in an advanced state of cachexia. To avoid haemorrhage, which may be a serious complication, the cutaneous incision should be exactly in the middle line and the muscles should be rasped near to the bone, instead of being cut. Moreover, as soon as the laminae have been separated, the wound should be plugged for from five to ten minutes with hot wet compresses. Another frequent complication is the escape of cerebro-spinal fluid, which may not only obscure the operative field, and also even cause immediate fatal results, but may in other cases lead to the formation of a fistula with all the chances of infection of the meninges. To prevent it the patient should be placed with the head hanging down, and Debrey recommends that the spinal canal should also be plugged above and below. In Guleke's modification of Förster's operation the dura mater is not opened. Guleke separates the anterior and posterior roots, which may be differentiated from one another by their differing volume, the anterior root being about twice as thick as the posterior, and then resects the posterior root. This operation has the reputation of being a difficult one to perform, but the author employed it in the case he himself treated and found it easy. Another modification of Förster's operation is Fränke's method of attempting to reach the ganglion and the root without laminectomy by tearing the intercostal nerves. According to Sauvé and Tinel, the tearing of the nerves must be rough, not slow and progressive, in order to bring about a profound disturbance of the coils of origin. The author sees no reason to prefer the uncertain method of Fränke to the operations which directly attack the posterior roots, but Sauvé and Tinel's modified operation is worthy of trial. Of 13 cases treated by Fränke's method, 2 died as the result of the operation, 2 had immediate and 3 speedy relapses, 5 were dismissed from the clinic as cured, but were not followed up; 1 only was known to have remained eleven months without a relapse, and could be considered as cured. Gambier has collected records of 60 cases of Förster's operation or its modifications by Guleke, Sicard, and Dumarest; with the author's own case the total number is thus 61. Of these, 19 died, 2 of independent illnesses, the remainder as a result of the operation. Of the remaining 42, in 2 the crises were more severe after the operation, in 1 they were not influenced, in 2 they were slightly improved, in 5 the crises disappeared for a time but afterwards recurred, and in 1 (the author's) the condition was improved, but the patient was lost sight of; in 4 crises persisted, but were less severe; in 27 there was so great improvement that it might almost be regarded as a cure. Thus the results were: Deaths, 31.1 per cent.; unfavourable, 16.4 per cent.; good, 52.5 per cent. These results are not brilliant, but,

considering the previous hopelessness of the condition, they constitute real progress, and, in the author's opinion, it is infinitely preferable to run the risk of an operation than to leave the crises untreated. He considers Guleke's operation to be the best.

20. Traumatic Paralysis of Brachial Plexus without Fracture or Dislocation.

LEVISON (*Hospitalstidende*, September 8th, 1915) records the case of a workman, aged 34, who was a moderate drinker and had hitherto been well. Falling from a load of straw on to a stone, he struck his shoulder in trying to hold himself with his left hand. He was put to bed and fell asleep, but next day he noticed that his left arm was paralysed, swollen, and anaesthetic. On his admission to hospital, complete paralysis of the left arm, as well as anaesthesia of the hand, of the forearm, and of most of the outer side of the upper arm, were found. The arm was swollen, and the skin of the thumb gangrenous, and the reaction to degeneration was noticeable a week later. The fact that even the most careful examination did not disclose a fracture or dislocation was a most extraordinary feature of this case, in view of the completeness of the paralysis. The author assumes that the cause of the paralysis must have been a haemorrhage into the plexus itself, a view which was confirmed by the shortness of the interval between the accident and the development of the paralysis. Though the sensory disturbances were less, the paralysis was as complete as ever two months after the fall. The atrophy was most evident in the deltoid and in the supra- and infra-spinatus muscles. The paralysis affected the three main branches of the brachial plexus, as well as the musculo-cutaneous, axillaris, and supra-scapular nerves. The nerves to the rhomboids, to the pectoralis major and minor, as well as the subscapularis had escaped injury, in spite of the origin of the latter from the plexus being below that of the subscapularis, which was paralysed. It was proved by x-ray photographs of the diaphragm, instillation of adrenalin and cocaine into the eye, and the administration of pilocarpine, that the phrenic and sympathetic nerves were uninjured.

21. Limitations of the X Ray.

COTTON (*Amer. Journ. of Orthopaedic Surgery*, October, 1915) discusses the limitations of the x ray in the diagnosis of certain bone and joint diseases. While the x ray is invaluable as an aid in the diagnosis of many bone and joint conditions, and the roentgenogram is pathognomonic of some diseases, there are different diseases in which the roentgenograms are similar, and the diagnosis must therefore be made with the aid of clinical data. In the early diagnosis of certain pathological conditions of bones and joints—for example, tuberculosis and acute infectious osteomyelitis—the x ray is not of great value, because of the fact that changes in the structure and in the density of the bone have not been produced, and further the x ray cannot be relied upon always to give a true picture of the nature and extent of the pathological process. These limitations of the x ray in the diagnosis of diseases and extent of pathological processes are due to the fact that the roentgenogram does not show differences in the composition of substances of the same density.

OBSTETRICS.

22. Management of Placental Stage of Labour.

POLAK (*Surgery, Gynaecology, and Obstetrics*, November, 1915) strongly objects to any disturbance of the normal mechanism of the separation of the placenta. It will come away spontaneously if the normal mechanism be not impeded—by manipulation, for instance, of the uterus before the clinical evidences of separation are apparent. *Post-partum* haemorrhage is best avoided by respecting the physiological processes, while manipulation causes partial detachment and predisposes to flooding. The normal mechanism of placental delivery is that described by Schultze, and the Duncan mechanism only occurs in low implantation of the placenta and when untimely and vigorous manipulation has been practised. The placenta may be retained in the uterus for hours or days provided that it be attached or completely detached, which ensures that the bleeding will be negligible. Sepsis is dependent on penetration of the uterus by the hand or instrument through infected passages and not upon retention of the placenta. Manual extraction is only admissible in partial separation with haemorrhage. In retention without haemorrhage the cord should be cut off close to the cervix and the case watched until the signs of separation are

apparent, when the placenta may be expressed by Credé's method under anaesthesia. Invasion of the uterus through the vagina is fraught with danger from infection, and on exploration, should the placenta not be found presenting at the internal os, intrapelvic delivery should not be attempted, and the fetus should be extracted through sterile avenues by suprapubic extraperitoneal hysterotomy. When the adhesion is so great that its removal entails the digging out piecemeal of the placenta, then excision of the placental site or hysterectomy is demanded.

23. The Relation of Menstruation to Conception.

WITH a view to applying the peculiar conditions of the war to the study of the problems of conception, P. W. SIEGEL (*Deut. med. Woch.*, October 14th, 1915) has investigated the relation of menstruation to conception among pregnant women whose husbands had been mobilized. He assumed that when, for example, a married woman menstruated last on July 31st, 1914, and when her husband left her on August 6th for active service, and did not return to her till pregnancy was well advanced, it followed that conception had occurred between July 31st and August 6th. Similar opportunities for fixing the date of conception with considerable accuracy were given when a husband's leave at home lasted only two to eight days. At the Gynaecological Hospital of the University of Freiburg the author questioned 100 married women who had become pregnant under the mentioned conditions. He did not attempt to find out the dates on which coitus had actually taken place, and he confined his inquiries to the date of the last menstruation and of the husband's leave at this period. In all these cases the fruitful coitus could only have occurred within the first twenty-one days after the last menstruation. The author shows by a table that conception was most frequent on the sixth day after the beginning of the menstruation. From this day to the twelfth or thirteenth day after the beginning of menstruation the incidence of conception remained at a high level, but from the thirteenth to the twenty-first day it showed an abrupt fall, and from the twenty-first day onwards complete sterility supervened. The fall in the curve between the thirteenth and twenty-first day would probably have been still more abrupt had not the statistics included cases in which the husband lived with his wife from the tenth to the twenty-first day after the beginning of menstruation. In ten cases the husband's leave extended only from the twenty-second to the twenty-eighth day after the beginning of menstruation, and in none of these cases did conception occur. The author refers to another series of observations made during the last ten years at the Freiburg Gynaecological Hospital by Wohlers, who has collected all the cases of conception which had occurred within the first five weeks of marriage. He found only 160 primiparae fulfil this condition. In about 65 of these cases the marriage had been celebrated within the last eight days before the beginning of menstruation. In every one of these cases there was only one menstrual period before conception occurred. These cases, and the ten cases observed by the author, show that conception during the last eight days before the beginning of menstruation is a very improbable, not to say impossible, event.

GYNAECOLOGY.

24. Fatal Septicaemia Due to an Intrauterine Pessary.

To illustrate the dangers of the intrauterine pessary, and to warn his colleagues against their use, BRANDT (*Norsk Magazin for Laegevidenskaben*, October, 1915) records the case of a married woman, aged 43, who had undergone five normal confinements, and who had worn an intrauterine pessary for the past six years. It had been changed every six months by a medical man, the last change having been made three months before her admission to hospital. A fortnight before admission she began to suffer from rigors and headache but no abdominal pain. Later she became drowsy and deaf, and suffered from coughing and vomiting. On admission she was drowsy and deaf, the temperature was 40° C., the pulse was 136, and the respirations 40. The urine contained neither pus nor albumin. The lower abdomen was somewhat tender, as was also the uterus on bimanual examination. There was, however, no distension of the pelvic organs. The intrauterine pessary was removed, fomentations were applied, and morphine was given. Two days later she died, and the diagnosis of septicaemia was confirmed by the necropsy, which showed

endometritis, enlargement of the spleen, and parenchymatous degeneration of the internal organs. The pessary consisted of two thin springs secured to a plate. It was constructed so that when the springs were brought together and inserted into the uterus their outward pressure kept the pessary in place. In addition to preventing conception, which is its primary object, it irritates the lining of the uterus and provokes a more or less severe endometritis—in its turn a further hindrance to conception. The pressure exerted by the springs ultimately induces necrosis of the tissues in contact with them, and thus opens a channel to infection. The author has removed three similar pessaries from patients in whom they had provoked serious disease. In one case pyaemia and in two cases severe pelvic peritonitis were the sequel to this malpractice. All three patients recovered after a long illness. The author points out that the extensive misuse of this pessary in Germany has already provoked official condemnation from the Government, and the gynaecological societies. Owing to its use as an abortifacient as well as a preventive of conception its suppression by law has recently been mooted. Unfortunately this pessary has been popularized also in Norway, where the author has found it in use in country districts as well as in towns.

25. Hydatidiform Mole: Chorion-epithelioma: Bilateral Corpus Lutein Cyst.

FORD (*Amer. Journ. Obstet.*, August, 1915) reports an instance where these three pathological conditions followed each other in a very significant manner. A woman, aged 20, began to bleed in the fourth month of her first pregnancy, then the abdomen increased in size, and at the end of a week she seemed to have reached term. Under anaesthesia about a quart of hydatidiform cysts was removed and the uterus packed with plain gauze. Three weeks later the uterus had not undergone involution and haemorrhages continued; the curettings showed decidual reaction in strips of compact decidua, large masses of decidual cells surrounded by fibrous masses, and a small amount of trophoblast. Within five weeks after delivery of the mole the uterus and appendages were removed. The uterus was uniformly enlarged and the mucosa of the fundus showed large masses of syncytial cells invading the myometrium. Numerous syncytial giant cells were detected, isolated between the muscular fibres. Both ovaries were cystic and of about the size of a fist. The right ovary contained a clear serous fluid, the left held 500 c.c.m. of a highly albuminous fluid, clotting to a certain extent and mixed with small old blood clots; at one point on the cyst wall was a minute body, apparently a fairly fresh corpus luteum. On microscopic examination markedly hyperplastic lutein cells were detected in the cyst walls of both ovarian tumours. In a discussion on this case before a society there was difference of opinion expressed as to the causal relation of a mole and a lutein cyst. Vineberg noted that, according to trustworthy recent statistics, 16 per cent. of hydatidiform moles became chorion-epithelioma, and 50 per cent. of chorion-epitheliomas were preceded by hydatidiform moles.

THERAPEUTICS.

26. Typhoid Vaccination.

C. D. HAMILTON (*Journ. Amer. Med. Assoc.*, November 27th, 1915) says that since 1908 it has been observed that a positive Widal reaction always followed a prophylactic dose of typhoid vaccine. While it was now believed that this was not necessary for immunity, but that the patient might still be immune after the reaction had ceased, the presence of the reaction was of the greatest importance if typhoid was suspected. Since 1910, at the Springfield State Hospital, there had been 2,766 prophylactic doses of typhoid vaccine given, and at intervals the Widal test had been made. During the first eighteen months after the vaccination was adopted each patient received three doses at intervals of one week. Only the blood of patients who could give a clear history of never having had typhoid fever was examined. "Blood was taken from patients at the end of one month, six months, twelve months, twenty-four months, thirty-six months, and forty-eight months respectively, with the following results:—One month: ten specimens of blood all gave positive Widal reactions. Six months: ten specimens of blood all gave positive Widal reactions. Twelve months: ten specimens of blood all gave positive Widal reactions. Twenty-four months: ten specimens of blood gave seven positive and three negative Widal reactions. Thirty-six months: ten specimens of

blood gave six positive and four negative Widal reactions. Forty-eight months: ten specimens of blood gave three positive and seven negative Widal reactions. One patient inoculated fifty months ago still had a positive Widal reaction." Hamilton concludes that a positive reaction in any one who has ever been inoculated with antityphoid vaccine is of no value in diagnosing typhoid fever, and the only reliable means of ascertaining the cause of continued fever suspected to be typhoid is by the blood culture and leucocyte count.

27. Treatment of Gonorrhoea with Optoquin.

The failure of the ordinary antigonorrhoeal drugs in many cases led LEVY (*Berl. klin. Woch.*, October 18th, 1915) to try optoquin, which he gave in 25 cases of gonorrhoea. He was greatly impressed by the efficacy of this drug, which he injected six times a day, the strength of the solution being 1 per cent. Apart from a slight burning sensation, the injection caused no discomfort. Indeed, pain which had previously been troublesome on micturition soon ceased after the injections were begun, and the anaesthetic action of optoquin observed in cases of ulcer serpens of the eye is evidently, therefore, not confined to the eye. A further effect of the drug on the gonorrhoea was the marked diminution of the discharge, which quickly lost its purulent character, and became watery and transparent. Gonococci, which had previously been numerous, rapidly decreased in number, and were difficult to find after the injections had been given for four days. In no case did this treatment provoke complications. Some of the cases were acute, and had not previously been treated in any way. Other cases were chronic, and had undergone the most varied forms of treatment. The chronic cases reacted more satisfactorily to optoquin than the acute cases. In some cases the treatment with optoquin alone was inadequate, and though the discharge diminished and lost its purulent character, and though the gonococci disappeared almost completely, yet there was a little discharge in the morning from the urethra, and the first morning specimen of urine still contained threads. Cases in which an eight days' course of treatment with optoquin failed to effect a complete cure were subsequently treated with protargol, which in a short time completed the cure. One patient was a girl, aged 10 years, who suffered from acute gonorrhoea, and whose profuse discharge contained numerous gonococci. After three days' treatment with optoquin the discharge had diminished much and the number of gonococci was much reduced. After eight days the discharge had completely disappeared and gonococci were no longer demonstrable. A second patient was a non-commissioned officer who had been infected four days earlier, and who had suffered for a day from a profuse discharge which contained numerous gonococci. After two days of the treatment both the discharge and the number of the gonococci were much reduced. On the fourth day there was no longer any discharge but the urine passed in the morning still contained a few threads. A third patient was a young man who had been treated for four weeks by the author with strong solutions of protargol, which had failed to cure the gonorrhoea. After eight days' treatment with optoquin a complete cure was effected.

28. Treatment of Syphilis with Salvarsan Only.

R. KREFTING (*Deut. med. Woch.*, August 12th, 1915) disapproves of the present system of combining mercury with salvarsan in the treatment of syphilis. This blunderbuss pharmacy is the result of the mistakes made in the early days of salvarsan, when unbounded faith in the drug was rapidly followed by failures and accidents. Even Ehrlich had not the courage of his convictions and consented to this polypharmacy. Since 1910 the author has given 3,200 intravenous injections of salvarsan, the treatment, with only three exceptions, being ambulatory. Though his dosage was, as a rule, high, he never provoked alarming symptoms, and, with only very few exceptions, his patients were again fit for work on the day after an injection. The interval between each injection was seldom less than fourteen days. In no case did he observe true idiosyncrasy to the drug, but a few patients developed a scarlatiniform rash after an injection. In 4 cases of secondary syphilis he observed the so-called "nevrorezidiv," but this condition was only transitory, disappearing when the salvarsan was pushed. These nervous phenomena were, in his opinion, undoubtedly syphilitic. Of his 718 patients, 218 were suffering from primary syphilis when the treatment was instituted. Of these, again, 70 were given only one to two injections each,

while 148 were given at least three injections. The dosage was 0.5 to 0.6 gram for a man of normal weight, and 0.3 to 0.4 gram for a woman. In one group of 84 cases, in which Wassermann's reaction was negative, the disease was apparently cured, and in no case was a relapse observed. In another group of 61 cases, in which Wassermann's reaction was positive, the treatment was not followed by a single relapse. But there were 3 other cases in which slight relapses followed. Thus, in a total of 148 cases, in all of which at least three injections were given, there were only three relapses. Among the 70 patients who were given only one or two injections only four relapses were observed. The author found neo-salvarsan less potent and less capable of affecting Wassermann's reaction than salvarsan. Further proof of the curative effect of salvarsan alone was the fact that 10 of his patients were reinfected with syphilis. He concludes that salvarsan alone is quite as effective as a combination of salvarsan with mercury; and that in the early stages of the disease salvarsan alone, properly administered, almost invariably effects a radical cure. In secondary syphilis, however, salvarsan must be given for a long time, and must be continued even after Wassermann's reaction has become negative.

PATHOLOGY.

29. The Bordet-Gengou Test in Echinococcal Infections.

AFTER a long and detailed account of the various biological tests that have been employed for the diagnosis of echinococcal cysts in the human body, L. C. ZAPPELLONI (*Il Policlinico*, Rome, 1915, sez. chirurg., xxi) draws the following conclusions, supporting them in many instances by references to the extensive literature of the subject. The Bordet-Gengou test gave a positive result in 55 of his own 58 cases, and in 88 per cent. of 535 cases of echinococcal cyst collected from the literature. Positive reactions are obtained, apparently, indifferently in the common cases of infection by *Echinococcus hydatidosus* and the rare cases of *E. multilocularis*, as if these two varieties of echinococcal cysts were really but a single species. If the test fails to give a positive result, probably this is due to faulty technique in most cases, though not in all; it appears that in exceptional instances suppuration or calcification of a hydatid cyst may result in the disappearance of echinococcal antibodies from the circulating blood. On the other hand, a good many cases have been recorded by various authors in which a positive result was obtained in patients free from echinococcal infection; here again a faulty technique is generally responsible. Zappelloni concludes that in at least 6 cases, 2 of them his own, an erroneous positive reaction was obtained with an apparently faultless technique; he leaves these instances unexplained. He finds at least 1,600 instances in the literature in which patients apparently free from echinococcal infection gave a negative Bordet-Gengou reaction; and notes that the reaction usually remains positive for at least a month after the operative treatment of one of these cysts. As is well known, the blood of patients with echinococcal cysts usually shows eosinophilia; but this is observed in only 60 per cent. of the cases, and is also often present in a score of other diseases. The eosinophile cells form from 3 to 68 per cent. of the leucocytes, and their number varies widely from time to time in any given patient; hence, as Zappelloni points out, and as has often been stated by previous writers, eosinophilia is practically useless in the diagnosis of hydatid disease. The presence of a precipitin reaction in the blood is equally valueless here; and so is the meiostagmin reaction; the anaphylactic reaction (that is, the analogue of von Pirquet's or Calmette's tuberculin reaction) has proved a failure likewise. Zappelloni has studied the Bordet-Gengou reaction in hydatid disease for five years, and has examined the blood of 114 patients with the infection and 167 without it. He lays great stress on the employment of a proper technique, mentioning eight points of special importance that cannot be dealt with here but should be studied by all who have to apply the test in practice. The specific antibodies occur in the serum of practically all patients with hydatid cysts anywhere in their bodies; if the cyst is in the central nervous system the cerebro-spinal fluid also will contain these antibodies, otherwise it does not. The antibodies are not present in the patients' urine, or in pleural or peritoneal exudates.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

War Number.

MEDICINE.

30. Scarlet Fever in the French Army.

At a meeting of the Réunion des Médecins de la IV^e Armée held on December 3rd, 1915 (*Paris méd.*, January 1st, 1916), FELIX RAMOND and GUSTAVE CHAMBAS read a communication on scarlet fever in the Fourth Army. From their own experience they were able to confirm the statement of the Swedish professor, C. Kling, as to the relative rarity and benignity of infectious diseases at the French front. They had treated 131 cases in nine months; all ended in recovery. Treatment consisted of the usual hygiene and diet, with sodium salicylate in doses of 3 to 6 grams daily, given for the reduction of the fever. Rheumatism occurred as a complication in 29 per cent. of the cases, and jaundice in 8 per cent. The rheumatism, which was not serious, presented the characters described by Trousseau; there was neither effusion nor oedematous redness round the joints, only pain about the insertion of the ligaments, and often in the periarticular muscles. Not many joints were affected; the knee and shoulder were most frequently attacked. The onset was sudden, the evolution rapid, and resolution was complete. The salicylate had an evident effect on the infection, and was well borne. On the other hand, antistreptococcic serum was useless. The jaundice, which in half the cases of rheumatism was a concomitant, was slight, lasting generally only ten to twelve days, and did not increase the gravity of the prognosis. MERKLEN, from his experience, agreed as to the frequency of rheumatism in men suffering from scarlet fever last summer, and its frequent association with transient disturbances in the rhythm and tone of the heart sounds. Scarlatinal albuminuria, having nothing to do with renal sclerosis, but due to slight acute simple nephritis, did not contraindicate the use of salicylate.

31. The Pulse in Scarlet Fever.

At a meeting of the Société Médicale des Hôpitaux on October 22nd, 1915 (*Paris méd.*, November 27th, 1915), NOBÉCOURT reported nine observations of scarlet fever, showing the frequency of tachycardia in convalescence from that disease. The acceleration of the pulse might be noted thirty to forty days after the disappearance of the eruption. This fact, he said, had a certain interest for the army medical officer called on to give an opinion as to the probable duration of convalescence in scarlatinal patients.

32. Nephritis in Soldiers in the Field.

At a meeting of the Académie des Sciences on November 8th, 1915 (*Paris méd.*, November 27th, 1915), PIERRE MARIE read, on behalf of G. PARISOT and F. AMEUILLE, a paper on certain acute forms of nephritis of abnormal type observed in soldiers in the field both French and British. These cases were of exceptional severity, and caused an enormous albuminuria coming on suddenly; sometimes also uraemic phenomena were observed which were all the more misleading as they coincided with a high degree of fever. They were certainly of toxic origin, although they could not be confounded with fatigue albuminuria. They were perhaps due to too carnivorous a diet, to insufficiency of diuretic beverages, and to immobility in the trench. Parisot and Ameuille drew two practical conclusions: (1) That an examination of all patients should be made systematically, and (2) that means should be found of supplying the combatant with abundance of vegetables.

SURGERY.

33. The Treatment of Septic Wounds.

THE *Polielino* (Sezione pratica, Fasc. 2, January 9th) contains a report of a discussion on the treatment of septic wounds held at Milan on November 11th in the group of medical war propaganda (Conversazioni castrensi promosse dal Gruppo di propaganda medica nella guerra). PEREZ of Pavia opened the debate by saying that as to the treatment of aseptic wounds there was general agreement. Simple protective aseptic medication, preceded by cleansing of

the skin of the part with benzine, alcohol, or tincture of iodine, with a good position of the injured limb, was sufficient to effect a cure. As for the treatment of infected wounds, while some insisted on the necessity of large incisions, opening up of tracks, free use of an antiseptic by irrigation, packing and drainage, others recommended more or less complete abstention with simple cleanliness of the part and immobilization in a convenient position. Perez thought abstention might easily be carried too far; in the treatment of war wounds the sound rules of general surgery should be adhered to. It was necessary to avoid or to reduce as far as possible the dangers to which the organism was exposed in defending itself against the processes with which the injured part had to contend. To-day the surgeon had at his disposal all the means of meeting these indications. Moist heat, favouring vasodilatation and diapedesis, hastened the natural evolution of the inflammatory process; hence very hot packs were of the greatest use, and had a sedative action on pain. Where inflammatory hypertension persisted and tended to increase, free incision was necessary in order to prevent or arrest gangrenous processes, bony necrosis, and infiltration of the cellular tissue. Moreover, such incisions, by reducing congestion of the tissues, opened up a free path for the elimination of toxic products and exudates, and obviated the risk of thrombosis consecutive to stasis in the vessels. As for circumscribed collections of pus, the best course was undoubtedly to open at the most dependent part. Perez went on to say that the abandonment of many antiseptics in the treatment of wounds was connected with the fact that many of those once considered very active not only did not possess a powerful and speedy bactericidal action, but injured the tissues, diminishing the power of defence, besides exerting a general toxic action in the organism. But if sublimate, carbolic acid, and other antiseptics were now discarded, that did not mean that antiseptics not having these drawbacks must be abandoned. Where the skin was unbroken, alcohol, either alone or in combination with iodine, was very efficacious. Among the antiseptics which might be applied to wounded tissues without disadvantage was oxygenated water, which, besides its antiseptic and oxidizing action, also promoted the clearing out of exudates and broken down tissues in the tracks and anfractuosités of wounds. There are also the preparations of iodine and chlorine. He insisted on the great efficacy of calcium hypochlorite, both on account of its antiseptic power (which it owed as much to the chlorine as to the calcium), and of the property which it possessed of destroying dead tissues without affecting living tissues. It thus exerted a very marked cleansing action on gangrenous wounds. Moreover, it was not toxic. Potassium permanganate might be very useful, especially in cases of putrid gangrenous wounds, and, owing to its very slight toxicity, had the advantage that it might be used for the prolonged immersion of limbs. In addition to local treatment it was well to use means to increase the resisting power of the organism by means of therapeutic serums and vaccines. In this way it was possible to save limbs which seemed doomed to amputation. MIRTO of Milan thought they should seek to restrain the great readiness of young surgeons to intervene for the extraction of projectiles in parts where they caused no inconvenience, and more especially for the removal of bony fragments, which if left might help the formation of osseous callus in some comminuted fractures. Disinfectants should be used only in suppurating wounds, and must be condemned when they injured cell vitality. He had got the best results from abundant irrigation of suppurating foci, which had the advantage of removing necrotic shreds and foreign bodies, and bringing the disinfectant to bear on surfaces already cleansed. For wounds he used oxygenated water and a solution of calcium hypochlorite, 3 per cent., with the addition of boric acid 4 per cent. That solution gave excellent results. The disinfecting irrigation was followed by washing with physiological solution to revive the tissues. In inflammatory infiltrations he used moist heat and packing with gauze steeped in alcohol, 60 to 70 per cent. By these methods he had treated some 250 cases of wounds without a single death or complication,

and with excellent functional result. PICCAGNONI of Busto Arsizio agreed with Perez that there was no scientific justification for the abstention now recommended in the treatment of septic wounds. It was only by seeking carefully to destroy the source of the infection by giving free exit to pus that grave consequences could be prevented. Abstentionism could be justified only if serum and vaccine therapy could be applied effectually. They were, however, still far from that consummation. A. BERTARELLI, without disputing the efficacy of sublimate as an antiseptic, could not forget the erythema and true dermatitis sometimes produced by the use even of a solution of 1 per 1,000 for washing the skin. Potassium permanganate, oxygenated water, and calcium hypochlorite, were better antiseptics and were free from disadvantages. He would like to see the use of sublimate reserved for the disinfection of things, and no longer applied to the human body. Iodoform he would also abandon on account of its irritating effects on the skin, and he would say the same thing of xeroform. PEREZ, in summing up the debate, said he recognized the efficacy of serum and vaccine therapy rationally carried out. But he believed that when the method was even in a more advanced stage than it was at present it would still be difficult, without surgical intervention, to prevent the consequences of accumulations of pus.

34. Localized Tetanus.

At a meeting of the Académie de Médecine on November 9th (*Paris méd.*, November 27th, 1915) SAMUEL POZZI reported a case of tetanus strictly limited to the wounded limb. The patient was a man who had been struck by a fragment of shell which pierced his foot, making a lacerated wound of no great size. He was dressed almost immediately, and after three days received an injection of antitetanic serum; he seemed in a fair way to recovery, but suddenly, on the fifth day, the temperature rose. He had convulsive movements of the wounded foot and the leg and thigh of the same side. The man complained of intolerable pain, which neither morphine nor other opiates nor chloral could relieve. He called loudly for amputation, and this was done, as there appeared to be no other means of saving his life. For a certain time the pain continued to be very severe; then, after some large injections of serum, it diminished in intensity. All these phenomena involved only the foot and leg of one side, only sometimes radiating to the other side. At the time of the report the patient was making an excellent recovery, the only symptom remaining being painful contraction of the leg and the thigh. The temperature had become normal and the infection had disappeared. ROUTIER said that he had had 5 cases similar to that reported by Pozzi.

35. Extract of Fragments of Projectile from the Lung.

At a meeting of the Société de Chirurgie on October 27th, (*Paris méd.*, November 27th, 1915) MAUCLAIRE discussed the indications for the extraction of projectiles embedded in the lungs. He said the surgeon must intervene if the respiratory movements caused great pain or if there were signs of a large abscess. If the projectile was deeply seated it was best not to intervene. The operative technique was facilitated by radioscopy and radiography, and by the use of Bergonié's electric vibrator. QUÉNU agreed with Mauclore, and pointed out as a contraindication of intervention the presence of a number of fragments. TUFFIER thought that some precise indication, such as the menace of a complication, should be awaited before intervention. At a meeting of the same society on November 10th, PIERRE DUVAL expressed the opinion that every foreign body in the lungs should be removed. He drew a distinction between (1) projectiles superficially or deeply seated, lodged in a piece of lung adherent to the chest wall, with or without cutaneous fistula, and (2) projectiles lodged in free lung not adherent to the thorax. In the former case the indication for operation was definite. In the second it was open to discussion, but Duval thought it was indicated, on account of symptoms which made the wounded man quite unfit for service, and in view of the possibility of a suppurating focus enveloping the projectile.

36. A Fragment of Shell in the Right Ventricle.

At a meeting of the Réunion des Médecins de la IV^e Armée on October 22nd (*Paris méd.*, November 27th, 1915) VOUELLE reported a case in which he had attempted to extract a fragment of shell from the right ventricle. On opening the thorax and pericardium, the fragment was seen lying free in the cavity, and could be seized with the fingers. Every attempt to remove the foreign body, how-

ever, was followed by alarming syncope, and the operation could not be completed. The patient died four days later of suffocation. The autopsy showed no visible lesion in endocardium.

37. Gaseous Bags as Dressings.

MORISOT (*Journ. de méd. et de chir. pratiques*, July 25th, 1915) recommends as a dressing for wounds the application of sachets or bags containing materials from which gases, especially carbonic acid gas or oxygen, will be generated and reach the wounds in the nascent state. He recommends that the outer covering of the bag should be of "tangepe," a perforated material with a mesh somewhat smaller than that of gauze, and that it should contain sterilized granulated cork. The bag will thus only touch the wound at points instead of lying wholly in contact with it, and air will circulate freely within the bag. As a dry dressing, when no gaseous element is introduced, this has an advantage over gauze in that it adheres less to the surface of the wound, and therefore cicatrization is not so much interfered with and is more rapid. In order that carbonic acid gas may be continuously in contact with the wound the cork is prepared in an acid solution, dried, and placed inside the bag, together with the desired amount of sodium bicarbonate. The addition of anhydrous sodium carbonate enables a certain quantity of heat to be generated when the bag is dipped in water, and so helps the nutrition of the tissues. When the dressing is needed for use the bag is soaked in boiled water and rapidly applied to the wound, when carbonic acid gas is slowly and continuously generated. The gas as thus produced is in no way irritating, and penetrates into all the recesses of the wound. To obtain oxygen in the nascent state, the bag should contain bicalcote, which in contact with nascent carbonic acid produces oxygen. For a dry dressing the wet bag is covered with cotton-wool, for a wet one with an impermeable covering. The advantages of this form of dressing are: (1) Cheapness; (2) simplicity of application, with no need for the preparation in advance of any solution; (3) ease of transport and of conservation; (4) non-adhesion to wound surfaces; (5) maintenance of a gaseous atmosphere round and within the wound; (6) analgesic action due to the carbonic acid and to the formation by the dressing of a tampon permitting of the support of the weight of the body. A patient with wounds of the foot, for example, no longer feels sharp pain, and can earlier begin active movements and walking.

38. Gas in the Tissues.

WOODBURN MORISON (*Archives of Radiology and Electrotherapy*, December, 1915) states that he has been able on many occasions, by x-ray examination, to demonstrate the presence of gas in the tissues in association with injuries caused by pieces of shell casing or metal with ragged edges. In all these cases the metal had carried into the tissues shreds of clothing, which were found in the track, and adherent to the ragged edges of the projectiles. The clothing of the men coming from the trenches was caked with earth in many places, and in this way anaerobic gas-forming bacilli were carried deep into the tissues. Gas was more rarely proved in wounds occurring in the face or hands and in wounds made by rifle bullets, which, with their pointed ends and smooth surfaces, carried no clothing and afforded no means of entrance to gas-forming bacilli. The author divides into two groups the cases in which gas was demonstrated: (1) True gas gangrene. Here the gas formation was exceedingly rapid, spreading along the muscle sheaths, and finally leading to complete disintegration of the muscles. The quantity of gas evolved was considerable, the part affected being swollen and so tense that the gas could be heard escaping when an incision was made. (2) Localized gas formation. Here the gas formed in the vicinity of the metal and collected in bubbles of varying size, gathering slowly and not exhibiting the same tendency to spread along the muscle sheaths. It was possible to demonstrate its presence in minute quantity long before it could be diagnosed otherwise than by x-ray examination. If gas is present, surgical interference is at once indicated; if absent, one point at least has been established in favour of leaving well alone.

39. X-Ray Images in Stereoscopic Relief on the Screen.

To see the image on the fluorescent screen stereoscopically has long been the desire of radiologists, but the necessities of the war, when large numbers of wounded have to be examined and the position of a projectile or the site of a fracture localized as quickly as possible, have given the matter a fresh importance. GIBON (*Compt. rend. Acad.*

des Sciences, No. 161, 1915) gives particulars of three methods. In the first of these, two x-ray tubes are employed (or one tube with two anticathodes), and the diaphragm is placed between the tubes and the subject. This diaphragm consists of the leaves of a metal impermeable to x rays save for an opening of variable width. Starting from the first tube, the rays pass through the opening of the diaphragm and the body of the patient, forming an image on the platinocyanide screen. The rays from the second tube form another image, and these two projections, slightly dissimilar, make a stereoscopic pair, which can be viewed with a Wheatstone stereoscope. The relief is proportional to the distance apart of the tubes, and the distance from the diaphragm to the screen. The maximum width of the diaphragm window must always be less than the separation of the two anticathodes. A second method involves the use of a special screen consisting of a plated or corrugated metallic sheet, again with two tubes in action. The rays from the tube to the left, after passing through the part to be examined, rendered fluorescent only the plaits or corrugations to the right, for they traverse perpendicularly only the minimum thickness of metal, whereas the rays from the same tube, before reaching the plaits to the left, have to meet obliquely a greater thickness of metal, and in consequence do not irradiate the platinocyanide. The same thing happens in the reverse sense in the case of the rays from the other tube, and thus a stereoscopic pair is formed of alternate bands of the separate images, which it is sufficient to observe in a mirror stereoscope. The mirrors reflect, one of them the plaits to the right and the other the plaits to the left, so that each image appears to be continuous, and on both being examined simultaneously they give the effect of relief. A small screen, sufficient for the examination of the limbs, may be constructed by taking a sheet of aluminium, 1 mm. in thickness, 50 cm. in length, allowing about 20 cm. for the plaiting or corrugation, the plaits being about 8 mm. in breadth. If the distance from the screen to the tube be 50 cm., and the separation of the anticathodes be 20 cm., the angle of the plaits of the screen should be about 30 degrees. A third method consists again of employing two tubes, but with double obturators, or shutters, so that each eye perceives only the projection of the tube to which it corresponds. By alternately masking each tube at a rapidity of about five times per second, and allowing each eye to see only its separate image, one may obtain the impression of an image in continuous relief, thanks to the persistence of the retinal image, and also to some persistence of the fluorescence of the platinocyanide screen. A useful obturator may be obtained by a number of methods, but the most efficient would be one by which the action of the obturators is controlled by the actual passing of the current alternately through each of the tubes.

40. Extension Apparatus for Fracture of the Humerus.

J. ABADIE (*Bull. et mêm. de la Soc. de Chir. de Paris*, July 6th, 1915) describes an extension apparatus for fractures of the humerus which gives results similar to those obtained by means of Delbet's apparatus, and has as an additional advantage that it can be quickly made out of materials which are possessed by every ambulance. The apparatus is made up of several parts. A wire-work or perforated splint or a piece of zinc of about 20 cm. by 6 cm. (7.8 in. by 2.3 in.) is bent into three parts at right angles to one another, one of the turned-up ends being twice as long as the other. Next a piece of hoop iron 50 cm. in length (19.5 in.) is taken, and at the end intended for the lower end of the splint a length of 6 cm. (2.3 in.) is bent at right angles to the stem, while at the other and upper end the iron is bent on itself twice so as to form a hook. The lower end of the iron is now inserted into the three-sided splint, so that the longer end of the small splint lies outside and parallel to the iron stem, and the shorter end of the small splint is doubled over the foot of the iron one. The two are fastened together by means of plaster-of-Paris bandage. Next are made two arches of iron wire; the lower one, which is well padded, is in the shape of a double crescent, and is intended to pass below the axilla; the upper arch, which can be hooked into the lower one, to pass above the shoulder. The points of application of the extending forces are the upper part of the forearm with the elbow bent at right angles and the axilla respectively. In applying the apparatus, the upper end of the forearm and lower end of the arm are well padded and the lower angle of the splint fitted well into the bend of the elbow, the splint being maintained in position by turns of bandage; the iron-wire arches are applied under the axilla and above the shoulder and hooked together. Continuous

elastic force for extension is then obtained by several turns of india-rubber tubing, which pass over the hook on the upper end of the iron stem and below the upper iron-wire arch; the amount of traction is easily regulated by the thickness of the india-rubber employed, the number of turns taken, and the amount of tension given initially to the india-rubber. Certain precautions need to be observed in applying the apparatus. The front of the shoulder should be well padded, or, better still, the iron stem bent so as to avoid undue pressure in this region. The direction of the hook at the upper end of the iron stem may need to be slightly incurved, in order that the direction of traction may be parallel to the long axis of the humerus. The time needed for the construction and application of the apparatus is from fifteen to twenty minutes, but if the necessary apparatus is made beforehand, as can easily be done, not more than five minutes is needed to put it in position. Compound fractures can easily be dressed without disturbing the splint, space is left between the iron stem and the arm and the part of the arm which is accessible comprises from 5 cm. (1.9 in.) above the bend of the elbow to the axilla and the acromion process. The results obtained are the same as those obtained from the use of Delbet's apparatus. Preliminary reduction of the fracture is unnecessary since coaptation takes place progressively. Pain ceases almost immediately. A special advantage of the method is the freedom of movement allowed to the arm without cessation of traction.

41. Wounds of Abdomen.

At a meeting of the Société de Chirurgie on December 1st, 1915, MARQUIS, of Rennes, presented statistics of 68 cases of abdominal wounds from the battle of the Marne which were almost of necessity treated by expectancy on account of conditions which made suitable intervention impossible (*Paris méd.*, January 1st, 1916). Of the whole number, 36 died and 32 recovered. A certain number of the wounds were not penetrating, and in 21 in which there was penetration the projectile was a bullet. He concluded that when a large number of wounded had to be dealt with, abstention from operation and placing the man in Fowler's position with injection of serum, and in certain cases rectal irrigation, gave satisfactory results. Speaking of 84 cases of penetrating wounds of the abdomen communicated by STERN, ROCHARD reviewed all the cases of intervention and abstention in such injuries which had been presented to the society since the beginning of the war. From his clinical records he concluded that laparotomy was the only treatment applicable to war wounds, as it was to those of civil life.

42. Wounds of the Spleen.

At a meeting of the Société de Chirurgie on October 27th, 1915 (*Paris méd.*, November 27th, 1915), WILLEMS of Ghent read a communication on wounds of the spleen. He had performed five splenectomies for rupture of the organ only a few hours after the infliction of the wound. All the patients died, doubtless, he thought, on account of the circulatory disturbances caused by the suppression of a healthy gland in full work and not compensated for. QUÉNU said he had also observed the gravity of wounds of the spleen caused by projectiles. ROUTIER thought the gravity of splenectomy was not due solely to the removal of an important organ. There must be an unknown factor, for he had operated in at least three cases for wound or rupture of the spleen, and all his patients got well. HARTMANN also mentioned several cases of successful removal of a healthy spleen. WILLEMS pointed out that the cases he had seen were instances of true bursting of the organ, not simple perforations.

43. War Deafness.

At a sitting of the Académie de Médecine on December 21st, 1915 (*Paris méd.*, January 1st, 1916), LANNOIS and CHAVANNE read a paper based on the observation of a thousand cases of war deafness treated at the oto-rhino-laryngological centre of the Fourteenth Region. The prognosis depended on two factors: (1) The previous condition of the auditory apparatus. Men suffering from chronic suppurative otitis media, or well-marked sclerosis, after commotion of the labyrinth by the bursting of shells, showed an incomparably greater proportion of deafness or impaired hearing than healthy subjects. Of 189 men sent back from the front for chronic suppurative otitis media, intensified by concussion caused by shell, only 43 per cent. were returned to the fighting line; 56 per cent. were passed into the auxiliary services; 1 per cent. was discharged as unfit. Of 134 cases of sclerosis sent back on account of defective hearing after some

months of campaigning, 48 per cent. were passed into the auxiliary services, while 52 per cent. were returned to the fighting line. (2) The existence or otherwise of a direct injury to the skull, deafness being almost the rule in traumatic mastoiditis (about 95 per cent.); frequent in traumatism of the branches of facial nerves distributed to the ear (about 30 to 40 per cent.); rare in fractures of the cranial vault. In such cases it was generally unilateral deafness that was produced. If there was no direct traumatism, concussion of the labyrinth was rarely followed by deafness. In 645 cases with and without rupture of the drumhead, the authors saw only 2 per cent. of cases of definitive bilateral deafness. This proportion was 5 per cent. among 262 cases of pure concussion without rupture, the rupture being, in fact, a factor making for mitigation of the effects of the injury owing to the immediate decompression which it caused. Acoustic exercises had no effect on definitive deafness due to concussion of the labyrinth. Recourse must be had to lessons in lip reading if the victims of such injury were to be kept in touch with social life. Great care must be taken before giving a prognosis, to exclude malingering. The authors had found simulation in 11 per cent. of their 262 cases of pure labyrinthine concussion. Simple deafness and deafness with dumbness from traumatic neurosis got well the more quickly the patient received suitable treatment.

At a meeting of the Académie des Sciences on November 15th (*Paris méd.*, November 27th, 1915) DELAGE read, on behalf of MARAGE, a paper describing the treatment employed by him in the case of soldiers who had been made deaf and dumb without apparent lesion by the bursting of high explosives. If hearing and speech are not recovered within a few weeks, they may be permanently lost. Marage applies mechanical vibratory massage to the larynx and the sides of the neck, thus calling into play both the intrinsic and the extrinsic muscles of the larynx. The patients treated in this way began to speak after a few days, and in three weeks completely recovered their speech. They had been deaf and dumb for four or five months, and all other methods of treatment had failed.

44. Chronic Traumatic Oedema of the Back of the Hand.

DISCUSSING the hard traumatic oedema of the back of the hand, first described in 1902 by Vulliet, L. LEVY (*Deut. med. Woch.*, August 12th, 1915) records 3 cases among about 1,000 patients treated in the orthopaedic department of a military hospital. The first patient crushed his hand between two pieces of wood in a railway accident; the second patient was struck on the back of the hand with the butt of a rifle. The third patient was a man, aged 31, healthy and powerfully built. A blow on the back of the right hand, given by the blunt end of a hatchet, provoked severe pain, which was soon followed by great swelling of the hand. Though no effusion of blood could be detected, the skin became livid, and it was very difficult for the patient to close his fist. Wet compresses were applied. He remained on active service after the accident, although he could not hold his rifle properly. Six weeks later he was given sick leave, and the swelling was then still firmer, and the fingers were more rigid than before. The condition was but little affected by massage and warm hand baths, and four and a half months after the accident the swelling was as hard as a pumped-up rubber tyre. Whilst the swelling tapered away over the backs of the first four fingers, it ceased abruptly at the back of the wrist and at the bases of the fifth finger and the thumb. The palmar aspect of the hand was not swollen. The skin over the swelling was livid and tense; it could not be pinched into folds and showed no pitting on pressure. On passive movement the fingers, which were extended, could be made to turn about an angle of 15 degrees; but the patient could not move them voluntarily. The *x* rays revealed marked atrophy of the bones, but showed no sign of fracture. Orthopaedic exercises have been found of little value in the treatment of these cases, and the author therefore confined the treatment to daily hot air baths at a temperature of 70° C. Later, eighteen injections of fibrolysin were given, and the patient was discharged more than half a year after the accident without any improvement having been effected. The pathology of this condition, which the author thinks is probably a trophoneurosis, is not fully understood, and no effective microscopic study of the tissues concerned has yet been made. But the author is certain that the atrophy of the bones, as shown by the *x* rays, is merely a secondary phenomenon, due to the

interference of the oedema with the nutrition of the bones. This atrophy is not characteristic of chronic idiopathic oedema; and it is also observed in cases of fracture of the metacarpal bones associated with oedema.

45. Localization of Foreign Bodies by Electro-vibration.

PHOCAS (*Arch. d'électr. méd.*, November, 1915) has described to the Société de Chirurgie a case in which a number of small fragmented foreign bodies were extracted under the guidance of the Bergonié electro-vibreur (an electro-magnet charged with alternating current, which sets up induced currents, and consequent vibration, in metal fragments within its field of influence). The case in question was that of a soldier who had received a splinter of shell on the external face of the thigh. The splinter encountered a knife which was in the man's pocket, and this it broke into several pieces, which were sent into the flesh, and it was itself broken into particles. Five of the fragments were extracted under local anaesthesia (cocaine), the electro-vibreur successfully making the localization, and confirming the *x*-ray localization which had previously been made. The largest of the splinters was of the size of a small nut. A month later a further operation took place, also under local anaesthesia, and six small splinters were extracted, some of which appeared to have formed the handle of the knife, and others the blade. Yet another operation, under chloroform, took place a fortnight later, and the remaining piece of metal was extracted. Cicatrization was obtained within two months of the first examination, which itself took place more than two months after the date of the wound. The author considers the method a valuable one in shell wounds where there has been much fragmentation.

THERAPEUTICS.

46. Treatment of Dysentery.

AT a meeting of the Réunion des Médecins de la IV^e Armée on December 3rd, 1915 (*Paris méd.*, January 1st, 1916), P. EMILE WEIL said he had, by the use of emetine hydrochloride in doses of 8 to 20 centigrams in the day administered by hypodermic injection, got far better results in dysentery and dysenteriform diarrhoea than those obtained with collargol, bismuth, or sodium salicylate. After the first injection the stools diminished in number by at least one-half. He found that the drug acted as well in ordinary dysentery as in the amoebic form. LEON GIROUX said that he had treated 172 cases of diarrhoea, two-thirds of which showed the characters of dysentery. He insisted on the value of the urinary crisis with free discharge of chlorides associated with bradycardia as signs of convalescence. He had only four deaths. The complications noticed were a febrile choluric jaundice; paratyphoid infection in three cases, in one of which the *B. dysenteriae* was found in the stools; joint and muscle pains in some cases accompanied by scarlatiniform erythema, herpes in two cases, paroxysmal tachycardia in two cases; four cases of transient albuminuria, one case of diaphragmatic pleurisy, and one of Raynaud's syndrome. He used antidysenteric serum in cases where the corresponding infection might be suspected. When this first treatment remained without effect, and in general in all cases of bloody diarrhoea, he used emetine in doses of 0.04 gram daily with excellent results. In choleric diarrhoea he recommended, besides cardio-tonic medication, morphinized serum for the muscular cramps. FÉLIX RAMOND, in dealing with glairy bloody frothy stools with very putrid smell but without *B. dysenteriae* or amoebae, recommended a carbohydrate diet and bactericidal medication of the colon by means of enemas of lactosed water, 50 per 1,000, to which laudanum might be added. These should be retained as long as possible, as they acted by the lactic acid which they produced in the intestine. From six to eight hours after the lactose enema a litre to a litre and a half of oxygen could be injected. After two or three days of carbohydrate diet it was advisable to give raw or underdone meat and milk. Whilst the diarrhoea lasted acids and bile given by the mouth were of some value. Opiates were indicated in painful forms.

At a meeting of the Société Médicale des Hôpitaux on October 22nd, 1915 (*Paris méd.*, November 27th, 1915) MILIAN reported that for two or three years he had used arseno-benzol with success in the treatment of amoebic dysentery.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

War Number.

MEDICINE.

47. Cerebro-spinal Meningitis.

JEAN PIGNOT, médecin aide-major de réserve, and JEAN TERRASSE, médecin auxiliaire (*Paris méd.*, November 27th, 1915) were entrusted with the establishment of a station for the treatment of cerebro-spinal meningitis some kilometres from the French front. During a period of four months twenty-six patients were admitted to the huts; of these twenty-two were completely cured. The authors attribute this successful result to the fact that the majority of the cases were discovered at the very beginning of the disease, and that a special service working night and day prevented any delay in administering the first injection of serum. The patients, almost all of whom were found either in the trenches or the cantonments, were for the most part sent to them within the first twenty-four hours by special automobile, and the first lumbar puncture was performed immediately on their arrival. Speaking generally, even when the symptoms of meningeal reaction were but slightly marked, the presence of a cerebro-spinal liquid even slightly opalescent was judged to be a sufficient indication for an immediate massive injection of serum. The clinical diagnosis was always verified within a few minutes of puncture by microscopic examination. After the injection the patient was immediately placed with his head lower than his feet; after lying in this position for three-quarters of an hour he was put to bed in the normal position. The morphology and abundance of the meningococci were taken as guides in fixing the second dose injected the next day. The injections were given in decreasing doses till the liquid returned was almost normal and the pathogenic agent had almost completely disappeared. The quantity of serum injected varied from 200 to 300 c.cm. As there was little facility for bathing, tepid affusions were used instead. To all the patients was administered urotropine in solution, in a dose of 1 gram a day during the febrile period; those among them in whom the flow of urine was insufficient received on several consecutive days a hypodermic injection of 250 grams of artificial serum, to which 10 to 15 cg. of spartein sulphate were added. Vegetable soup and milk, condensed or otherwise, was the only food allowed in the acute stage. On the fifteenth day they were allowed to get up. After a few weeks, during which the rhino-pharynx was disinfected with gomenol [said to be a distilled essence of *Melaleuca viridiflora*, a plant indigenous to New Caledonia] and menthol oil, they were sent back to the interior to complete their convalescence. The authors point out that although the clinical forms of cerebro-spinal meningitis are extremely varied, those in the adult which came under their hands almost all presented the same evolution. The symptoms of onset were for the most part violent headache, nausea, pains in the limbs, and high fever. The onset was so sudden that most patients were able to tell the exact hour at which they began to feel ill. The most trustworthy symptom was stiffness or simply painful discomfort in the nape of the neck; this was so constant that it was often taken as an indication for lumbar puncture. Of all the pains complained of, headache, chiefly in the frontal and occipital regions, was the most violent. Vomiting was rarer, although nausea occasionally persisted for some time. Constipation, though not obstinate, was more frequent than diarrhoea. In no case was the photophobia so often met with in other forms of meningitis, especially the tuberculous, observed; the authors were struck by the clear brilliant look of the eyes. There was generally no loss of consciousness, and even those who had become comatose recovered their intellectual faculties with fair rapidity after the serum treatment. Hyperaesthesia and hyperalgesia of the skin were unfailing symptoms. Sometimes true tonic convulsive crises, with opisthotonos like to that seen in patients with tetanus, were observed. This made the injections very difficult. The pulse, which was taken very regularly, showed great instability, but was generally well marked

and not slow. Albumin was never found in the urine. Several patients presented a well-marked herpetic eruption on the face, lips, chin, and the lobes of the ear, never on the rest of the body or the mucous membrane. Sero-toxic rashes, however, were seen in some patients from the eighth to the twelfth day after the first injection. The authors never observed any sign of anaphylaxis when injections were begun again in cases of relapse. They conclude by emphasizing the importance of recognizing a meningeal reaction at the earliest possible moment. When a cerebro-spinal fluid of suspicious aspect is found an injection of antimeningococcus serum should be given forthwith.

48. Typhoid and Paratyphoid Mortality.

AT a meeting of the Réunion Médico-Chirurgicale de la IV Armée held on January 14th, 1916 (*Paris méd.*, February 19th, 1916), BORDIN read a communication in which he stated that, according to his own observations, the mortality of typhoid conditions had diminished to a considerable extent since the autumn of 1914, when it was 18 per cent., till the summer and autumn of 1915, when it was only 1.6 per cent. This diminution, he said, was due to the progressive and almost absolute disappearance of Eberthian enteric, which now accounts for only 5 to 6 per cent. of all typhoid conditions. The result is due to anti-typhoid vaccination, the fever only exceptionally attacking those protected by that method. On the other hand, paratyphoid attacks those vaccinated against typhoid in the proportion of 87 per cent. The paratyphoid mortality is very low in the hospital in which he works. Whilst the typhoid mortality varies from 14 to 17 per cent., that of paratyphoid B is 6 per cent., and that of paratyphoid A only 1.4 per cent.

49. Submarine Casualties.

AT the annual meeting of the American Association of Military Surgeons, held at Washington in September, 1915 (*Military Surgeon*, January, 1916), W. H. HALSEY, Past Assistant Surgeon U.S. Navy, read a paper on submarine casualties. He says diphtheria, the exanthemata, cerebro-spinal meningitis, tuberculosis, and all communicable diseases, including gonorrhoea and syphilis, are a menace to the efficiency of the submarine, and injuries, however slight, may hold most serious potentialities. An illness or injury occurring on a battleship, which would hardly keep a man from performing ordinary duty, if occurring on a submarine would necessitate the immediate removal of the man to the sick bay of the tender or to a hospital. As the number of men is limited this could not happen many times without serious consequences. The problem before the medical officer, therefore, is mainly that of prevention. Halsey classifies the incidence of conditions which may endanger the health or life of the crew as follows: (a) *When the submarine is on the surface, either stationary or under way:* (1) Gasoline poisoning (in the gasoline type of boat) due to unburned gas coming from breaks in the supply line. (2) Gasoline poisoning due to back fires in the exhaust, which fill the boat with partially burned gas. (3) Gasoline explosions. (4) Trauma due to falls from deck through hatches. (5) Drowning; men may fall or be swept overboard. (b) *Submarine on surface and under way:* (1) Sea-sickness. (2) Drowning; men may be washed overboard either from deck or from temporary bridge, from which place the submarine is frequently navigated while cruising. (3) Ramming or being rammed by another submarine or destroyer, or striking an obstruction to navigation. (4) Trauma due to violent shifting of the boat or to being struck by heavy objects adrift inside the boat. (c) *Submarine awash or submerged:* (1) Leaks in watertight body of boat. (2) Leaks into battery tanks and generation of HCl gas. (3) Battery explosions (explosive combination of free battery hydrogen and the oxygen of the air). (4) Ramming or being rammed. (5) Vitiating of air. (6) Noxious gases from ballast tanks after long disuse, notably marsh gas. (7) Inability to regain positive buoyancy owing to submergence at too great a depth. (8) Inability to right the boat and bring her

to an even keel at the proper depth; boat has down rudder and engines are giving the downward impetus. (9) Leakage of compressed air, so that not enough is left to blow the tanks or to revitalize the air in the boat. (10) Explosion of torpedo in tube. (11) Torpedo stuck in tube and its engines running. Friction generated intense heat. (12) Terrific cold in northern waters in winter. (13) Explosives dropped from aeroplanes. Among the phobias and psychasthenias exhibited in members of submarine crews, Halsey says the fear of submerging is rare, but the dread of submerging to too great a depth is often present. This latter fear may affect one individual or the whole crew, so that every man in range is covertly watching the depth gauge as soon as it begins to register. The fear of striking the keel of a passing ship in rising has been noted several times. Psychasthenia and neurasthenia must be constantly watched for, for an excitable individual in a submerged boat may destroy the moral of the crew in a moment. Dealing with the casualties more in detail, Halsey says the ever-impending danger to the crew both in peace and war is death by suffocation. The asphyxiating gas may be CO_2 , HCl , Cl , gasoline or the fumes from the oil which has burnt in the oil-burning type of boat. If the mechanism which allows the replacement of water by air in the submarine ballast tanks fails to work when a boat is submerged beyond a certain depth, the men in the submarine must make the most of the few hours of life left to them. Death from carbon dioxide poisoning is inevitable. Another possibility of asphyxiation by vitiated air lies in too long submergence when eluding an enemy or manoeuvring in position to attack. Then there is a certain depth beyond which a boat cannot go and again regain the surface. This point is determined by two factors: the amount of pressure which the sides of the boat will stand without collapsing, and the air pressure available to overcome the water pressure in the ballast tank. When the depth is too great there is an increased pressure, the plate seams begin to give, the submarine continues to go down, and suddenly collapses like an eggshell. The generation of chlorine or hydrochloric acid gas and its diffusion throughout the boat may occur through salt water leaking into the battery tank. The acid electro light reacts with NaCl to produce free hydrochloric acid gas and free chlorine. The effect of breathing these gases in such small dilution as the air in a submarine can afford is readily imagined. The vapours of gasoline, burnt or unburnt, are much less deadly—first, because the gasoline engines are used only on the surface, and secondly, because these gases are much less irritating to the lungs and mucous membrane. The insidious onset of gasoline intoxication, however, and its violent nerve manifestations make it a formidable possibility. The nervous phenomena run the gamut from wild delirium to profound coma. The crew become more or less used to the continuous odour of gasoline, and thus are not conscious of the impregnation of the atmosphere with the fumes until one of them drops to the deck unconscious or raves about in delirium. All the men in a compartment may be affected in quick succession, and speedy ventilation of the boat becomes imperative. The crew of a submarine is subject to the benumbing effects of cold in winter and to the oppressive effects of heat in summer. The heat is especially felt in tropical waters. The men are almost always in a state of high nervous tension, and it can never be said that they are comfortable as comfort is ordinarily known. Dangers from within and without threaten them continually, yet, says Halsey, a more cheery, uncomplaining, courageous set of officers and men would be hard to find.

50. War Psychoses.

A. B. GERVER (*Russkii Vrach*, xiv, No. 36, abstracted in the *Military Surgeon*, the organ of the military surgeons of the United States, January, 1916) divides war psychoses into three classes: (1) Those arising in men without hereditary taint and due solely to the war environment and to violent emotions caused by battles; (2) psychoses which would develop in ordinary peace circumstances, but the onset of which is precipitated by the war; (3) dementia praecox, manic-depressive insanity, paranoia, paralytic dementia; to this class belong traumatic psychoses caused by wounds and contusions. The psychoses of the first category do not differ in any way from the old type, but may be subdivided into those caused by battles, by trench life, and rearguard psychosis. Clinically they belong to the acute mental disorders, amnesia and asthenic psychoses. They often develop in the form of neurasthenic insanities. The specific character of all three classes consists in the peculiar

colouring and nature of the hallucinations, illusions, delusions, and conduct. The hallucinations and delusions take their special character from the experiences of war life; another feature is depression, often followed by excitement and confusion of consciousness. The nature of the fighting (artillery, infantry, bayonet attacks, etc.), the duration of the war, life at the front, the course of military events (offensive or defensive), victory or defeat, and the general moral of the army determine the larger or smaller proportion of the psychoses. Gerver holds that in the present war the proportion of psychoses is relatively small, being only about 1 per 1,000, whereas in previous wars it was 2 or 3 per 1,000. The main cause of the decreased rate is the absence of alcoholism, which in the Russo-Japanese war was responsible for one-third of all the psychoses. In the present campaign not a single case of alcoholic insanity has been observed in the Russian army.

SURGERY.

51. Wounds by Small Projectiles.

H. ROULLAND (*Paris méd.*, January 29th, 1916) states that three things characterize wounds by small projectiles—the insignificant appearance of the lesions; the depth of penetration of the projectile, and the rapidity and gravity of the infectious phenomena. This special septicity seems to be due to the smallness of the aperture of entry and the passage through the tissues—the muscular fibres come together behind the projectile, forming a closed chamber, a circumstance eminently favourable to the growth of germs carried in by fragments of cloth, hairs, etc. The man comes to the ambulance as a *petit blessé* with a very small wound, sometimes already covered by a dark-red crust; the aperture of entry varies in size from a pea to a franc piece, and one would often be tempted to believe that this represents the whole extent of the injury. But in the great majority of cases the projectile has penetrated. If the crust is removed a reddish muddy liquid, sometimes mixed with gas, flows out; a hollow probe introduced into the small hole goes to the projectile if that has remained embedded under the skin, or lies buried in a part where the muscles are not very thick (hand, foot, head). It stops at the aponeurosis if it is among thick muscles or in a tendinous region (thigh, leg, arm, buttock, back), and the surgeon may think that the projectile has not penetrated deeper. If the probe goes through the aponeurosis, an artificial intramuscular passage sometimes far removed from that of the projectile will easily be made. That often strikes obliquely from below upwards, and makes tortuous passages sometimes of ten or twelve centimetres in depth. All shell wounds are greatly contused owing to the irregularity of the projectiles, to the force of propulsion, perhaps also to high temperature causing a true burn. Even when the wound involves only the skin and cellular tissue, it produces a special mortification of the tissues which take on a greyish aspect with red border in which repair takes place with difficulty. These wounds are always infected. When the projectile has penetrated into a muscular mass it causes either a localized infection in the form of a small abscess which is easily emptied, or a more extensive infection with microbic agents of special virulence which cause a true gas phlegmon. These infections develop with astonishing rapidity, stripping the muscles along the aponeurosis; Roulland has seen this occur within six, eight, or ten hours of the infliction of the injury. Infection may spread over a whole region or limb and end in septicæmia of great gravity. When a projectile of at least 1 cm. square strikes a short bone (carpus, finger, tarsus) it pulverizes it or splits it lengthwise; in a long bone it embeds itself on the external surface. Every bone lesion gives rise to great pain which is sometimes worst when the wound is smallest. It is extremely intense at the point of fracture or embedding, and is often accompanied by local oedema or ecchymosis. Lesions of the bones of the skull have special characters, according as the projectile remains embedded under the skin, buries itself in the bone or passes entirely through it. If it only strikes the bone it sometimes produces a small star-shaped crack of the outer table. This slight injury is to be distinguished from tangential wounds which almost always cause injury of the brain and hæmorrhage. When the projectile buries itself in the outer table it causes fracture of the inner table, which is driven in over a considerably larger surface than the orifice made by the projectile. In every case in which Roulland has seen the

small metal fragments embedded in the thickness of the bone he has found damage of the inner table. When the projectile traverses the bones of the skull it produces meningeal or cerebral lesions, which are always serious and quickly become infected (abscess of the dura or the brain). Even very small projectiles may cause such lesions; therefore all wounds of the head should be examined with the greatest care. As an example, Roulland cites the case of a soldier sent to the ambulance with the diagnosis of superficial abscess of the scalp. It was found that he had been wounded twenty-five days before by a very small fragment of shell which penetrated at the level of the upper part of the squamous portion of the left temporal. The medical officer of his battalion, believing the wound to be of no importance, kept him seven days under observation, and, the skin wound being then healed, sent him back to the trench. The man continued to suffer from slight general discomfort, till suddenly, eleven days after the infliction of the wound, total aphasia came on, with nausea, vomiting, and violent headache. He was kept at rest, and the aphasia disappeared in two days, but the general phenomena persisted. A few days later there was violent pain in the cicatrized wound, and a subcutaneous abscess formed. He was then sent to the ambulance, where Roulland freely incised the abscess and discovered a small hole, which allowed the introduction of the end of a hollow probe, and led to a subdural abscess. Trephining showed that there was a shirt-stud abscess, caused by a penetrating projectile which had not been recognized. The operation was followed by the relief of all the symptoms, and the man at the time of report was convalescent. In joints, especially the knee and shoulder, and in the abdomen, the smallest projectile causes serious injuries. When one lodges within the sheath of a blood vessel, lesions of the coats are produced, which cause secondary haemorrhage and the formation of aneurysms. Roulland has found in several cases the projectile lying in the very centre of the aneurysmal sac; speedy extraction generally prevents serious consequences. In the case of an infected wound a free incision should be made, the foreign body should be sought for generally in the centre of the focus of infection, free drainage should be provided, and the wound should be irrigated with oxygenated water. In bone lesions the seat of fracture should be exposed, especially in wounds of the hands or feet, which are often complicated by tendinous lesions. Adherent splinters if they are of any size should be left, but the foreign body should always be removed. After careful cleansing free drainage should be provided. Wounds of the skull should be operated on at the earliest moment, and it is essential as far as possible to avoid sacrifice of bony substance. If the dura is injured careful cleansing and drainage are required; if it is intact it should be incised only if there is no longer any visible pulsation. Roulland thinks that the crucial incision should be avoided, as it gives rise to great loss of substance and is repaired with difficulty. Simple puncture with the bistoury has always given him the best results. He drains with a strip of gauze steeped in alcohol. In wounds of joints early operation is required; the foreign body should be found, the sac cleansed, bony splinters removed, and free drainage provided. Every articular intervention should be done under the most rigorous antiseptics. Roulland says that in war surgery hot water applied to the injured part in the form of local baths, wet dressings, or sprays, has given him excellent results; it has a very salutary trophic action on the mortified tissues. He uses it together with lavages and dressings of oxygenated water. The moist dressing should be discontinued as soon as the inflammatory phenomena have disappeared. The neighbouring skin should be carefully washed with alcohol at every dressing. Antisepsis must be used in dealing with these infected wounds, but it must always be remembered that contused tissues have a lowered vitality and nothing must be done to injure the living cell. On this account Roulland very seldom uses tincture of iodine, which he has known in many cases to cause burns, sometimes of considerable extent, without advantage to the patient. For some time he has used the Carrel-Dakin method of disinfection. He finds sodium hypochlorite 0.5 per cent. decidedly better than the old wet dressing, but its use must not be too prolonged, as it seems to encourage oozing of the blood-stained surfaces and to prevent epidermization. In extensive wounds, which are only slightly infected, or which are cicatrizing, the application of compresses soaked in warm physiological serum gives excellent results. He prefers the Locke-Ringer formula: Sodium chloride 9 grams, potassium chloride 0.42 gram, calcium chloride 0.24 gram, sodium bicarbonate 0.15 gram, distilled water

1,000 grams; sterilize. Use as a dressing this solution increases the phagocytic properties of the white corpuscles, and clinically one sees rapid disappearance of suppuration and more rapid granulation and cicatrization than under any other dressing. Locke's serum has also shown itself superior to the ordinary physiological solution in subcutaneous or intravenous injections. Roulland has also used helio-therapy with advantage. He exposes wounds that are only slowly cicatrizing directly to the sun's rays for a period varying from one minute to twenty. The susceptibility of the integuments must always be taken into account and the time of exposure must be graduated according to the intensity of the sun's rays. Hot air judiciously used proved successful in anfractuons wounds which did not heal. Roulland thinks a projectile which has penetrated deeply without causing infection should always be extracted if it can be reached, unless it is absolutely insignificant in size. If it gives no trouble now it is likely at some future time to cause a fistula which will not close, or will encapsule itself in a shell of thickened tissue which may imprison nerve endings, causing neuralgia and painful points in muscles. It will also interfere with the function of certain muscles such as the masseter (trismus), the temporal, the gluteals, and biceps. The foreign body should never be sought for without the help of the x ray. He concludes by insisting on the importance of quickly curing men wounded by small projectiles as they can be sent back to the firing line. On speedy extraction depends speediness of definitive cure.

52. Gunshot Wounds of the Abdomen.

SURGEON-GENERAL PROFESSOR DR. KRASKE (*Muench. med. Woch.*, September 28th, 1915; abstract in the *American Journal of Surgery*, February, 1916), reports the results of 39 cases of bullet wounds of the abdomen met with in the course of six weeks. In general he urges the earliest possible intervention in every case; he has never seen a spontaneous cure. Of the cases in which he operated, 9 came under treatment within twelve hours of the injury; 2 died and 7 were discharged cured. Of 21 cases seen within twenty-four hours, 10 died and 11 were discharged cured. In a third series of 8 cases seen within thirty-six hours, 6 died and 2 were saved. The fourth series consisted of one case, which died. The injuries were for the most part multiple, and were situated as follows: In the small intestine eighteen times, in the stomach five times, in the caecum and ascending colon eleven times, in the transverse colon once, and in the descending and pelvic colon four times. In several cases the projectile passed through the liver into the lung, injured the bones of the pelvis, and in one instance even shattered the humerus. The openings into the gut or stomach varied from a pin point to one admitting the finger tip. In the large majority of the cases there was free air; fluid and alimentary contents were present in the peritoneal cavity. All wounds were stitched, care being taken to provide against stricture. In a number of instances portions of the gut had to be resected. In others the imperilled portion was everted and dealt with at a later stage. Whenever possible the abdomen was sewed tight, even in cases where the peritoneum was inflamed. Irrigation was practised in every case; Kraske lays much stress on the value of this measure. In a number of cases tube and gauze drainage to suspicious areas was provided. His results were 51.3 per cent. cures, which he holds to be not unfavourable considering all the circumstances in this class of emergency surgery.

53. Lupus in the Austrian Army.

DR. LUDWIG SPITZER, in charge of a new hospital erected near Vienna by the society "Lupushellstätte," has lately reviewed the conditions under which civilians and soldiers suffering from lupus have been placed by the war (*Wien. med. Woch.*, November 6th, 1915). His hospital was originally intended only for civilians suffering from lupus, but 160 beds were set apart for soldiers. More than one hundred of these were suffering from dysentery, but there was also a fair sprinkling of men suffering from lupus. More than forty soldiers were thus invalided, and the actual number of patients suffering from lupus who had been passed by the military doctors was considerably greater. Many patients who had been discharged from the hospital as cured had joined the army after war was declared, and in some cases had suffered no harm from the strenuous life. The open air life and abundance of exercise have been healthier than the life of a mechanic in an insanitary workshop. But the

majority of patients suffering from lupus are weakened by other tuberculous infections—for example, enlarged glands or phthisis—and are therefore incapable of the physical strain of military duties. The risk of infection from one soldier to another was of itself sufficient to warrant the exclusion of every subject of lupus from the army. In the slight cases the disease might have been overlooked during the medical examination, but this excuse did not hold good for the more advanced cases; and Dr. Spitzer did not see a single case in which the disease was so slight that radical operative treatment was indicated. The war had, however, been the cause of many patients receiving treatment who would otherwise have been left untouched. Crowds of civilian patients had attended the hospital who, in time of peace, would never have found their way to Vienna. The military authorities had helped neglected patients in the remotest parts of the country to reach Vienna, where skilled treatment was available. Dr. Spitzer saw in this shuffling of patients by the war a prospect of an appreciable reduction in the incidence of the disease.

51. War Deafness.

At a meeting of the Académie des Sciences on November 16th, 1915 (*Paris méd.*, November 27th, 1915), ANDRÉ CASTEX said he had observed 27 cases of deafness following the bursting of large shells at close quarters. In some no direct injury was caused to the auditory centres or apparatus; in others, especially after violent shocks, rupture of the tympanum or labyrinth was seen. Between such patients and malingerers there is a vast category of deaf, dumb, and deaf-and-dumb. These were curable by re-education and persuasion when their functional trouble was of recent origin.

THERAPEUTICS.

55. Ethyl Chloride as an Anaesthetic in War Surgery.

JACQUES CARLES, physician, and A. CHARRIER, surgeon, to the Bordeaux hospitals, report (*Journ. de méd. de Bordeaux*, January, 1916) that they have used ethyl chloride for a year as a general anaesthetic in major surgery in the military hospital to which they are attached. They have employed it in 1,200 cases of laminectomy, amputation, resection, probing for projectiles, etc. In some cases the anaesthetic has been given for three-quarters of an hour and an hour without the slightest ill effect. Its advantages have been so conspicuous that its use has become general among their colleagues of the 4th Army. To realize the superiority of ethyl chloride as an anaesthetic in operations for serious wounds it must be remembered that in all cases the men were suffering from traumatic shock so severe as to threaten life during the two or three hours following admission. It often happened that the shock was prolonged during twenty-four or forty-eight hours, leaving the patients cold, collapsed, almost pulseless, and generally in such a condition that the slightest touch of a bistoury seemed likely to cause death. Evidently an anaesthetic having the least possible toxic effect was the only one that could be given. The quickness with which ethyl chloride is eliminated pointed to it as the most suitable agent. Sometimes the administration was followed by nausea and a little vomiting, but this was never violent and did not last long; as a rule, the patient was able to take food freely some hours—in some cases a few minutes—after the operation. Albuminuria was exceptional, and when it occurred it was slight and transient. There was no ill effect on the lungs, such as is caused by ether. Another advantage is that the administration of ethyl chloride can be entrusted to a person of little or no experience. The patient is put to sleep in a few seconds, and this saving of time may lead to a corresponding saving of life. The wounded man recovers full consciousness from a few seconds to two minutes after the discontinuance of the inhalation. This is of great importance when the hospital personnel is reduced to the lowest figure and may be inexperienced. The authors consider ethyl chloride safer than any other agent. In nearly 500 cases there was only one death, and that was in a patient with an enormous purulent effusion in the left side of the thorax, pushing the heart to the right, in whom the least movement in bed caused collapse. Usually no heart failure is to be feared. They admit that ethyl

chloride does not always produce such complete relaxation of the muscles as ether and chloroform; hence for delicate and prolonged abdominal operations these are preferable.

56. Treatment of Syphilis in War.

At a meeting of the Réunion Médico-Chirurgicale de la IV^e Armée, held on January 14th, 1916 (*Paris méd.*, February 19th, 1916), GOUBEAU read a communication on the treatment of syphilis in war. In primary syphilis he uses simultaneously arsenobenzol (giving four intravenous injections of 0.30, 0.40, 0.50, and 0.60 gram respectively) and mercury (0.30 to 0.40 gram in intramuscular injections, plus one injection of grey oil), then potassium iodide 3 grams a day during forty days. In secondary and tertiary cases he gives at first arsenic and mercury simultaneously, then potassium iodide during six weeks. Patients in the secondary and tertiary stages remain in his ambulance on the average twenty-two to twenty-five days; those in the primary stage thirty days. LACAPÈRE said he found arsenobenzol alone sufficient to effect a rapid cure in a large number of cases. He thought there was no advantage, and some disadvantage, in the systematic association of mercury and iodide with it; these remedies should be used in response to special indications. LENGLET also criticized the method of triple combined treatment, which he said imposed on the emunctories a work of excessive elimination, and had no definite advantage.

57. Magnesia Hypochlorite as an Antiseptic.

CHARLES MAYER (*Paris méd.*, February 19th, 1916) says that he has been led to seek for a substitute for sodium hypochlorite, which has certain disadvantages, owing to its caustic properties. He has found that magnesia hypochlorite gives satisfactory results. He has used solutions made by causing 190 grams of magnesia sulphate, first dissolved in 2 litres of water, to act on 100 grams of calcium chloride, also dissolved in 2 litres of water, then filtering the precipitate of sulphate of lime thus formed. To get a clear solution care must be taken to let the liquid stand until the precipitate is entirely deposited; then decant. Magnesia hypochlorite has an antiseptic potency slightly less than Labarraque's solution (chlorinated soda). To make various cultures used for experiment inactive 7 to 9 per cent. more was required. But as it is perfectly tolerated by the tissues twice as large a dose can be used without causing irritation of the wound. Generally speaking, with magnesia hypochlorite cicatrization proceeds as rapidly as with other antiseptics under the best conditions or even by operating aseptically. The tolerance of the tissues with regard to magnesia hypochlorite is not surprising, for whereas with sodium or calcium hypochlorite it is necessary to avoid all excess of alkalinity—for instance by the addition of boric acid—with magnesia hypochlorite not only is an excess of free magnesia not to be feared, but it should even be sought for. The advantages of magnesia hypochlorite are, briefly, its great antiseptic power, its non-causticity in useful doses, and its cheapness and facility of preparation.

58. Disinfection of the Meningococcal Carrier.

At a meeting of military surgeons in Cologne (*Deut. med. Woch.*, Sept. 9th, 1915) E. KÜSTER gave an account of his experiences of the treatment of diphtheria and meningococcus carriers. Early in 1915 a few cases of cerebrospinal fever were observed among the troops quartered in Cologne, and an investigation made at the bacteriological institute showed that 50 to 60 per cent. of the troops among whom these cases had occurred were carriers. As there was little prospect of sterilizing these carriers by individual treatment they were treated in an inhalatorium, 100 men at a time. The disinfectant used contained a hypochlorite which gives off chlorine on contact with acids or easily oxidized organic substances. Cultures of various micro-organisms, including meningococci, exposed to the action of this disinfectant were killed within an hour. After three visits to the inhalatorium on three successive days the carriers were no longer found to harbour meningococci in the nose and throat. Only in a few cases was a further course of inhalation necessary. The same results were obtained with diphtheria carriers. Although the inhalatorium smelt strongly of chlorine, which was without doubt present in the free state, no ill effects were observed.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

War Number.

MEDICINE.

59. Influence of War on Skin Affections.

BROcq (*Bull. méd. No. 3; Journ. de méd. et de chir. prat.*, March 10th, 1916), after a passing reference to the terrible increase in the prevalence of venereal diseases since the outbreak of hostilities, discusses the modifications which the war has produced in pruriginous dermatoses, psoriasis, and certain fistulous wounds. In almost all the civilians who before the war had suffered from pruriginous affections of neuropathic and autotoxic origin the symptoms returned or increased in intensity. When they have the opportunity of changing their abode for a time and avoiding crowded places, the skin lesions become milder or disappear. In large towns or in places where there is much bustle the symptoms return. Among the troops in the field, on the other hand, many who had previously suffered from urticaria, eczema, or pruriginous lesions, when forced to give up their usual occupations and live a life of strenuous exertion in the open air, found that the disease became milder or disappeared, without change of diet or local treatment. In some cases, however, a prolonged period of service at the front caused the outbreak of pruritus, urticaria, or papulo-vesicular eczema. These observations at first sight seem to be contradictory, but Brocq holds that in the majority of cases they are not so, because the patients have been submitted to altogether different conditions. The change in the mode of life, which in some men has had a favourable influence, has been prejudicial in others who have been exposed to excessive fatigue or violent emotions. Brocq calls special attention to the increased prevalence and severity of psoriasis among soldiers at the front, especially those in the trenches. He thinks the two chief causes of the "epidemic" are the almost exclusively flesh diet and nervous shock. Similar phenomena have been observed in peace time after great emotional disturbance or severe injury. Brocq also notes the occurrence of a number of cases of dermo-epidermitis in fistulous tracks in men who have been long under surgical treatment for bone injuries; in these cases a peculiar dermatosis developed around the wound.

SURGERY.

60. Lesions of the Larynx and Trachea in War.

GHERARDO FERRERI, Director of the Oto-Rhino-Laryngologic Clinic of the University of Rome (*Il Policlinico*, Sez. Pratica, January 23rd and February 6th, 1916), says that lesions of the larynx, trachea, and neighbouring parts are incomparably more frequent in modern warfare than in that of past times, owing to the increase in instruments of destruction, and to the use of asphyxiating gases and bombs containing poisonous vapours. Moreover, numerous inflammatory lesions are spread by contagion among the enormous masses of men in modern armies. Contributory causes are the prolonged stay in trenches, damp, want of ventilation, and defective light in the dug-outs, in which the virulence of all micro-organisms is increased. In addition to these factors must be reckoned the want of opportunity for regular change of clothing; thus the skin becomes covered with germs, which may easily have a mischievous action on a weakened body. Again, there are the dangers of transport in open railway carriages, automobiles, motor cycles, and bicycles, which expose the men to rapid changes of temperature and altitude, to irritation by dust and smoke—all circumstances likely to cause respiratory troubles in those who have any nasal obstruction. Hence, after a certain period of service soldiers are liable to haemoptysis and primary tuberculous lesions of the larynx from which in normal conditions they would not have suffered. Men in the secondary stage of syphilis suffer from rapid aggravation of throat lesions. In some predisposed to haematuria *a frigore*, or peliosis rheumatica, bleeding from the nose, trachea, and bronchi of an alarming extent often occurs. In albuminurics fatigue and cold are apt to bring on glomerulo-nephritis, a not infrequent symptom of which

is acute oedema of the glottis. Chondro-perichondritis, especially of the epiglottis, with partial necrosis caused by a common pyogenic agent, is not rare in soldiers attached to trains or doing automobile work. Injuries of the laryngo-tracheal tube hold a high place in the statistics of wounds of the upper part of the body. The so-called humanitarian bullet of modern warfare causes extensive lesions in the region of the neck, especially about the larynx and trachea, which cannot be immobilized like a fractured limb. Military life, especially on campaign, exposes soldiers suffering from faulty conformation of the naso-pharynx or predisposition of the adenoid tissue—palatine, lingual, pharyngeal, tonsillar, etc.—to inflammatory, hypertrophic and hyperplastic processes, which form a favourable soil for the development of pyogenic or infective germs, or for the lighting up of latent specific disease, such as tuberculosis and syphilis. In the examination of recruits care should be taken to weed out germ carriers, so as to avoid the development of grave epidemics—for instance, cerebro-spinal meningitis—among combatants. It used to be believed that adenoid growths were very rare in soldiers, but further observation has shown that they are fairly common, as in many men between 20 and 22 years of age the period of regression of the pharyngeal tonsil has not yet begun. In the treatment of inflammatory conditions caused by the irritation of cold air, asphyxiating gases, and smoke from guns Ferreri recommends inhalations, for which the ordinary mess tin can be used. This is filled with hot water, into which are poured some drops of a 5 per cent. alcoholic solution of balsam of Peru, 10 per cent. of tincture of benzoin, 5 per cent. of eucalyptus, 0.25 per cent. of menthol, 0.50 per cent. carbolic acid, 10 per cent. of laurel water, either separately or in combination. Sprays of solutions of sulphate of alum and potassium may be applied; or the following formula may be used: Sodium benzoate 2 grams, cocaine hypochlorate 20 cg., menthol 5 cg., pure alcohol 10 grams, distilled water 120 grams, laurel water 20 grams. Spraying should not be prolonged when the patient is fasting, as it is apt to cause cardiac disturbances and other reflex phenomena. Insufflations of powders into the larynx are useful because no complicated apparatus is required. Iodoform deodorized with essence of mint in the proportion of 5 drops per 1 gram may be used; tannin, aristol, or calomel may also be employed. For dysphagia and neuralgia medicated baths of the hypopharynx are preferable to ordinary gargles. The substances used may be official chloroform water or the following solution: Thymol 10 cg., basic cocaine 20 cg., menthol 20 cg., pure alcohol 100 grams, one coffeespoonful in a tumbler of tepid water; or salol 10 cg., basic cocaine 20 cg., menthol 10 cg., pure alcohol 100 grams, a coffeespoonful as before. Some of this is taken into the mouth and the head is bent backwards so that the occiput almost touches the upper part of the vertebral column; the liquid thus remains for some time in contact with the part. With a little practice this can be done without interference with the respiration. Soldiers should be told to avoid excess in alcohol, tobacco, hot or iced drinks, shouting and singing on the march; the exchange of glasses, tins, and other objects of personal use should be forbidden, and the mouth should be washed out from time to time with aniseed water. The affection to which soldiers are most subject is diffuse hyperaemia of the laryngeal mucosa, caused by breathing irritating vapours and powders, or by cold and rapid change of temperature. Men with chronic affections of the naso-pharynx and those exhausted by gastro-intestinal disturbance are most susceptible. Oedema of the larynx often occurs after fatigue or exposure to irritating inhalations or taking very hot food, and it may be so acute as to threaten life within a few hours. It has sometimes been observed as a premonitory symptom of acute infections—crystalpelas, typhoid, scarlatina. The prompt use of astringent sprays will generally give relief, but tracheotomy may be required. The author does not approve of intubation in such cases. In the way of general treatment bleeding, diuretics, and milk diet may be called for. Inflammation of the epiglottis, characterized by dysphagia, with pain shooting to the ear,

and a sense of a foreign body in the throat and some alteration in the voice, is a condition frequently observed in soldiers. The treatment is the same as for acute laryngitis. Abscess may follow either of these conditions, or may be the result of infection spreading from lesions of neighbouring parts. In mild cases the treatment is tepid antiseptic inhalations, revulsive applications to the neck and opening of the abscess, but if asphyxia seems to be impending tracheotomy will be required. Among other conditions that are apt to spread among troops are erysipelatos laryngitis and non-diphtheritic laryngitis with false membranes, in which the exudate is caused by the staphylococcus or pneumococcus. Treatment is the same as for acute inflammations of the throat; tracheotomy or intubation is seldom required and is best avoided, as these conditions are often followed by broncho-pulmonary disturbances. As regards diphtheria there is nothing special to soldiers. Tuberculosis of the larynx is frequent owing to fatigue and contagion. On the first suspicious sign the bacteriological diagnosis should be made, the patient should be speedily placed apart, and provisional local disinfection should be carried out by swabbing with a saturated solution of iodoform and ether after anaesthesia with cocaine. Perichondritis and chondro-perichondritis due to latent tuberculous processes are not uncommon. These may suddenly give rise to symptoms of asphyxia calling for tracheotomy. Specific syphilitic lesions are comparatively common, and are aggravated by cold, alcohol, smoke, etc. The spread of infection is facilitated by exchange of glasses and so forth. Under the influence of irritation by street dust, gas and smoke, the lesions of secondary syphilis are apt to ulcerate and become oedematous so as to simulate tuberculosis. Tertiary forms are less frequent. In secondary forms the object is to get rid of the contagious elements as quickly as possible; in tertiary to arrest the destructive process. The best way of doing this is by injections of neo-salvarsan and of calomel, 5 cg. in vaseline oil once a week, or of grey oil, three to four drops. If mercury is ill borne, biniodide or benzoate, 1 to 4 cg. per day, should be given. Locally the mouth should be disinfected with a solution of potassium chlorate. Tertiary cases, especially if tuberculosis accompanies the syphilis, should be sent to hospital.

61. Direct Laryngoscopy in War Wounds.

GUISEZ reported to the Académie de Médecine (*Bull. de l'Acad. de Méd.*, February 8th, 1916) that during eleven months of work as chief of the Oto-Laryngological Centre of the Tenth Region he had seen 32 cases of wound of the laryngo-tracheal tube—26 of the larynx and 6 of the trachea. In six cases there were well-defined oesophageal lesions, with foreign bodies lying immediately under the mucous lining. Direct laryngoscopy with the help of the tube spatula was of the greatest use in making possible diagnosis and effective intervention, as the larynx in all its parts was under the operator's hands. Under local anaesthesia the patient's head is placed in a position of forced extension, so that the axis of the larynx and that of the mouth are in the same straight line; the tube, the end of which pushes back the epiglottis and fixes it against the base of the tongue, is then introduced. The method is most useful in cases in which the sides of the pharynx fall inwards, and when the injury is situated at the anterior commissure. In two cases a portion of a vocal cord had been cut away, and in one of them the wound, which was altogether in the fore part, was hidden by a large epiglottitis. Aphonia and dyspnoea are sometimes caused by scars, which deform the cords or bind them together, principally at the re-entering angle. In five cases there was a true web; in one case the scar, which was part of a vocal cord, extended to the subglottic region of the opposite side, where it lost itself in a very thick cicatricial tissue. These conditions could only have been discovered by direct examination, and by that method alone was it possible to see the subglottic lesions and fibro-cicatricial bands at the level of the cricoid ring. In one case the cause of a persistent dysphagia was discovered to be a large polypus resulting from a fungating wound made by a shell in the right supra-arytenoid region. In another case serious dyspnoea was due to a fungating tumour connected with the right subglottic region and caused by a fragment of shell which had fractured the left half of the cricoid cartilage. In both cases it was possible to remove these inflammatory tumours with straight punch-forceps. Direct examination further allowed the recognition in a patient with dyspnoea of a large fistulous intralaryngeal abscess immediately below the left vocal cord, due to rupture of the thyroid cartilage by shell. The man was cured by laryngostomy. The same method showed that this procedure was indicated in two cases in which there

was serious stenosis of the glottic and crico-tracheal regions. Among lesions of the larynx paralysis was not rare. In four cases there was complete paralysis due to division of the trunk of the recurrent nerve and in two to division of the superior laryngeal nerve. The terminal expansions of these nerves were also injured in some cases. Direct examination with the help of the tube spatula offers the only means of recognizing such forms of paralysis and differentiating them from traumatic arytenoid ankylosis. The trachea may also be the seat of scars from perforating bullet wounds, sometimes with loss of substance due to shell injury, giving rise to very serious dyspnoea. Direct tracheoscopy enabled the author to make a precise diagnosis in three cases. In two of these there were started cicatrices of one of the walls and in the other a true cicatricial valvular ring. Tracheoscopy allowed dilatation by circular electrolysis and exact localization indicating where tracheotomy should be done when necessary, or showing whether it was possible to act directly on the lesion by enervative laryngo-tracheostomy. Direct examination of the oesophagus made it possible to recognize wounds of the gullet in five cases. In one patient on whom tracheotomy had to be performed for serious spasm of the glottis there was a phlegmon of the mouth and oesophagus, caused by a small fragment of shell embedded beneath its lining membrane. In three others there was grave cicatricial stenosis of the tube, in two in the upper, and in another in the lower third, caused by a bullet which had gone through the chest. In three others there was spasm of the oesophagus, in two at the upper, and in one at the lower end, all three due to irritation of the pneumogastric nerve, in the neighbourhood of which the projectile was lodged. In all these cases dilatation was carried out and treatment applied with the aid of the tube. In a few cases the endoscopic localization of foreign bodies was used to supplement the *x* rays. In one case a fragment of shell projected into the cavity of the gullet on the left wall a little below the upper end. In another it was lying between the oesophagus and the trachea at the level of the second ring, where it made a round projection on the posterior wall of the trachea. Intervention for the removal of foreign bodies was made easy by the use of the tube.

62. Transplantation of Cartilage in Plastic Surgery.

At a meeting of the Paris Surgical Society on October 27th, 1915 (*Bull. et mém. de la Soc. de Chir.*, November 2nd, 1915), H. MORESTIN read a paper on the use of cartilage for the repair of deformities caused by wounds. The method, he said, had for some time been employed in rhinoplasty, but had found a larger application in the surgery of the present war. Cartilage taken from any part would serve, but in practice the costal cartilages, particularly those of the sixth, seventh, and eighth ribs, were the most readily available. Resection of those cartilages was never followed by any ill effect if the intercostal musculo-aponeurotic layer was accurately reconstituted by means of deep and superficial sutures. The cartilage is easily trimmed with the bistoury to any shape that may be required. The transplanted fragments are grafted without difficulty, and adapt themselves with great rapidity to their new conditions of life. Not only is an immediately successful result the rule, but it is lasting. The grafted cartilage lives indefinitely without suffering absorption or appreciable diminution. Cartilage taken from another subject forms grafts as solid as those from the patient himself. But in this case Morestin is not quite sure that after a time they may not undergo some reduction. He grouped his cases in three categories: the filling in of breaches in the skull, of frontal depressions, and reconstitution of the upper orbital arch; reconstitution of the malar bone and the lower and outer parts of the orbit; and the repair of loss of substance in the lower maxillary bone. Morestin gave details of 23 cases in which the method was used, in most with gratifying success. In a later communication (*ibid.*, February 15th, 1916) Morestin reported that he had repaired breaches in the skull with grafts of cartilage in a large number of cases. Some instances may be given by way of illustration. (1) An officer was wounded on October 1st, 1915, by a fragment of shell which struck the upper part of the frontal and the neighbouring part of the parietal bone on the right side. On the same day he was trephined. At the end of December he was admitted to the Rothschild hospital. The wound had then healed, but there was a loss of bone substance about the size of a two-franc piece at the site of which the scar, thin and depressed, was adherent to the brain. On January 3rd the author operated, using pieces of cartilage taken from a young soldier on whom he had performed rhinoplasty. Under local anaesthesia he excised the cicatrix, detaching

the scalp for some distance around the wound. The breach in the bone was filled up with bits of cartilage placed in apposition, and the integument brought together and sutured over them. Cure was complete at the end of a week; the breach remained firmly closed and the surface of the skull was regular. The grafted part could be pressed on, even forcibly, without causing any pain. (2) A soldier, aged 22, was wounded on November 2nd, 1915, by the bursting of a hand grenade, which struck the skull a little to the left of the middle line, at the junction of the occipital and parietal bones. He was trephined in an ambulance, when the foreign body and a number of splinters were removed. When admitted to the Val-de-Grâce hospital on November 23rd the wound was healing well, but there was a loss of substance in the skull nearly five centimetres in length by two and a half in breadth. It was oval in shape, the long axis running from before backwards. On January 18th Morestin operated under local anaesthesia, using the same procedure as in the first case. He filled up the breach with a large piece of cartilage taken from another patient, which had been preserved in sterilized milk for twenty-four hours. It was trimmed to fit the wound, and was not fixed except by the soft parts brought over it and hermetically stitched. At the end of a week no further dressing was needed. At the date of report scarcely a trace of the operation wound could be discovered among the hair, and the skull was smooth and offered a uniform resistance. Pressure over the site of the graft was painless. (3) A man wounded by a shrapnel bullet a little below the left frontal eminence was admitted to Val-de-Grâce on September 3rd, 1915. There was then a curvilinear scar at the lower part of the forehead, left by an operation performed soon after the infliction of the wound. At the inner part of the scar there was a fistula communicating with the left frontal sinus. There was a large loss of substance at the lower part of the frontal bone, with a corresponding deep depression where the pulsation of the brain could be felt and seen. The sight of the left eye was destroyed, although the eyeball looked normal. Radioscopy showed the projectile lodged in the left maxillary sinus. On September 17th it was extracted by Morestin, through an incision into the front wall of the sinus made through the vestibule of the mouth. The projectile was lodged in the lower part of the sinus. It was easily seized and drawn out with forceps. The vestibular wound was then completely reunited. The results were excellent, but the frontal fistula remained. Through it the left frontal sinus, or what was left of it, communicated with the exterior and a small drop of mucus or muco-purulent liquid was discharged every day. On November 22nd the inner part of the frontal cicatrix was removed, the fistulous track incised, and the sinus opened up and at once closed again by bringing the soft parts together and suturing them. This was followed by healing of the fistula. On December 21st the frontal scar was extirpated and the integuments mobilized. A considerable piece of cartilage taken from another subject and suitably trimmed was used to make an upper orbital arch exactly adapted to the edge of the breach. The wound was then closed hermetically. In a few days cicatrization was complete, and the deformity, except for slight mobility of the grafted piece on the neighbouring bone, has been completely corrected. (4) A soldier wounded by a shell on the right part of the forehead was brought to Val-de-Grâce on October 16th with a wound healing normally. It was like an irregular V in shape, the point being directed towards the eyebrow, which was divided into two unequal parts. There was an important loss of substance in the skull, and a cerebral hernia of the size of a large nut was seen in the centre of the wound. At the beginning of January there was a large irregular scar in the right half of the brow depressed in its centre and adherent to the brain. The scar was excised, the surrounding integuments widely mobilized, and the breach, which measured 4 by 5 cm., filled with pieces of cartilage from another subject. The results were satisfactory, the deformity being corrected except for the line of the scar, which was gradually disappearing at the date of report. (5) A soldier, aged 24, struck by a fragment of shell, was admitted to the Rothschild Hospital on March 22nd, 1915. Among other wounds he had a large one of the forehead with fracture and loss of substance in the skull. The wound had long healed, but there was a frightful scar with deep depression on the middle of the forehead. On January 22nd Morestin operated, filling in the breach, which was about the size of a two-franc piece, with cartilage. The scar was strongly adherent to the brain, and in dissecting it off the subarachnoid spaces were opened and a little cerebro-spinal fluid escaped. The breach was filled in with pieces adapted as accurately as possible to the

wound, which was sutured hermetically. The result was excellent; the forehead was smooth and the natural shape. The strongest pressure could be made on the grafted part without causing any trouble. At a later meeting (*ibid.*, February 29th, 1916) Morestin showed two other cases in which he had successfully corrected a large loss of substance in the frontal bone by the transplantation of cartilage.

63. Fractures of the Patella in War.

RENÉ LE FORT (*Bull. et mém. de la Soc. de Chir. de Paris*, August 3rd, 1915) has had under observation at base hospitals nine cases of fracture of the patella. He groups them in three categories—(1) simple fracture, (2) compound isolated fracture, (3) compound fractures accompanied by fractures of the condyles or the tibia. There was only one case of simple fracture, and in that one more serious injuries led to the fracture being overlooked at first. When discovered, operation was postponed because of the presence of severe septic wounds close to the knee, and when the operation had been performed these wounds interfered with the after-treatment, and prevented early movements of the joint being carried out. The operation was finally performed on the thirty-sixth day when the temperature was still 38.4° C. (101.1° F.) to 38.5° C. (101.3° F.); but in spite of all these drawbacks, and of there having been separation of the fragments of bone to the extent of two fingerbreadths, the patient when last seen was apparently on the way to complete recovery. There were three cases of compound isolated fracture. In one the patella was broken transversely into two main fragments, separated only by a few millimetres; each fragment was broken into several smaller pieces, held together by fibrous tissue. In view of the small separation and the relative integrity of the peri- and pre-patellar fibrous tissues suture was considered unnecessary. In another case there was little infection, and the wound healed rapidly, and operative treatment of the fracture could then be undertaken under conditions almost as satisfactory as in simple fracture. A peculiarity of the case was that the fractured ends of bone were found to be of almost double the normal thickness as a result of violent separation of the bony lamellae by the force of the projectile. The surfaces were brought together again by pressure with the fingers. In the third case a ball had passed through the patella and the knee-joint. Splint treatment was employed, and the patient apparently made a quick recovery. The case was seen by the author five weeks after the infliction of the wound, and movements of the joint were begun. It was then found that the functional loss of power was very great, and the condition was perhaps made worse by the fact that the patient accidentally received a blow on the knee on the second day of getting up. A radioscopy examination a month later showed a multiple fracture of the patella, with the interposition of an osseous fragment between the condyle and the posterior surface of the bone. At the operation a small amount of liquid was found in the joint. Some adhesions had formed which were easily detached by the finger, and a large osseous plaque 1.18 to 1.37 inches across, 0.39 to 0.47 inch in height, and 0.07 to 0.11 inch in thickness, was removed in three pieces from the anterior surface of the condyle by means of scissors. Movements were begun forty-eight hours after the operation, and when the patient was last seen complete recovery seemed probable. Thus in all three cases complete restoration of function was expected. All three were cases of comminuted fracture. None suffered from acute arthritis; in two cases the wounds were infected, but the joint did not react, clinically at any rate; in the third there was a certain amount of plastic arthritis, perhaps connected with the secondary traumatism. In five cases compound fracture of the patella was accompanied by fracture of the condyles or the tibia. The first was not seen by the author until seven weeks after the injury, and a few days later it was necessary to amputate for an acute arthritis. In each of the remaining four cases the limb was preserved. One patient underwent total resection of the patella seventeen days after the accident and ten days before coming into hospital. The immediate results of the operation were unsatisfactory, but cure with ankylosis was almost obtained when the patient, who suffered from phthisis, developed meningitis and died. In each of the three remaining cases a certain amount of movement at the knee was preserved. There was a suppurating arthritis in the first two cases, and each of these was treated by a classical arthrotomy. The third case was less seriously infected, and splint treatment, instead of operative treatment, proved to be sufficient.

64. Shrapnel Bullet in the Heart.

RICHARD FREUND and CARL CASPERSOHN (*Muench. med. Woch.*, August 31st, 1915; abstract in *Amer. Journ. of Surgery*, February, 1916) report a case of bullet wound of the heart. The patient was a soldier, aged 20, who was struck by a shrapnel bullet in the region of the left lobe of the liver while bending forward. When he came under the care of the authors, a fortnight later, he seemed to suffer no distress referable to interference with the action of the heart. His pulse was 72 and regular; there was no dyspnoea, and no cyanosis. An x-ray examination showed that the bullet was lodged 7 cm. from the front wall of the chest in the region of the right ventricle; it followed the motions of the heart in all positions assumed by the patient, but had no independent motion. Deep inspiration caused it to move upward somewhat and on expiration it moved downward and seemed to lodge in the deepest part of the right ventricle near the septum. As the right ventricular wall averages from 3 to 6 mm. in thickness, and the shrapnel bullet 13 mm., the authors were led to the conclusion that the bullet must have lodged within the right ventricle. On operation they found this to be the case. The chest wall was opened by flap wound, and an incision 8 cm. long was made into the pericardium, the left pleura being separated gently and retracted with a gauze compress. The heart was held with the left hand and brought forward; the bullet was located in the right ventricle. A small incision was made immediately over it, and at the depth of 4 mm. the knife touched the bullet. It was displaced with the blunt end of the knife and extracted. The bleeding, which was free, was immediately controlled with the left hand, and four sutures were rapidly passed through the opening to the endocardium and the knot tied by an assistant. The pericardium was also sewn up with silk stitches (ten in number), a small opening being left at the lower angle for drainage, and the chest flap restored in typical manner. There was no haemorrhage. The rubber drain was removed after three days, as it caused irregular action of the heart. The bandage was removed on the fourth day. After this the pulse again became irregular, breathing was more difficult, and there was oppression of the chest. This was found to be due to an accumulation of serum within the pericardium, which was relieved by reintroduction of the drain. Convalescence went on uninterruptedly except for an attack of suppurative parotitis on the left side, for which incision and drainage were required. In four weeks the patient was able to leave his bed, and in two months was quite well.

65. X-Ray Picture of Gas Phlegmons.

B. DÖHNER (*Muench. med. Woch.*, September 21st, 1915; abstract in *Amer. Journ. of Surgery*, February, 1916) found dark spots in the x-ray picture of gunshot wounds, indicating the presence of gas phlegmons. He cites the case of a soldier wounded in the thigh, in whom twenty hours afterwards the x-ray revealed two dark shadows. Operation revealed a deep-seated foul-smelling gas phlegmon, and fragments of clothing surrounding the bullet close to the femur. The wound had presented no alarming phenomena, nor was the track made by the bullet particularly unhealthy. The man made a good recovery. In view of the dangerous course of gas phlegmons Döhner recommends the early use of the x-ray for diagnosis in every case of gunshot wound. This, he holds, is quite as important as early antitetanus inoculation.

THERAPEUTICS.**66. Treatment of Nervous Disorder in Soldiers.**

CHAVIGNY (*Paris méd.*, January 1st, 1916) deals with the treatment of mental and nervous disorders in men on active service. Early treatment is an essential condition of success. Cases of mental confusion, deaf-mutism, and paralysis treated within four or five days of onset are generally cured in twelve or twenty-four hours. On the other hand, in men who have been kept under observation without active treatment for several weeks, recovery was much slower. Whenever any objective lesion coexists with the subjective disturbance, both conditions must be treated at the same time. For instance, if a patient with hysterical paralysis of a limb suffers also from dyspepsia, the digestive disorder should be energetically treated as well as the nervous trouble. In all cases of hysterical paralysis progressive re-education is the basis of treatment. But medicine should also be given to act on the mind; for this purpose a draught containing 1.50 gram of eucalyptol is recommended by Chavigny. When the nervous trouble is accompanied by anaesthesia,

re-education of the sensibility of the skin or special sense is called for. Hysterical coxalgia and hysterical paralysis of limbs get well unfailingly as soon as sensibility is restored in the anaesthetic areas adjoining the affected part. This is effected by means of the faradic current. Among the first cases treated Chavigny noted some in which the strongest faradization produced no effect. He has since applied the current in the following manner: Following indications given by the patient, the boundary line separating the part towards the root of the limb in which sensation is intact from the anaesthetic zone is determined and marked out with ink on the skin. The electrodes are then carried towards the line, sometimes encroaching on the sensitive area, sometimes being brought down over the anaesthetic patch. In a few minutes sensibility becomes normal over a band measuring some centimetres. The new limit of sensibility is then marked off, and the treatment is repeated either in the evening or on the following day. Progress is regularly recorded, and after a few sittings it is found that the anaesthesia has disappeared. This is invariably followed by disappearance of paralysis or hyperaesthesia in the limb. Chavigny, while admitting the possibility of the effect being due to suggestion, insists that the method is "efficacious, invariably efficacious, rapidly efficacious." He has treated deafness when it seemed to be of nervous origin by re-education. The apparatus employed is a large tuning-fork with strong vibrations. This is applied to the vertex or the mastoid process. Two or three daily sittings of vibratory massage by this method usually bring about rapid improvement. Musical re-education with the aid of a harmonium or other instrument with loud vibrations is employed at the same time. At the first sittings the patient applies his ear directly to the case and tries to perceive the vibrations. As hearing improves he gradually increases the distance from his ear. By this method of re-education Chavigny claims to have cured cases of relatively old standing which have been treated in other ways without success. In cases of dumbness the movements of speech have been forgotten and must be learnt anew. The doctor, placing himself in front of the patient, asks him in writing or by word of mouth, according as the man is deaf or not, to make with him the movements necessary for the production of the sound *a*. At the moment when he gives the signal for this effort he passes a faradic current of medium intensity through the front of the patient's neck in the prelaryngeal zone. After this other vowel sounds are attacked; then syllables, such as *ba*, *bo*, for the production of which very visible movements of the lips are required. The success of the method is said to be "absolute," and most patients can speak distinctly after one or two sittings. If a faradic battery is not available, the procedure which goes by the name of Garel of Lyons can be employed. At the moment when the patient attempts to imitate the movements of the doctor's lips, the latter presses his closed fist firmly on the man's epigastrium. This sudden and unexpected pressure almost invariably leads to the production of the sound *a*. Stammering of emotional origin requires special gymnastic treatment—rhythmic breathing, vocal sounds produced in measured time, combined with movements of the arms or trunk, lastly singing with musical accompaniment. In paralysis of limbs re-education of movement is carried out by re-education of sensibility. This should be combined with gymnastics progressive in range, the handling of weights of increasing heaviness, etc. Tics, tremors, and chorea, hystero-traumatic in origin, are successfully dealt with by gymnastic exercises. The patient executes carefully measured movements directed to antagonize the involuntary movements. He also practises immobility, trying before a glass to keep himself at rest, at first for short periods which are gradually prolonged. Psychological disturbances following great explosions occur mainly in the form of mental confusion and delusions. In 95 per cent. of cases those conditions are rapidly curable. Of 60 cases treated by Chavigny, only 2 had to be placed in confinement. All the others got well in six days at the outside; this fact he regards as an argument in favour of the treatment of such cases in a hospital ward rather than an asylum. The treatment consists in keeping the patient quiet in bed, with purgation when there is constipation or diarrhoea, and tepid or cold douches. When the mental disturbance is passing off the cure may be accelerated by subjecting the patient to a slight emotional shock, as by speaking to him about his family. By this means Chavigny has several times seen men roused from a state of almost absolute indifference to surprising lucidity. The change was due to the effort they were induced to make to write or dictate a few words home.

AN EPITOMÉ OF CURRENT MEDICAL LITERATURE.

War Number.

MEDICINE.

67. Acute Nephritis in Soldiers on Active Service.

M. GAUD and P. MAURIAC (*Paris méd.*, April 15th, 1916) record their observations on acute nephritis as seen in a large number of patients brought to an evacuation hospital from three army corps between September and November, 1915. There were 130 cases in a total of 2,000 patients, not including men suffering from chronic nephritis or from albuminuria developed in the course of paratyphoid, pneumonia, diphtheria, or other infectious states. The number of cases of acute nephritis observed daily increased in a marked degree in January and February, 1916. They never observed atypical cases; with differences of gravity the patients presented a uniform symptomatology and the same essential features. In general a soldier who had previously been in good health began to complain of fatigue, obstinate headache, pains in the loins, and a slight feeling of oppression. In two cases there were digestive phenomena—anorexia and vomiting. This prodromatous stage lasted from three to six days. Suddenly, in a few hours, oedema supervened. In many cases, as the general phenomena were not well marked, it was the infiltration of the limbs or face which made the patient apply for treatment; often attention was first called by comrades to the swelling of the face. When the disease was established, in almost all cases the general condition remained very good even when the symptoms were strongly marked. Fever was the rule in the first days, varying from 37.5° to 38.5° C., the maximum figure. The oedema was almost constant, and often invaded the face, the upper and lower limbs and the scrotum. It was most marked on the face. The authors never observed ascites or hydrothorax. Except for slight pains in the loins at the outset, clinical examination of the urinary apparatus was most often negative, but as regards the urine itself in the early stage there was oliguria, the patient passing from 500 to 800 grams of urine thick, often muddy, and of high colour. This rapidly passed away, a fact which explains that it seemed to be wanting in subjects who had come rather late to hospital. Chemical examination showed albumin from 2 to 5 grams in the litre on the average, but frequently from 10 to 15 grams. In one case there were 45 grams to the litre and 67 in the twenty-four hours, although there were no pus globules, and red corpuscles were rare. Microscopic examination showed epithelial cells, epithelial and granular cylinders, and some red corpuscles. In three cases the corpuscles were abundant and the urine distinctly haemorrhagic. The pulse was regular, rather fast and weak. On auscultation the *bruit de galop* was sometimes noticed in the graver cases. In the respiratory apparatus there was generally nothing of note, but in some patients fine râles were noticed at the two bases without expectoration. There was no pleural effusion. In only one case was vomiting noticed, and that rapidly ceased. The anorexia of onset was transient, and after one or two days of rest all the patients demanded food. Stools were normal, but in one case there was blood in the faecal matter as well as in the urine. No symptom referable to the liver. The organs of the senses showed nothing noteworthy. Under the influence of rest and milk diet the evolution of the disease was rapid, its course being a fortnight on the average. Fever subsided in five or six days, but in several cases the fall of temperature was interrupted by slight rises, constantly accompanied by an increase of albumin. Oedema rapidly vanished, the face being the last to clear. The amount of urine increases progressively, and the patient passes 2 to 2½ litres in the twenty-four hours. The albumin diminishes gradually, passing in a week from 5.6 grams to 0.75, 0.50, 0.25. Several times it disappeared altogether. In cases of massive albuminuria the evolution is somewhat longer; but, setting these exceptional cases aside, all the patients were discharged with less than 0.25 gram of albumin notwithstanding a partial return to ordinary diet. Arterial tension showed a decreasing curve, returning to normal in a few days. With regard to the classification of

clinical forms, the authors would only retain that marked by serious and somewhat dramatic onset, with considerable oedema and marked dyspnoea, cyanosis, and slight pulmonary congestion and oedema. But these cases are differentiated from the normal type only by exaggeration of the symptoms, and none of the cases observed by them resisted a milk diet for more than four weeks—milk diet and rest, and the administration of 0.50 gram of theobromine in twenty-four hours. This was the only remedy used in all their cases. There were practically no complications with the exception of grave uraemia. In one the patient was brought in comatose with very severe convulsive crises. There were 8 grams of albumin in the litre of urine. Two venesections brought about an immediate improvement, and four days after admission the man was clamouring to rejoin his regiment, that he might eat and smoke. He was discharged in two weeks in very good condition but with traces of albumin in the urine. In a second case, with the same symptoms, the patient died in thirty-six hours in spite of free venesection. This is the only case of death in the series. The authors conclude from their experience that the disease, at least in the phase in which they saw it, has a relatively favourable prognosis. But they hesitate to pronounce whether the patients would remain permanently free from albuminuria or become chronic nephritics. They bear strong testimony to the benefit derived by their patients from early treatment and rest. They hold that the men should not be exposed to chills and fatigue from long transport. They think their favourable results were due to the proximity of their hospital to the front. They sum up as follows: In troops on campaign there is a type of acute nephritis remarkable by its frequency, the considerable amount of albumin in the urine, the infectious course, and rapid evolution which is most often mild from the first. Fatigue, overwork, and defective food seem to create in soldiers a favourable soil, and in particular to make the kidney a frail and badly defended organ. The proof of this is the high proportion of men who have albuminuria without suffering any inconvenience till an infection comes which at once strikes the weak point—namely, the kidney. There are, perhaps, many germs to be held responsible. In the blood of two patients and the urine of three others the authors isolated bacilli approximating in character to the organisms of typhoid and paratyphoid. Their researches, though not allowing them to consider these germs as constant factors, seem to them to prove that at the outset there is, at least in certain cases, an infectious cause.

68. Extrasystoles after Injury by Shrapnel.

O. JOSUE and JEAN HERTZ (*Arch. des mal. du coeur, des vaisseaux et du sang*, 1915) have made a careful study of a case of attacks of extrasystoles in a soldier who was wounded by a shrapnel bullet in the neck. The wound appeared to involve the ninth, tenth, eleventh, and twelfth cranial nerves on the left side, and gave rise to different paralyses—pharyngeal, laryngeal, spinal, and labial—and to disturbances of the pupil, in addition to the cardiac symptoms. The man was first seen by the authors eight months after the infliction of the wound. The respiratory system, and, in repose, the heart also, appeared to be normal; the pulse-rate was 76 to 80. The maximum arterial tension varied from 9 to 13.5 by the Riva-Rocci method. The special troubles of rhythm were only caused by exercise, as when the patient walked a little quickly or walked upstairs. With exercise, the pulse-rate rose to 120 or more. If the patient then sat or lay down, the rate fell progressively to 90 and 80, and at the end of three or four minutes intermittence developed. This phenomenon occurred constantly after exercise following on a period of rest, but it could not be provoked if the exercise were at once repeated, though on one or two occasions, if the exercise were repeated a few minutes after the disappearance of the extrasystoles, there was a slight return of the attack in a modified form. As a rule, the crises last only from one and a half to two minutes. On two occasions a crisis was prolonged to six or six and a half minutes by pressure on the ocular globes. Inhalation of amyl nitrite brought the crises instantaneously to an end.

and the injection of atropine beforehand greatly shortened the attacks. The Wassermann reaction was positive, but there was no obtainable history of syphilis nor any signs of it, and a course of treatment by injections of biniodide of mercury had no influence upon the extrasystolic crises. A number of tracings were taken with Mackenzie's apparatus. Two of these showed that the pulsations which followed the extrasystoles were equal in height to the others, and that there was a complete absence of the post extrasystolic alternance seen when the myocardial function is sensibly altered. Electro-diagrams gave important results. The extrasystoles were shown to be, for the most part, different forms of the diphasic type, the first variation being directed upwards and the second one, much less pronounced in height, directed downwards. Extrasystoles of this type are held to originate from the base of the right ventricle. Other extrasystoles, which were distinguished by their reduced height and shorter duration, approach very nearly those obtained by Lewis from excitation of the anterior surface of the right auricle. At intervals tracings were obtained of extrasystoles which originated from the lower part of the auriculo-ventricular bundle. Two tracings showed a combination of extrasystoles of all origins separated by shorter or longer intervals, but with no normal systole, ventricular or auricular, interposed amongst them. The result is therefore as if there existed in the myocardium different small areas, distributed from above the auriculo-ventricular bundle to the middle part of the right ventricle, from which the extrasystoles originated. With regard to causation, syphilis is negated by the history of the case, and by the absence of any stigmata, of any result from antisyphilitic treatment, and of post extrasystolic alternance. If it be accepted that the extrasystoles were of nervous origin, excitation of the sympathetic fibres or of the vagus might be held responsible. Physiological experiments have shown that extrasystoles of the type met with in this case can be produced by excitation of the sympathetic fibres. On the other hand, the effect of amyl nitrite, atropine and ocular compression is principally upon the vagus nerve, while recent workers have shown that the left vagus acts more especially on the auriculo-ventricular bundle and the ventricle. But although two or three isolated cases appear to point to a different conclusion, orthodox opinion does not accept the production of extrasystolic crises as among the consequences of excitation of the vagus; and in this case, although ocular compression prolonged a crisis, the crises were regularly produced and only produced by exercise. During the earlier stages of the illness the patient had suffered from nocturnal attacks of dyspnoea and cardiac disturbance apparently similar to those seen by the authors. This fact is of interest, since it is recognized that during sleep disturbances of the cardiac function are experienced which are similar to those caused by fatigue during the day. The prognosis in this case is guarded because of the extent of the irritable zone existing in the myocardium.

69. Tremor in Soldiers.

At a meeting of the Medical Society of Leipzig N. v. MAYENDORF (*Muench. med. Woch.*, February 29th, 1916) drew attention to the frequency with which different kinds of tremor were found in military hospitals. He recognized three classes of tremor showing distinctive clinical features. In the first there was tremor of the right arm when the elbow was flexed to a right angle or when the arm hung freely down; it was characterized by rhythmic oscillations with wide excursions. This form of tremor was sometimes the only symptom; at other times it was accompanied by well-defined hysterical phenomena, the arm in such cases being anaesthetic. There was no limitation of movement of this arm, no contractions, and no increase of the tendon reflexes. In the second class also the tremor showed wide excursions. It affected both legs, increasing and decreasing in intensity, and being usually accompanied by analgesia extending upwards as far as to the upper border of the patella. When the patellar reflexes were increased there was no corresponding increase of the Achilles reflexes or accentuation of Babinski's sign. The apparent limitation of movements about the knee-joints on passive movement was due to muscular contractions. The tremor diminished on walking, and was least when the legs were flexed at the knee to a right angle, when the patient sat on the edge of his bed, or when he stood up. To tremor of this variety might be applied the term "static tremor." In the third class there was general clonus, which either persisted as such or developed into tremor, limited to certain extremities, when the patient was subjected to severe exertion or other stimuli. The clonus of the right arm

exceeded in intensity the contractions of any of the other groups of muscles. In every case in this class the mental condition was much affected. Mayendorf had also seen one case of isolated tremor of the muscles of one side of the neck and one case of isolated tremor of one side of the face. In both these cases the affected parts were also analgesic. Discussing the etiology of these tremors, he suggested that there were many contributory factors, such as shell concussion, standing in water for hours, falls from horseback or carts, projectile wounds, etc. In only very few cases was there a psychogenetic basis to account for these symptoms, and on this account they should be regarded rather as a commotion neurosis due to physical concussion of the central nervous system than as an hysterical manifestation. As for the teaching that these tremors could be cured by suggestion, he had found that the results of this treatment were only transitory, the basic disease being unaffected by hypnosis. Accordingly he was very doubtful as to the wisdom of sending back to active service patients "cured" by this method. All these forms of tremor could easily be imitated. To distinguish between the true sufferer and the malingerer it was not enough to rely on certain trick tests, but every factor in the case, including the patient's personality, should be carefully analysed. It was, however, possible at once to exclude malingerers when the tremor was continuous for several hours.

SURGERY.

70. Extraction of Projectiles from Lung.

At a meeting of the Paris Surgical Society on September 8th, 1915 (*Bull. et mèm. de la Soc. de Chir.*, September 21st, 1915), G. MARION presented a soldier from whom he had extracted a bullet lodged in the lung at the depth of 9 cm. including the chest wall, and lying in contact with the left auricle. The case showed that the removal of projectiles from the lungs was easy, and not a severe procedure. Marion, who at first shared the general opinion as to the danger of the operation, was led gradually to the belief that all cases without exception could be dealt with. At first he operated only in cases in which the foreign body had produced foci of suppuration with adhesions to the chest wall. Later, after having removed projectiles lodged at a depth of 1 or 2 cm. in the lung substance, he went on to extract them at a depth of 7 cm., and he found that the operation was neither more difficult nor more serious. Discussing the risks caused by a foreign body embedded in the lung, Marion says that in two cases in which the patients only complained of some difficulty in breathing, he found the projectile encysted in an abscess from which pus escaped when the lung was incised. The technique is simple. Having localized the projectile, an incision is made parallel to the nearest rib above or below it; the rib is resected for a length of 4 or 5 cm.; the lung is next stitched to the chest wall with a Reverdin needle and three or four threads of catgut over the area of the rectangle which forms the field of operation bounded above and below by a rib and laterally by the ends of the resected rib. The lung is then incised, and the finger is pushed in, no heed being taken of bleeding or air bubbles. When the projectile is reached, it is seized with the finger bent to the form of a hook, and pulled out, regardless of tearing the lung; if it cannot be caught with the finger, the parenchyma is drawn out with Kocher's forceps while the projectile is pushed out with the index finger; when brought to the chest wall it is removed with the help of a grooved director or a bistoury. Finally the wound in the lung is plugged with a compress soaked in strong carbolic solution, and an ordinary dressing is applied to the one in the chest wall. In no case has the operation caused any trouble except some coughing with expulsion of a small amount of blood; this soon ceased. The patients were generally able to leave their beds in three or four days. The plug is removed from the lung wound on the fourth or fifth day; according to its depth it takes from a fortnight to a month to cicatrize completely. Marion said he had operated in twenty-seven cases, in only one of which he was unable to extract the projectile; this failure he attributes to his not having fixed the lung before opening the pleura, as he has always done since. Of the twenty-six projectiles removed seventeen were bullets, five fragments of shell, and five shrapnel bullets. In seventeen cases the projectile was encysted in the lung, free from any adhesion, and lying at a depth varying from one to seven centimetres. In four cases there were adhesions between the lung and the pleura, and the foreign body was in the middle of them; in three

it lay in an encysted purulent focus, the existence of which nothing in the patient's condition led the surgeon to suspect. In a further communication Marion (*Ibid.*, December 1st, 1915) said he had then operated in forty-three cases, and had never seen serious bleeding. In no case up to the date of report had the operation been followed by any ill effect. He had never had to deal with multiple projectiles, but if he met with such a case, and if all the foreign bodies were lodged in the same lobe, he would try to remove them by drawing out the lung. If they were scattered about in the parenchyma, he would take into account their size, the symptoms produced by them, and the lesions disclosed by radiology. In a paper read before the same society on November 10th, 1915, PIERRE DUVAL (*Ibid.*, November 16th, 1915) stated that he removed projectiles from the lung in fourteen cases. He agreed with Marion that such foreign bodies should always be extracted, but he used a different technique. The projectile might lie in a portion of lung adherent to the chest wall with or without a cutaneous fistula; or it might be lodged in non-adherent lung. In the latter case the patients complained of persistent deep-seated pain in the chest, which did not always correspond with the situation of the foreign body. The respiratory movements were short and jerky; both the pain and the dyspnoea were aggravated by effort. These symptoms made the men unfit for military service. Duval criticized Marion's technique, especially the thrusting of the finger into the lung, which he thought not only caused laceration of the parenchyma but extensive haemorrhagic infiltrations. In three cases he deliberately opened the pleura, produced a total progressive pneumothorax, drew the pulmonary lobe out of the chest, palpated and found the projectile, cut down on it through the part where there was least lung substance to traverse, extracted the foreign body, sutured the wound in the lung, which was replaced in the thorax, completely stitched up the chest wall and aspirated the intrapleural air by puncture. In a week the patients were able to leave their beds, and in a fortnight cure was complete. Auscultation and percussion showed an absolutely normal state of things. In twenty odd cases he had one death from double pneumonia following the operation; the projectile was lodged in a piece of lung adherent to the chest wall. Full details of the cases were given. At a meeting of the same society on January 26th, 1916 (*Ibid.*, February 1st, 1916), PL. MAUCLAIRE showed five cases in which removal of projectiles from the lung had been followed by haemoptysis, serous effusion into the pleura or extensive pneumothorax. These complications were not severe, but this might not always be the case. For that reason he thought that surgical intervention was called for only when the foreign body caused great pain, repeated effusion, or pulmonary congestion. Patients should be kept under observation for some time. With regard to the operative procedure, Maucclair said that if the incision of the pleura were small, pneumothorax might be avoided. The expansion of the lung could be helped by directing the patient to make long expirations while pinching his nose; this closed the glottis, and pushed the lung towards the chest wall.

At a meeting of the Société de Médecine et de Chirurgie de Bordeaux on January 21st (*Gaz. hebdom. des sci. méd.*, April 2nd and 16th, 1916) PETIT DE LA VILLÉON read a communication in which he stated that in a surgical service in the principal naval hospital at Brest under his direction he had among 1,700 wounded men treated by him about 80 cases of penetrating wound of the chest. In a large proportion of these fragments of projectiles were lodged in the lung. During the first year of the war he acted on the doctrine of non-intervention, but further experience led him to change his mind. His first operation for extraction of the foreign body was done on June 3rd, 1915. At that time Marion was the only surgeon in France who had extracted projectiles from the lung, and his results were still unpublished. Petit de la Villéon operated in 10 cases, in all with a successful result. He employed two different procedures—thoracotomy with resection of ribs and incision into the lung, removal of the projectile, followed by pleuropulmonary suture, and restoration of the chest wall; and extraction under the radioscopic screen. While each of these procedures has its advantages, the author prefers the screen operation on account of its simplicity, safety, and rapidity; it takes only a few minutes, more often only a few seconds. The local post-operative reaction was almost insignificant, and all the patients were able to leave their beds on the fourth or fifth day. Petit de la Villéon's experience has convinced him that the lung is a very tolerant organ, which with proper precautions can be freely operated on without danger.

71. Extraction of Projectile from the Heart.
